THE
LONDON ENCYCLOPÆDIA.

VOL. III.

ARSENIC TO BELL.

J. Haddon, Printer, Castle Street, London.

THE
LONDON ENCYCLOPÆDIA,

OR

UNIVERSAL DICTIONARY

OF

SCIENCE, ART, LITERATURE, AND PRACTICAL MECHANICS,

COMPRISING A

POPULAR VIEW OF THE PRESENT STATE OF KNOWLEDGE.

ILLUSTRATED BY

**NUMEROUS ENGRAVINGS, A GENERAL ATLAS,
AND APPROPRIATE DIAGRAMS.**

Sic oportet ad librum, presertim miscellanei generis, legendum accedere lectorem, ut solet ad convivium conviva civilis. Convivator amittitur omnibus satisfacere; et tamen si quid apponitur, quod hujus aut illius palato non respondeat, et hic et ille urbane dissimulant, et alia fercula probant, ne quid contristent convivatorem. Erasmus.

A reader should sit down to a book, especially of the miscellaneous kind, as a well-behaved visitor does to a banquet. The master of the feast exerts himself to satisfy his guests; but if, after all his care and pains, something should appear on the table that does not suit this or that person's taste, they politely pass it over without notice, and commend other dishes, that they may not distress a kind host. Translation.

BY THE ORIGINAL EDITOR OF THE ENCYCLOPÆDIA METROPOLITANA,

ASSISTED BY EMINENT PROFESSIONAL AND OTHER GENTLEMEN.

IN TWENTY-TWO VOLUMES.

VOL III.

LONDON :

PRINTED FOR T. TEGG & SON, 73, CHEAPSIDE ;

SYDNEY AND HOBART TOWN.

1837.

THE
LONDON ENCYCLOPÆDIA.

A R S E N I C.

ARSENIC, *αρσενικον*, ARSENICUM, in mineralogy and chemistry, called by Aristotle *σανδραχη*, by Theophrastus *αρσενικον*, by the Romans orpimentum and arsenicum; is a reddish-colored ponderous mineral, caustic, corrosive, and highly poisonous; which was used by the ancients in medicine and painting. Aristot. de Hist. Anim. l. 8, c. 24; Theophrast.; Dioscor. l. 5, c. 121; Plin. l. 34, c. 18; Cels. de Re Med. l. 5, c. 5; Gal. de Comp. Med. sec. Loc. l. 4. In the Linnæan system, it is a genus of metals having these generic characters: Bluish white, some becoming black, and falling to powder in the air; soft and extremely brittle; specific gravity 8·310: subliming without melting in a moderate heat in a white powder, and emitting a strong garlic smell. Its sublimed oxid gives an acrid taste to water, and turns vegetable blues red. When dissolved in muriatic acid, and a watery solution of sulphurated hydrogen poured into it, it precipitates a fine yellow powder.

The principal species are, 1. *A. nativum*, native arsenic, of the three varieties: *α*. Uncombined, having a metallic lustre and separating into spherical incrustations. *β*. With micaceous particles. *γ*. Friable and porous. Found in the British Isles, Norway, Germany, Saxony, &c. in spar, baryte, or feldspar, massive, rarely disseminated, often composed of hemispheric layers, corroded, branched, perforated, botryoidal, or stalactitic; color lead-gray, but its surface soon tarnishing and becoming black by exposure to the air; streak bluish-gray, powder dull and blackish; sometimes a little sonorous when struck against a hard body, and so soft as to be easily cut with a knife. Before the blow-pipe it emits a white smoke, diffusing its peculiar and highly poisonous vapors to a great distance; burning with a blue flame and gradually vanishing, depositing a white oxid in the form of a powder: specific gravity 5·670 to 5·729; always alloyed with some iron, and often contains some cobalt, bismuth, silver, and sometimes a little gold.

2. *A. calciforme*; white arsenic; white oxid of arsenic; white, soluble in eighty times its weight of water. It is found in a loose dust or mealy powder; in a state of crystallisation; or in an indurated state combined with earth; in various parts of Great Britain, Germany, Hungary, Saxony, Bohemia, &c. Color white or gray, with often a tinge of red, yellow, green, or black: before the blow-pipe it sublimes, but does not inflame, and tinges borax green: specific gravity 3,700.

3. *A. auripigmentum*; orpiment, yellow arsenic. Ponderous, yellow, curved, or undulately foliated, of a waxy internal lustre, evaporating almost entirely before the blow-pipe. Found in Great Britain, Hungary, Georgia, Turkey, &c.; massive, disseminated, or in small imperfect crystals; color, various shades of yellow, with a considerable waxy lustre, and some transparency; streak orange-yellow, not metallic; texture foliated, with the plates mostly curved or undulated, rarely striate, a little flexible, but not elastic; effervesces with hot nitric acid, burns with a bluish flame, and before the blow-pipe evaporates, leaving behind a small portion of earth: specific gravity 3·048 to 3·521.

4. *A. sandaraca*; red arsenic; ruby arsenic; realgar. Somewhat ponderous, red, with an orange-yellow streak, in straight foliations, melting easily before the blow-pipe; burning with a blue flame and white arsenical vapors. Found in Sicily, Naples, Hungary, Bohemia, China, Japan, &c.; massive, disseminated, superficial, or crystallised in small acute-angled, quadrangular, or acicular prisms; color auro-red, ruby, scarlet, crimson or blood-red, often variegated with yellow traces: texture lamellar, with the foliations a little flexible, and so soft as to be cut with a knife, and frequently exhibiting a brilliant lustre; streak yellowish-red; powder scarlet; in nitric acid it loses its color; specific gravity 3·338.

5. *A. sulphuratum*; marcasite; white mundic; white pyrite; pyritical arsenical ore. Hard, bluish-gray with metallic lustre, before the blow-pipe emitting white arsenical vapors and blue sulphureous flames. Found in various parts of Great Britain, Germany, Sweden, Bohemia, Saxony, &c. in irregular masses, disseminated, investing or crystallised in cubes or four-sided prisms; specific gravity 6·522.

6. *A. albicans*; misspickel; marcasite. Of a steel-white color and lustre, hard, emitting white arsenical vapors before the blow-pipe, but no sulphureous flame or vapor. Found in Cornwall, near Dublin, in Bohemia, Silesia, Saxony, &c. generally dispersed among tin ores in granulations, or crystallised in four-sided double pyramids, or four-sided quadrangular prisms: color sometimes silvery, gray, or yellowish, or iridescently variegated when tarnished: texture compact, sometimes a little splintery, with the surface marked with decussate grooves or black ramifications; effervesces with nitric acid without heat, and yields

an arsenical smell when rubbed. It consists of arsenic alloyed with a considerable quantity of iron, but little or no sulphur; specific gravity from 5.753 to 6.522.

7. *A. argentiferum*; argentiferous arsenic. Of a silvery lustre and very fine granular texture, emitting arsenical vapors before the blow-pipe, and when fused with lead leaving a silver bead. Found in the mines of Saxony, Bohemia, Germany, and Spain; massive, disseminated, or acicular; color nearly that of the last, but brighter and more permanent; burns with a white flame, and leaves a reddish residuum: by solution in nitro-muriatic acid the silver will be precipitated. It consists of arsenic, sulphur, iron, and from 1 to 10 or 12 per cent. of silver: specific gravity 4.087.

The following is the method of the celebrated Mr. Chevenix for the assay and analysis of arsenical ores. Reduce the ore to a very fine powder, and digest it in nitric acid sufficient to acidify and take up the whole of the arsenic; pour off the clear liquor, and boil on the residue some distilled water: filter, and add the water to the nitrous solution: then neutralise the excess of acid by potash, taking care, however, not to have an excess of alkali, and add nitrate of lead as long as any precipitate takes place: wash the precipitate in cold water, dry, and weigh it. As the arsenical ores often contain sulphur, it is possible that the arseniat of lead thus procured may be mixed with a little sulphat of lead: to decide this, digest the powder in some warm dilute muriatic acid, and the arseniat of lead will be dissolved, leaving the sulphat behind.

The arsenic of commerce is prepared in Saxony by roasting the cobalt ores in the manufacture of *zafre*. These ores consist principally of arsenic, cobalt, iron, and a little sulphur; the first and last ingredients are easily separated by roasting, which is performed not in the open air, but in an oven, the flue of which runs horizontally to a considerable distance before it bends upwards. The arsenic and sulphur, when liberated, are deposited for the most part in the horizontal flue. In this state it is called

Crude arsenic, or flowers of arsenic, and the form it assumes is that of a grayish meal streaked with yellow, which is occasioned by the sulphur uniting with parts of the arsenic, and composing *orpiment*. From the crude arsenic the

White arsenic of commerce is prepared by mixing the crude with potash or lime, and re-subliming. The sulphur and other impurities are thus combined with the alkali, and the white oxide is driven over into a heated receiver, where it melts into a heavy, colorless, transparent glass: by exposure to the air for a short time this glass becomes opaque, and resembles in its fracture the finest white china: it is in this state that the white arsenic of commerce is sold in the shops, and kept in our laboratories; and as it is then an oxide of the metal approaching very nearly to a state of purity, it is not difficult, by separating its oxygen, to reduce it into

Pure metallic arsenic. For this purpose the white arsenic is mixed with any of the vegetable

or animal expressed oils, till it becomes of the consistence of very soft glazier's putty, and round or oblong pieces of the paste are dropped into a Florence flask, or earthen retort, so as not to adhere to the sides. It is then put into a sand-bath, or over a gentle charcoal fire, and heated very gradually until it ceases to emit thick vapors, when the heat may be increased by degrees to obscure redness. Shortly after the vessel may be removed, and when cold, broken; the neck and upper part will contain a crystallised oxide of arsenic; below, a thick crust of metallic arsenic; and at the bottom some impurities, which must be laid aside. The other products are to be pulverised with half their weight of charcoal, and sublimed again as before; by which means the arsenic is rendered pure, and will be found to line the vessel in the form of a shining crust and crystals.

The principal properties of pure arsenic, beside those mentioned in the beginning of this article, are the following:—That it is not perceptibly soluble in water, and is easily tarnished by exposure to the air; the best method of preserving it unaltered is to immerse it in water or alcohol. With carbon or hydrogen it does not combine; but the latter substance, in the state of gas, dissolves it. Oxygen unites with it by combustion, forming arsenical acid. With sulphur it may be readily united, forming either *realgar* or *orpiment*, according to the proportions of the ingredients, or the methods of uniting them: these substances are really sulphurets of arsenic, and their properties, with their mode of preparation, when not found native, may be found under their names. Arsenic combines also readily with phosphorus, forming phosphuret of arsenic, which is black and brilliant; but with azotic gas it has not been united. Muriatic acid attacks arsenic only if aided by heat; but, by distilling equal parts of *orpiment* and corrosive muriate of mercury (corrosive sublimate) in a gentle heat, a blackish corrosive liquor is obtained, which is the sublimated muriat of arsenic, or butter of arsenic. Arsenic combines with most metals, forming with them alloys, and rendering them more fusible and brittle; though such of them as were before very fusible become refractory: it possesses also the singular property of destroying the magnetic virtue of iron, and of all other metals susceptible of it.

The most useful alloys of arsenic are:—1. With platinum, which is formed by fusing that metal and the white oxide of arsenic together. By this means platinum, itself so untractable, may be wrought into the utensils required. The mixture, after fusion, is hammered at a red heat into bars, and the arsenic is gradually driven off. 2. With copper, which is formed by fusing the two metals together in a close crucible, their surface being covered with common salt, to prevent the arsenic from being oxidised by the air. This alloy is white and brittle, and when mixed with a little tin or bismuth is used for a variety of purposes in the arts, when it is known by the names of white copper or white tombac. 3. With iron, which is likewise done by fusion. This alloy, however, is often found native, and is then called *misspickel*. The other metals with

which arsenic has been united, are gold, silver, tin, lead, nickle, zinc, antimony, and bismuth: it also forms an amalgam with mercury, by keeping them some hours over the fire, constantly agitating the mixture. Arsenic is capable of combining with two different proportions of oxygen; by the first is formed the white oxide already described, or arsenious acid, as it is denominated by Fourcroy, on account of the many acid properties which it exhibits; by the second is produced arsenic or arsenical acid, which was discovered in 1775 by Scheele, who also made himself acquainted with its most remarkable properties.

In pharmacy, the white oxide of arsenic is directed by the London Pharmacopœia to be sublimed; after which it is to be boiled with an equal weight of carbonate of potash, in order to form the liquor arsenicalis, sometimes called Fowler's solution, or the tasteless ague drop. This contains one grain of arsenic in two drams, is given in doses of a few drops in intermittent fevers, and in several eruptive diseases. Caution is necessary in the exhibition of so dangerous a remedy. Arsenic has been used externally in cancer, lupus, &c. in form of an ointment. For an account of arsenic, as a poison, its symptoms, effects, and remedies, see **POISON**.

ARSENICAL MAGNET, MAGNES ARSENICALIS, is a preparation of antimony, with sulphur and white arsenic.

ARSENIUS, a deacon of the Roman church of great learning and piety, who was selected by the pope as tutor to Arcadius, son of the emperor Theodosius. Arsenius arrived at Constantinople A. D. 383. The emperor happening one day to go into the room where Arsenius was instructing his pupil, found Arcadius seated and his preceptor standing; at this he was exceedingly displeased, took from his son the imperial ornaments, made Arsenius sit in his place, and ordered Arcadius for the future to receive his lessons standing uncovered. Arcadius, however, profited but little by his tutor's instructions, for some time after he formed a design of despatching him. Arsenius, however, hearing of the design, retired to the deserts of Scetê, where he passed many years in devotion, and died aged ninety-five.

ARSENIUS, bishop of Constantinople, in the thirteenth century, excommunicated Michael Paleologus, for taking the imperial crown from John Lascaris the son of Theodore. Though Michael solicited absolution, the bishop refused, unless he would restore the crown; in consequence of which Arsenius was banished to a small island, where he died.

ARSENOTHELYS, among ancient naturalists, the same with hermaphrodite. The Greeks use the word both in speaking of men and beasts, it is formed from *αρσεν* and *θηλυς*, male and female.

ARSEVAL, in geography, a town of France, in the department of the Aube, and chief place of a canton in the district of Bar-sur-Aube, twenty-three miles east of Troyes.

ARSES, or **ARSAMES**, king of Persia, succeeded Artaxerxes Ochus about A. M. 3612, and after a short reign of less than four years was slain

by Bagoas, who had murdered his predecessor, and succeeded by Darius Codomanus.

ARSHIN, in commerce, the most common Russian measure of length = 16 vershok = 315 $\frac{1}{4}$ Paris lines. It is also a Chinese measure, but one Chinese arshin = 302 Paris lines. Three arshins = 1 fathom, and 500 fathoms = 1 verst.

ARSIA, in ancient geography, a small river which had a northern course, and served as a boundary between Histria and Illyria, to the north of the Flanatic gulf. It there terminated Italy on the north-east of the Polatic promontory.

ARSINOË, in ancient geography, the name of various towns mentioned by Strabo, Ptolemy, Stephanus, &c. viz. of five towns in Cilicia, one of which had a station for ships; of three in or near Cyprus; viz. one inland, formerly called Marium, another north of it between Acamas and Soli, and the third in the south, with a port, between Citrum and Salamis. A sea-port in Cyrene, formerly called Teuchira. A town in Egypt near the west extremity of the Arabian Gulf, and south of Hierapolis, called also Cleopatris. Another in the Nomos Arsinoites, mentioned on some coins of Adrian, and formerly called Crocodilorum Urbs, from its abounding with crocodiles; Ptolemy calls this town an inland metropolis, with a port called Ptolemais. A sea-port of Lycia formerly named Patara, but called Arsinoë by Ptolemy Philadelphus after his queen. And three towns of Troglodyta, the chief of which was situated near the mouth of the Arabian gulf, which towards Ethiopia is terminated by a promontory called Dire. This Arsinoë is called Berenice, with the distinction Epidires; because situated on a neck of land running out a great way into the sea. Also the name of several princesses of Egypt; particularly, 1. the daughter of Ptolemy Lagus, and wife of Lysimachus king of Thrace: 2. the wife of Ptolemy Philadelphus, who named several towns after her.

ARSINOË, in entomology, a species of papilio, found in the island of Amboyna, the wings of which are tailed, indented, fulvous, spotted with black; and the posterior ones marked both above and beneath with two ocellated spots. It is figured by Seba and Cramer.

ARSINOITES, **NOMOS**, an ancient district of Egypt, west of the Heracleotes, on the western banks of the Nile.

ARSIS, and **THESIS**, in prosody, are names given to two proportional parts into which every foot or rhythm is divided. By arsis and thesis are usually meant no more than a proportional division of the metrical feet, made by the hand or foot of him that beats the time. And in measuring the quantities of words the hand is elevated, as well as let fall; that part of the time which is taken up in measuring the foot, by lifting the hand up, is termed arsis or elevatio; and the part where the hand is let fall, thesis or positio. Vid. Augustin de Musica, lib. ii. cap. 10. In plaudendo enim quia elevatur et ponitur manus, partem pedis, sibi elevatio vindicatur, partem positio.

Arsis and thesis are used as musical terms

when the subject of a fugue or point is inverted or reversed; i. e. when one part rises and the other falls. These two words are Greek: *arsis* comes from *αρω*, *tollo*, I raise or elevate; *thesis* depositio, remissio, a depression or lowering. These terms were applied by the ancients to the motion of the hand in beating time.

ARSON, in English law, is the malicious and wilful burning of the house or out-house of another man, which is felony. This is an offence of great malignity, and more pernicious to the public than simple theft; because, first, it is an offence against that right of habitation which is acquired by the law of nature as well as by the laws of society; next, because of the terror and confusion that necessarily attends it; and, lastly, because in simple theft the thing stolen only changes its master, but still remains *in esse* for the benefit of the public; whereas by burning, the very substance is absolutely destroyed.—It is also frequently more destructive than murder itself, of which too it is often the cause; since murder, atrocious as it is, seldom extends beyond the felonious act designed; whereas fire too frequently involves in the common calamity persons unknown to the incendiary, and not intended to be hurt by him, and friends as well as enemies. If the house be a man's own, the act is not felony and punishable with death, but only a great misdemeanor, and punishable by fine, imprisonment or pillory.

ARSUR, **ASOR**, **ARSAR**, or **ARSID**, a hamlet on the coast of Syria, which has sometimes received the name of a city, because Solomon is supposed to have built the city Asor upon the site. It contains a fortress and mosque, in the last of which are a few Mahomedan monks.

ARSURA, in ancient customs, a term used for the melting of gold or silver, either to refine them or to examine their value. The method of doing this is explained at large in the Black Book of the Exchequer, ascribed to Gervaise in the chapter *De Officio Militis Argentarii*, being in those days of great use, on account of the various places and different manners in which the king's money was paid. *Arsura* is also used for the loss or diminution of the metal in the trial. In this sense a pound was said, *tot ardere denarios*, to lose many penny-weights.

ARSURA, in medicine, is used by some writers for the *crisypelas*.

ARSURA, in metallurgy, is used for the dust and sweepings of silversmiths, and others who work in silver, melted down, and which they call their sweep.

<p>ART, ARTFUL, ARTFULLY, ARTFULNESS, ARTISAN, ARTIST, ARTLESS, ARTLESSLY, ARTIFICE, ARTIFICER, ARTIFICIAL, ARTIFICIALLY.</p>	<p>Lat. <i>ars</i>, from <i>αρηη</i>, many energy, strength, or skill. The power of doing any thing arising from a clear and perspicuous know- ledge of what the practice of it requires. Artful signi- fies evil intention. One who exercises a mechanical art is an artisan, he who ex- cels in the fine arts is an artist. Any skilful work- man is an artificer; artifice in its present use implies deception.</p>
--	--

HEL. We, *Hermia*, like two *artificial* gods,
Created with our needles both one flower,
Both on one sampler, sitting on one cushion;
Both warbling of one song, both in one key;
As if our hand, our sides, voices, and minds,
Had been incorporate.

Shakspeare.

Why, I can smile, and murder while I smile;
And cry, content, to that which grieves my heart;
And wet my cheeks, with *artificial* tears. *Id.*

Weaker than a woman's tear,
Tamer than sleep, fonder than ignorance,
And *artless* as unpractis'd infancy.

Dryden. Troilus and Cressida.

Rich with the spoils of many a conquer'd land,
All arts and *artists* Theseus could command,
Who sold for hire, or wrought for better fame
The master painters and the carvers came. *Dryden.*

The rest in rank: *Honorio*, chief in place
Was *artfully* contriv'd to set her face,
To front the thicket, and behold the chace. *Id.*
Vice is the natural growth of our corruption. How
irresistibly must it prevail, when the seeds of it are
artfully sown, and industriously cultivated. *Rogers.*

What are the most judicious *artisans*, but the
mimics of nature? *Wotton's Architecture.*

Best and happiest *artisan*,
Best of painters, if you can,
With your many-color'd art,
Draw the mistress of my heart.

Guardian.

Thus *artists* melt the sullen ore of lead,
With heaping coals of fire upon its head;
In the kind warmth, the metal learns to glow,
And loose from dross the silver runs below.

Parnell.

Sweet *artless* songster! thou my mind dost raise
To airs of spheres, yea, and to angels' lays.

Drummond.

In oratory, the greatest *art* is to hide *art*. *Swift.*
If we compare two nations in an equal state of civi-
lisation, we may remark that where the greater free-
dom obtains, there the greater variety of *artificial*
wants will obtain also. *Cumberland.*

The merchant, tradesman, and *artisan* will have
their profit upon all the multiplied wants, comforts,
and indulgences of civilised life. *Id.*

In every quarter of this blessed isle,
Himself [the mind] both present is and president,
Nor once retires, a happy realm the while,
That by no officers lewd ravishment,
With greedie lust and wrong consum'd *art*,
He all in all, and all in every part,
Does share to each his due and equal dole compart.

Fletcher's Purple Island.

Among the several *artifices* which are put in prac-
tice by the poets, to fill the minds of an audience with
terror, the first place is due to thunder and lightning.
Addison.

Poets, like painters, thus unskill'd to trace
The naked nature and the living grace,
With gold and jewels cover ev'ry part,
And hide with ornaments their want of *art*.

Pope's Essay on Criticism.

O still the same *Ulysses*, she rejoin'd;
In useful craft successfully refin'd;
Artful in speech, in action, and in mind. *Pope.*
Embosom'd in the deep where Holland lies,
Methinks her patient sons before me stand,
Where the broad ocean leans against the land,
And sedulous to stop the coming tide,
Lift the tall rampire's *artificial* pride. *Goldsmith.*

A man will no more carry the *artifice* of the bar
into the common intercourse of society, than a man
who is paid for tumbling on his hands will continue to
tumble when he should walk on his feet. *Johnson.*

He feels no ennobling principle in his own heart, who wishes to level all the *artificial* institutions which have been adopted for giving a body to opinion, and permanence to fugitive esteem. *Burke.*

ART has been more particularly defined to be a habit of the mind prescribing rules for the due production of certain effects; or the introducing the changes of bodies from some fore-knowledge and design in a person endued with the principle or faculty of acting. The word has been sometimes derived from *αγορ*, utility, profit; and is found in that sense in *Æschylus*.

According to lord Bacon it is a proper disposition of the things of nature by human thought and experience, so as to make them answer the designs and uses of mankind. Nature, according to that philosopher, is sometimes free, and at her own disposal; and then she manifests herself in a regular order; as we see in the heavens, plants, animals, &c.—Sometimes she is irregular and disorderly either through some uncommon accident or depravation in matter, when the resistance of some impediment perverts her from her course; as in the production of monsters. At other times she is subdued and fashioned by human industry, and made to serve the several purposes of mankind. This last is what we call art. In which sense, art stands opposed to nature. Hence the knowledge of nature may be divided into the history of generation, of pretergeneration, and of arts. The first considers nature at liberty; the second her errors; and the third her restraints.

Art has been distinguished from science; by the latter being regarded as furnishing the principles of all art. Or science, *scientia*, all human knowledge, is said to be divisible into those purer sciences which relate to the ideas or laws of the mind, and the relation they bear to each other; and the mixed or applied sciences—that relation which the same ideas bear to the external world. In this view the mixed and applied sciences are but other terms for all the fine and useful arts. Chambers has observed long ago, in the excellent preface to his original *Cyclopædia*: An Art and a Science, only seem to differ as less and more pure: a science is a system of deductions made by reason alone, undetermined by any thing foreign or extrinsic to itself: an art, on the contrary, requires a number of data, and postulata, to be furnished from without; and never goes any length, without at every turn needing new ones. It is, in one sense, the knowledge and perception of these data that constitutes the art; the rest, that is, the doctrinal part, is of the nature of science; which attentive reason alone will descry. An art, in this light, appears to be a portion of science, or general knowledge, considered, not in itself as science, but with relation to its circumstances or appendages. In a science the mind looks directly backwards and forwards to the premises and conclusions: in an art we also look laterally to the concomitant circumstances. A science, in effect, is that to an art, which a stream running in a direct channel, without regard to any thing but its own progress, is to the same stream turned out of its proper course, and disposed into cascades, jets, cisterns, ponds, &c. In

which case the progress of the stream is not considered with regard to itself, but only as it concerns the works; every one of which modifies the course of the stream, and leads it out of its way. It is easy to trace the progress of the former, from its issue, as it flows consequentially; but a man ever so well acquainted with this will not be able to discover that of the latter, because it depends on the genius, humor, and caprice of the engineer who laid the design.'

The learned author of *Hermes* says, If it be asked, What art is; we have to answer, 'It is an habitual power in man, of becoming the cause of some effect, according to a system of various and well-approved precepts.' If it be asked, On what subject art operates; we can answer, 'On a contingent, which is within the reach of the human powers to influence.' If it be asked, For what reason, for the sake of what, art operates; we may reply, 'For the sake of some absent good, relative to human life, and attainable by man, but superior to his natural and untrained faculties.' Lastly, if it be asked, 'Where it is the operations of art end?' We may say, 'Either in some energy, or in some work.' —*Harris's Three Treatises*, dialogue i.

Arts are properly divided into liberal and mechanical:—

ARTS, LIBERAL, OR POLITE, are those that are noble or ingenious, and worthy of being cultivated for their own sake, without any immediate regard to any pecuniary emolument. Such as depend more on the imagination, or on the labor of the mind, than on that of the hand; or that consist more in speculation than operation, and have a greater regard to amusement and curiosity than necessity. Such are poetry, music, painting, grammar, rhetoric, the military art, architecture, and navigation. They were formerly to be summed up in the following Latin verse:

Lingua, Tropus, Ratio, Numerus, Tonus, Angulus,
Astra.

In the eighth century the whole circle of sciences was composed of the seven liberal arts, as they were called; viz. grammar, rhetoric, logic, arithmetic, music, geometry, and astronomy; the three former of which were distinguished by the title of trivium, and the four latter by that of quadrivium.

ARTS, MECHANICAL, are those wherein the hand and body are more concerned than the mind; and which are chiefly cultivated for the sake of the profit attending them. Of which kind are most of those which furnish us with the necessaries of life, and are popularly known by the name of trades and manufactures. Such are weaving, turnery, brewing, masonry, clock-making, carpentry, joinery, foundry, printing, &c. These arts, which indeed are innumerable, were formerly comprised in this verse.

Rus, Nemus, Arma, Faber, Vulnera, Lana, Rates.

They take their denomination from *μηχανη*, machine, as being all practised by means of some machine or instrument. With the liberal arts it is otherwise; there being several of them which may be learnt and practised without any

instrument at all; as logic, eloquence, medicine, properly so called, &c.

Lord Bacon has observed that the arts which relate to the sight and hearing are reputed liberal, beyond those which regard the other senses, and are chiefly employed in matters of luxury; these are usually called the fine arts; such are poetry, painting, sculpture, music, gardening, and architecture.

As all arts have this common property according to Mr. Harris, that they respect human life, it is evident that some contribute to its necessities, as medicine and agriculture; and others to its elegance, as music, painting, and poetry. The former seem to have been prior in time to the latter. Men must naturally have consulted how to live and to support themselves, before they began to deliberate how to render life agreeable. Indeed this is confirmed by fact; as no nation has been known so barbarous and ignorant as not in some degree to have cultivated the rudiments of these necessary arts; and hence possibly they may appear to be more excellent and worthy, as having claim to a preference derived from their seniority. The arts, however, of elegance are not destitute of pretensions, if it be true that nature formed us for something more than mere existence. Nay farther, if well-being be clearly preferable to mere being, and this, without the other, be contemptible, they may have reason perhaps to aspire even to a superiority. *Harris, ubi supra, p. 54.*

The history of the origin and progress of particular arts is recited under their respective denominations in the course of this work. It may be here observed however, in general, that most of the arts that are necessary to the subsistence, or conducive to the convenience and comfort of mankind, have had a very early origin.

Some useful arts must be nearly coeval with the human race; for food, clothing, and habitation, even in their original simplicity, require some art. Many others are of such antiquity as to place the inventors beyond the reach of tradition. Several have gradually crept into existence without any recorded inventor or history. The busy mind, however, accustomed to a beginning in all things, cannot rest till it finds or imagines a beginning to every art.

It has been generally admitted that the arts had their rise in the East, and that they were conveyed from thence to the Greeks, and from them to the Romans. The Romans, indeed, seem to have been chiefly indebted to the Greeks, by whom they were excelled in point of invention. The Romans acknowledged this superiority, for they sent their youth to Greece in order to finish their education; and from this circumstance we may infer, that they considered that country as the seat of the arts and sciences, and as a school where genius would be excited by the most finished models, and the taste corrected and formed. Pliny and other writers have, nevertheless, given hints which lead us to believe that the Romans possessed a more extensive knowledge of the arts than modern writers are sometimes willing to allow; and that several inventions regarded as recent are only old ones revived and again applied to practice. The dark ages at once

extinguished the knowledge of the past, and retarded the revival of art; yet it cannot be denied, that several important discoveries altogether unknown to the ancients were made in those ages. Of this kind were the inventions of paper, painting in oil, the mariner's compass, gunpowder, printing, and engraving on copper: see the several articles. After the invention of the compass and printing, two grand sources were opened for the improvement of science. As navigation was extended, new objects were discovered to awaken the curiosity and excite the attention of the learned; and the ready means of diffusing knowledge afforded by the press, enabled the ingenious to make them publicly known. Ignorance and superstition, the formidable enemies of philosophy in every age, began to lose some of that power which they had usurped, and different states, forgetting their former blind policy, adopted improvements which their prejudices had before condemned.

In countries, however, where civil and ecclesiastical tyranny prevailed, the progress of the useful and elegant arts was slow, and struggled with many difficulties. Particular events, indeed, have occurred in all ages and nations which have roused the exertions of genius, and furnished occasion for making important and useful discoveries. The history of Greece and Rome, and even of modern Europe, will afford many obvious facts that confirm and illustrate this observation. We can add but a few other miscellaneous ones.

In different countries the progress of the same arts has been extremely different. Though the compass was used in China for navigation long before it was known in Europe, yet to this day, instead of suspending it in order to make it act freely, it is placed upon a bed of sand, by which every motion of the ship disturbs its operation. Water-mills for grinding corn are described by Vitruvius, and wind-mills were known in Greece and in Arabia as early as the seventh century; yet no mention is made of them in Italy till the fourteenth; and that they were not known in England in the reign of Henry VIII. appears from a household book of the Northumberland family, stating an allowance for three mill-horses, 'two to draw in the mill, and one to carry stuff to the mill and fro.' Water-mills for corn must in England have been of a late date. The ancients had mirror-glasses, and employed glass to imitate crystal vases and goblets; yet they never thought of using it in windows. In the thirteenth century, the Venetians were the only people who had the art of making crystal glass for mirrors. A clock that strikes the hours was unknown in Europe till the end of the twelfth century. And hence the custom of employing men to proclaim the hours during night; which to this day continues in Germany, Flanders, and England. Galileo was the first who conceived an idea that a pendulum might be useful for measuring time; and Huygens was the first who put the idea in execution, by making a pendulum clock. Hook, in 1660, invented a spiral spring for a watch, though a watch was far from being a new invention. Paper was made no earlier than the fourteenth century; and the invention of printing was a century later. Silk manufactures were

long established in Greece before silk-worms were introduced there. The manufacturers were provided with raw silk from Persia: but that commerce being frequently interrupted by war, two monks, in the reign of Justinian, brought eggs of the silk-worm from Hindostan, and taught their countrymen the method of managing them.—The art of reading made a very slow progress. To encourage that art in England, the capital punishment for murder was remitted, if the criminal could but read, which in law language is termed benefit of clergy. One would imagine that the art must have made a very rapid progress when so greatly favored: but there is a signal proof of the contrary; for so small an edition of the Bible as 600 copies, translated into English in the reign of Henry VIII. was not wholly sold off in three years. And the people of England must have been profoundly ignorant in Queen Elizabeth's time, when a forged clause added to the twentieth article of the established creed passed unnoticed till about a century ago.

The circumstances which arouse the national spirit upon any particular art, promote activity to prosecute other arts. When the Romans came to excel in the art of war, they rapidly improved in other arts. Nævius composed in verse seven books of the Punic war; besides comedies, replete with bitter raillery against the nobility. Ennius wrote annals, and an epic poem; and Lucius Andronicus became the father of dramatic poetry in Rome. And the Roman genius for the fine arts was much inflamed by Greek learning when free intercourse between the two nations was opened.

The progress of art seldom fails to be rapid, when a people happen to be roused out of a torpid state by some fortunate change of circumstances: public liberty now gives to the mind a spring which is vigorously exerted in every new pursuit. The Athenians made but a mean figure under the tyranny of Pisistratus; but, upon regaining their freedom and independence, arts flourished with arms, and Athens became the chief theatre for science as well as for the fine arts. The reign of Augustus Cæsar, which put an end to the rancor of civil war, and restored peace to Rome with the comforts of society, proved an auspicious era for literature; and produced a cluster of Latin historians, poets, and philosophers, to whom the moderns are indebted for their taste. A similar revolution happened in Tuscany about 350 years ago. That country having been divided into a number of small republics, the people excited by mutual petty quarrels, became ferocious and bloody, flaming with revenge for the slightest offence. But being united under the Great Duke of Tuscany, these republics enjoyed the sweets of peace and a mild government; when the retrospect of recent calamities roused the national spirit, and produced ardent application to arts and literature. The restoration in England in 1660, which put an end to an envenomed civil war, promoted improvements of every kind, and arts and industry made a rapid progress. Had the nation, upon that favorable turn of fortune, been blessed with a succession of able and virtuous princes, arts and sciences might much earlier have flourished

in their modern perfection. Some important action even of doubtful event, a struggle for liberty, the resisting a potent invader, or the like, have also had beneficial influences on the progress of art. Greece, divided into small states frequently at war with each other, advanced in literature and the fine arts to unrivalled perfection. The Corsicans, while engaged in a perilous war in defence of their liberties, exerted a vigorous national spirit; they founded a university for arts and sciences, a public library, and a public bank. After a long stupor during the dark ages of ecclesiastical tyranny, arts and literature revived among the turbulent states of Italy. The Royal Society in London, and the Academy of Sciences in Paris were both instituted after prolonged civil wars that had animated the people and roused their activity. On the other hand, as the progress of arts and sciences towards perfection is greatly promoted by emulation, nothing is sometimes more fatal than to remove this spur; as when some extraordinary genius appears to soar above rivalship. Thus mathematics long seemed to be declining in Britain: the great Newton, having surpassed all the ancients, left the moderns without any hope of equalling him; for what man will enter the lists who despairs of victory?

The useful have in all ages paved the way for the fine arts. Men upon whom the former had bestowed every convenience turned their thoughts to the latter. Beauty was studied in objects of sight; and men of taste attached themselves to the fine arts, which multiplied their enjoyments and improved their benevolence. Sculpture and painting made an early figure in Greece; which afforded plenty of beautiful originals to be copied in these imitative arts. Statuary, a more simple imitation than painting, was sooner brought to perfection: the statue of Jupiter by Phidias, and of Juno by Polycletes, though the admiration of all the world, were executed long before the art of light and shade was known. Another cause concurred to advance statuary before painting in Greece, viz. a great demand for statues of their gods. Architecture, as a fine art, made a slower progress. Proportions upon which its elegance chiefly depends, cannot be accurately ascertained, but by an infinity of trials in great buildings; a model cannot be relied on: for a large and small building, even of the same form, require different proportions. Literature as a branch of the fine arts deserves a separate consideration. See LITERATURE.

The cause of the decline of the fine arts may be illustrated by various instances. The perfection of vocal music is to accompany passion, and to enforce sentiment. In ancient Greece, the province of music was well understood; and being confined within its proper sphere, it had an enchanting influence. Harmony at that time was very little cultivated, because it was of very little use; melody reaches the heart, and it is by it chiefly that a sentiment is enforced, or a passion soothed: harmony, on the contrary, reaches the ear only; and it is a matter of undoubted experience, that the melodious airs admit but of very simple harmony. Artists, in later times, ignorant why harmony was so little regarded by

the ancients, applied themselves seriously to its cultivation, and have been wonderfully successful. But successful at the expense of melody; which, in modern compositions, generally speaking, is lost amid the blaze of harmony. In the Italian opera, the mistress is degraded to be handmaid; and harmony triumphs, with very little regard to sentiment. Among the Greeks also, as a conquered people, the fine arts decayed; but not so rapidly as at Rome under her various despotic emperors; the Greeks farther removed from the seat of government, being less within the reach of the Roman tyrants. During their depression they were guilty of the most puerile conceits; witness verses composed in the form of an axe, an egg, wings, and such like. The style of Greek authors, in the reign of Adrian, is unequal, obscure, stiff, and affected. Lucian is the only exception. We need scarce any other cause but despotism, to account for the decline of statuary and painting in Greece. These arts had arrived at their utmost perfection about the time of Alexander the Great; and from that time they declined gradually with the vigor of a free people; for Greece was now enslaved by the Macedonian power. It may in general be observed, that when a nation becomes stationary in that degree of power which it acquires from its constitution and situation, the national spirit subsides, and men of talents become rare. It is still worse with a nation that is sunk below its former power and pre-eminence; and worst of all, when it is reduced to slavery. Other causes concur to accelerate the downfall of the arts mentioned. Greece, in the days of Alexander, was filled with statues of excellent workmanship; and there being little demand for more, the later statuary were reduced to make heads and busts. At last the Romans put a total end, both to statuary and painting in Greece, by plundering it of its finest pieces: and the Greeks, exposed to the avarice of the conquerors, bestowed no longer any money on the fine arts. The decline of the fine arts in Rome is, by Petronius Arbitrator, a writer of taste and elegance, ascribed to a cause different from any above mentioned, i. e. opulence, with its faithful attendants avarice and luxury. In England the fine arts are far from such perfection as to suffer by opulence. They are in a progress, indeed, towards maturity; but proceed at a very slow pace. Another cause that never fails to undermine a fine art in a country where it is brought to perfection, abstracting from every one of the causes above mentioned, has been already pointed out. Nothing is more fatal to an art or science, than performances so much superior to all of the kind as to extinguish emulation. This cause would have been fatal to the arts of statuary and painting among the Greeks, even though they had continued a free people. The decay of painting in modern Italy is probably owing to this cause: Michael Angelo, Raphael, Titian, &c. are lofty oaks, that bear down young plants in their neighbourhood, and intercept them from the sunshine of emulation. Had the art of painting made a slower progress in Italy, it might have there continued in vigor to this day. Archi-

ecture continued longer in vigor than painting, because the principles of comparison in the former art were less precise than in the latter. The artist who could not rival his predecessors in an established mode, sought out a new mode for himself, which, though perhaps less elegant or perfect, was for a time supported by novelty. Useful arts will never be neglected in a country where there is any police; for every man finds his account in them. Fine arts are more precarious. They are not relished but by persons of taste, who are rare; and such as can spare great sums for supporting them, who are still more rare. For that reason they will never flourish in any country, unless patronised by the sovereign, or by men of power and opulence. And richly do they merit such patronage, as one of the springs of government; multiplying amusements, and humanising manners.

ART, the second person singular of the verb **TO BE**, of which the English language affords no variation, except by adopting the plural, by saying **You are**, instead of **Thou art**. **Thou beest** indeed was anciently used, but it is quite obsolete.

ART and **PART** in Scots law. See **ACCESSARY**.

ARTA, or **LARTA**, a gulf, river, and town of European Turkey, in Albania, or Epirus, belonging to the government of Romania. The town is seated on the river of the same name, nine miles north of the spot where it falls into the gulf of Arta, above twenty miles north-east of Prevesa, and about 360 W. N. W. of Constantinople. The number of inhabitants, Christians as well as Turks, amounts to six thousand, who trade in cattle, wine, tobacco, cotton, flax, pulse, fur, leather, and other commodities. They also manufacture coarse woollen and other cloths. It is the seat of a Greek metropolitan and several European consuls. The gulf, otherwise called the gulf of Prevesa, extends a considerable way inland in an eastern direction, and from its rocks and sand banks, is very dangerous. Long. 21° 8' E., lat. 39° 30' N.

ARTABA, an ancient measure of capacity used by the Persians, Medes, and Egyptians.—The Persian artaba is represented by Herodotus as bigger than the Attic medimnus by three Attic chœnixes; from which it appears that it was equal to 6½ Roman modii; consequently that it contained 166½ pounds of wine or water, or 126½ pounds of wheat. The Egyptian artaba contained five Roman modii, and fell short of the Attic medimnus by one modius; consequently held 133½ pounds of water or wine, 100 lb. of wheat, or sixty of flour.

ARTABANUS, the name of several kings of Parthia. See **PARTHIA**.

ARTABANUS, the brother of Darius I. and the uncle and murderer of Xerxes. See **ARTAXERXES**.

ARTABAZUS, the son of Pharnaces, commanded the Parthians and Chorasmians in the famous expedition of Xerxes. After the battle of Salamis, he escorted the king his master to the Hellespont with 60,000 chosen men; and after the battle of Plataea, in which Mardonius engaged contrary to his advice, he made a noble retreat, and returned to Asia with 40,000 men.

ARTAKI, a town of Asiatic Turkey, in Na-

tolia, on the south coast of the sea of Marmora, forty-five miles east of Gallipoli and ninety south-west of Constantinople. Long, 27° 39' E., lat. 40° 18' N.

ARTAKUI, a town of European Turkey, in Romania, forty-eight miles north-west of Gallipoli.

ARTALIS (Joseph), a native of Mazara, A. D. 1628, who showed an early inclination both for poetry and arms. He finished his studies at fifteen years of age, when he fought a duel and killed his adversary. He took shelter in a church and afterwards studied philosophy. Candia being besieged by the Turks, he went to its relief, and displayed so much valor that he was created a knight of St. George. Being afterwards engaged in several encounters and always victorious, he got the title of Chevalier de Sang, or the knight of blood. His literary talents obtained him the honor of being elected a member of several academies in Italy, and his military abilities procured him the favor of several princes, particularly of the Emperor Leopold I. and Ernest duke of Brunswick.

ARTAXATA, an ancient city, the metropolis of Armenia Major, and the residence of the Armenian kings: it was built according to a plan of Hannibal, for king Artaxias; and was situated on a branch of the river Araxes, which formed a kind of peninsula, and surrounded the town like a wall, except on the side of the isthmus, but this side was secured by a rampart and ditch. The town was deemed so strong that Lucullus, after having defeated Tigranes, durst not lay siege to it; but Pompey compelled him to deliver it without striking a blow. It was then levelled with the ground; but the Armenians have a tradition, that the ruins of it are still to be seen at a place called Ardachat. Sir John Chardin says, that it has the name of Ardachat, from Artaxias, whom in the east they call Ardechier. Here are the remains of a stately palace, which the Armenians take to be that of Tiridates, who reigned in the time of Constantine. One front of this building is half ruined, and there are many other fine antiquities.

ARTAXATA, or **ATROPATIA**, another city built also on the Araxes, in the northern part of Media.

ARTAXERXES I. king of Persia, surnamed Longimanus, from the uncommon length of his arms, was the youngest son of Xerxes, and was raised to the throne A. M. 3487, by Artabanus, the captain of the guards, who had privately murdered his father; but persuaded the young prince that his elder brother Darius had done it; whereupon, assisted by the guards, he killed Darius in his bed-chamber. But the murder and treason being afterwards discovered, Artabanus suffered the punishment he merited. Some reckon this king the Ahasuerus who married Esther; but, be that as it may, it is certain that he greatly favored the Jews, by not only authorising them to return to Judea, and rebuild Jerusalem, but also to collect money for the use of their temple; as well as by remitting their tribute, by encouraging their worship, and by making them a number of valuable presents, &c. See his letter to Ezra, chapter vii, 10—26. For

an account of the other transactions of his reign, see **PERSIA**. He reigned about forty years, and died A. A. C. 447.

ARTAXERXES II. surnamed Mnemon, from his great memory, succeeded his father Darius II. A. M. 3546, but had to contend for his kingdom with his younger brother Cyrus, who was assisted by the Greeks, but was at last overcome and slain. It was after this battle that Xenophon displayed his generalship by his memorable retreat with his army. Artaxerxes reigned forty-three years, and died A. M. 3589. See **PERSIA**.

ARTAXERXES is also the name given in Scripture to, and probably assumed by, the impostor Oropastes; who, pretending to be Smerdis the son of Cyrus, reigned five months in Persia, after the death of Cambyses. During his short reign, the enemies of the Jews applied for, and obtained, an interdict of the rebuilding of the city and temple. See Ezra iv. 7.

ARTAXIAS, the founder of the kingdom of Armenia Major. See **ARMENIA** and **ARTAXATA**.

ARTEDI (Peter), a famous Swedish naturalist, born in 1705. He was educated at the university of Upsal, where he studied medicine; but his time was chiefly dedicated to ichthyology, in which he made many valuable discoveries.—Such was the friendship between him and Linnæus, that the longest liver was to be heir of all their MSS. He was drowned at Leyden in 1735. His *Bibliotheca Ichthyologica* and *Philosophia Ichthyologica*, were published by Linnæus in 1738.

ARTEDIA, in botany, a genus of the digynia order, and pentandria class of plants; ranking in the natural method, under the forty-fifth order, umbellatæ. The involucre are pinnatifid; the floscules of the disc are masculine; and the fruit is hispid with scales. The principal species is, viz. *A. squamata*, with squamose seeds, a native of the east. Rauwolf found it growing on mount Libanus. It is an annual plant, whose stalks rise about two feet high, sending out a few side branches, garnished with narrow compound leaves resembling those of dill.

ARTEMIDORUS, a Grecian teacher in Rome, who being intimate with Brutus, and learning from him of the intended assassination of Cæsar, delivered a note to him to inform him of it, as he went to the senate-house, and desired him to read it immediately, which Cæsar neglecting, fell a sacrifice to the plot.

ARTEMIDORUS, an ancient author, under Antoninus Pius, famous for his Treatise on Dreams, which was first printed in Greece at Venice in 1518. Rigaltius published an edition at Paris in Greek and Latin in 1603, and added some notes. Artemidorus wrote also treatises upon Auguries and Chiromancy; which are not extant.

ARTEMISIA I. queen of Caria, and the daughter of Ligdamis, marched in person in the expedition of Xerxes against the Greeks, and performed wonders in the sea-fight near Salamis, A. A. C. 480. Being pursued by an Athenian vessel, she attacked one of the Persian ships, commanded by the king of Calyndus, and sunk it; on which the Athenians, thinking that her ship was on the side of the Greeks, ceased their pursuit; but Xerxes was the principal person

imposed upon in this affair; for believing that she had sunk an Athenian vessel, he declared that 'the men had behaved like women, and the women like men.' Xerxes entrusted her with the care of the young princes of Persia, his sons, when, agreeably to her advice, he abandoned Greece in order to return to Persia. These great qualities did not secure her from the weakness of love; she was passionately fond of a man of Abydos, whose name was Dardanus, and was so enraged at his neglect of her, that she put out his eyes while he was asleep. Having consulted the Delphian Oracle how to extinguish this passion, and being advised to go to Leucas, which was the usage of desperate lovers, she took the leap from thence, and was drowned, and interred at that place. Many writers confound this princess with the wife of Mausolus.

ARTEMISIA II., queen of Caria, the widow of king Mausolus, has immortalised herself by the honors which she paid to the memory of her husband. She built for him, in Halicarnassus, a very magnificent tomb, called the Mausoleum, which was one of the seven wonders of the world, and from which the title of mausoleum was afterwards given to all tombs remarkable for their grandeur, but died of grief before the mausoleum was finished. She is said to have drank his ashes; and to have offered a prize of great value to the person who should compose the best eulogium on his memory. He died about the end of the 106th Olympiad. A. A. C. 351.

ARTEMISIA, mugwort, southernwood, and wormwood; a genus of the polygamia superflua order, and syngenesia class of plants, ranking in the natural method under the forty-ninth order, compositæ nucamentacæ. The receptacle is either naked or a little downy; it has no pappus; the calyx is imbricated with roundish scales; and the corolla has no radii. There are twenty-three species, of which the following are the most remarkable: viz.

1. *A. abrotanum*, or southernwood, which is kept in gardens for the sake of its agreeable scent, a low shrub, seldom rising more than three or four feet high. 2. *A. absinthium*, or common wormwood, grows naturally in lanes and uncultivated places, and is too well known to require any description. 3. *A. arborescens*, or tree-wormwood, grows naturally in Italy and the Levant, near the sea. It rises with a woody stalk, six or seven feet high, sending out many ligneous branches, garnished with leaves somewhat like those of the common wormwood, but more finely divided and much whiter. 4. *A. dracunculus*, or Tarragon, is frequently used in salads, especially by the French, and is a very hardy plant, spreading greatly by its creeping roots. 5. *A. maritima*, or sea-wormwood, grows naturally on the sea-coast in most parts of Britain, where there are several varieties to be found. 6. *A. Pontica*, or Pontic wormwood, commonly called Roman wormwood, is a low herbaceous plant whose stalks die in autumn, and new ones rise up in the spring. The flowers appear in August, but are rarely succeeded by seeds in Britain. 7. *A. santonicum*, produces the semen santonicum, which is much used for worms in children. It grows naturally in

Persia, from whence the seeds are brought to Europe. 9. *A. vulgaris*, or common mugwort, grows naturally on banks and by the sides of foot-paths in many parts of Britain: in gardens it proves a troublesome weed. The seeds of the santonicum are small, light, chaffy, composed as it were of a number of thin membranous coats of a yellowish color, an unpleasant smell, and a very bitter taste. They are celebrated for antelmintic virtues, which they have in common with other bitters, and are sometimes taken with this intention, either along with molasses or candied with sugar. They are not often met with genuine in the shops. The leaves of the sea, common, and Roman wormwoods are used as stomachics, but are all very disagreeable: the Roman is the least so and therefore is to be preferred; but the other two kinds are generally substituted in its place. The distilled oil of wormwood is sometimes made use of externally as a cure for worms. The leaves of the vulgaris or common mugwort were commonly celebrated as uterine and antihysterical: an infusion of them is sometimes taken, either alone or in conjunction with other substances, in suppression of the menstrual evacuations. In some parts of this kingdom mugwort is of common use as a pot-herb. It is now, however, very little employed in medicine; and it is probably with propriety that the London college have rejected it from the Pharmacopœia.

The moxa, so famous in the eastern countries for curing the gout, by burning it on the part affected, is the lanugo or down growing on the under side of the leaves of a species of mugwort, supposed to be the same with our common sort. From some dried samples of this plant which were brought over to this country, Mr. Miller reckons them to be the same, differing only in size. He supposes that the lanugo of our mugwort would be equally efficacious. The abbe Crosier says the ancient Chinese made great use of it in medicine.

ARTEMISIA, yearly festivals anciently observed in divers cities in Greece, particularly Delphi, in honor of Diana Artemis. In the artemisia a mullet was sacrificed to this goddess, as being thought to bear some resemblance to her, because it is said to hunt and kill the sea-hare.

ARTEMISIUM, a promontory on the north-east of Eubœa, (called Leon and Cale Acte by Ptolemy,) memorable for the first sea engagements between the Greeks and Xerxes, of which the following account is given by Gillies: 'The Grecian fleet was stationed in the harbour, while that of the Persians, too numerous for any harbour to contain, had anchored between the city of Castanea and the promontory of Sepias, on the coast of Thessaly. The first line of their fleet was sheltered by the coast of Thessaly; but the other lines, to the number of seven, rode at anchor, at small intervals, with the prows of the vessels turned to the sea. When they adopted this arrangement the waters were smooth, the sky clear, the weather calm and serene; but on the morning of the second day after their arrival on the coast, the sky began to lower, the appearance of the heavens grew threatening and terrible; a dreadful storm succeeded; raged for three days

with unabating fury, and destroyed 400 galleys, besides a vast number of store-ships and transports. However, 800 ships of war, besides innumerable vessels of burden, sailed into the Pega-sean bay and anchored in the road of Aphete, directly opposite to the harbour of Artemisium. The Grecians had posted sentinels on the heights of Eubœa, to observe the consequences of the storm, and to watch the motions of the enemy. When informed of the disaster which had befallen them they poured out a joyful libation, and sacrificed, with pious gratitude, to 'Neptune the Deliverer.' The Persians, however, having recovered from the terrors of the storm, prepared for battle; and, as they entertained not the smallest doubt of conquering, they detached 200 of their best sailing vessels round the isle of Eubœa, to intercept the expected flight of the enemy through the narrow Euripus. About sunset the Grecian fleet approached in a line, and the Persians met them with the confidence of victory, as their ships were still sufficiently numerous to surround those of their opponents. At their first signal the Greeks formed into a circle, at the second they began the fight. Though crowded into a narrow compass, and having the enemy on every side, they soon took thirty of their ships, and sunk many more. Night came on, accompanied with an impetuous storm of rain and thunder; the Greeks retired into the harbour of Artemisium; the enemy were driven to the coast of Thessaly. By good fortune however, rather than by design, the greatest part of the Persian fleet escaped immediate destruction, and gained the Pega-sean bay; but the ships ordered to sail round Eubœa met with a more dreadful disaster. They were overtaken by the storm, after they had ventured farther from the shore than was usual with the wary mariners of antiquity. Clouds soon intercepted the stars, by which alone they directed their course; and after continuing during the greatest part of the night the sport of the elements, they all perished miserably amidst the shoals and rocks of an unknown coast. The morning arose with different prospects and hopes to the Persians and Greeks. To the former it discovered the extent of their misfortunes; to the latter it brought a reinforcement of fifty-three Athenian ships. Encouraged by this favorable circumstance, they determined again to attack the enemy at the same hour as on the preceding day, because their knowledge of the coast, and their skill in fighting their ships, rendered the dusk peculiarly propitious to their designs. At the appointed time they sailed towards the road of Aphete; and having cut off the Cilician squadron from the rest, totally destroyed it, and returned at night to Artemisium. The Persian commanders being deeply affected with the repeated disasters, but still more alarmed at the much dreaded resentment of their King, determined to make one vigorous effort for restoring the glory of their arms. By art and stratagem, and under favor of the night, the Greeks had hitherto gained many important advantages. It now belonged to the Persians to choose the time for action. On the third day, at noon, they sailed forth in the form of a crescent, still sufficiently extensive to unfold the Grecian

line. The Greeks, animated by former success were averse to decline any offer of battle; yet it is probable that their admirals, and particularly Themistocles, would much rather have delayed it to a more favorable opportunity. Rage and resentment supplied the defect of the barbarians in skill and courage. The battle was longer, and more doubtful, than on any former occasion; many Grecian vessels were destroyed, five were taken by the Egyptians, who particularly signalised themselves on the side of the barbarians, as the Athenians did on that of the Greeks. The persevering valor of the latter at length prevailed, the enemy retiring, and acknowledging their superiority, by leaving them in possession of the dead and the wreck. But the victory cost them dear; since their vessels, particularly those of the Athenians, were reduced to a very shattered condition; and their great inferiority in the number and size of their ships made them feel more sensibly every diminution of strength.

ARTEMISIUM, a town of Enotria, now called St. Agatha, in Calabria, on the river Pisaurus, or la Foglia, eight miles distant from the Tuscan sea.

ARTEMISIUM, an ancient town of Spain, on the sea-coast of Valencia, called also Dianium, and now Denia, possessed by the Contestani.

ARTEMON, a Syrian who resembled Antiochus, king of Syria, so exactly, that by the contrivance of his queen Laodice, he personated him after his death, and thus obtained the kingdom.

ARTEMON, the founder of the sect of Artemonites, a sect of Unitarians who flourished about the year 210.

ARTEMUS, a promontory of Valencia, called also Cabo St. Martin, and Punta del' Emperador.

ARTEENNA, in ornithology, the name of a water-bird, of the size of a hen, of a brownish color on the back, and white on the belly; having a crooked bill, and its three fore toes connected by a membrane, but the hinder one loose. It is found on the island Tremeiti, in the Adriatic sea, and is supposed to be the avis Diomedis of the ancients.

ARTERIA ASPERA, **ARTERIA BRONCHIALIS**, &c. See **ANATOMY**, Index.

ARTERIA VENOSA, a name given by the ancients to the pulmonary vein, on the erroneous supposition of its being an air-vessel, and that it served for the conveyance of the vital aura from the lungs to the heart.

ARTERIACA, **ARTERIACS**. Medicines for disorders of the trachea, and the voice. Arteriacs are reduced by Galen into three kinds: 1. Such as are void of acrimony, serving to mollify the asperities of the part; such as gum tragacanth, aster samias, starch, milk, &c. 2. Those of an acrimonious quality, whereby they stimulate even the sound parts; such as honey, turpentine, bitter almonds, iris root, &c. 3. Those of an intermediate kind, soft and mild, yet detergent; such as butter, and preparations of almonds, honey, &c.

ARTERIOSA VENA, or **ARTERIAL VEIN**, a denomination given to the pulmonary artery.

ARTERIOSUS CANALIS, a tube in the heart of the fœtus, which, with the foramen ovale, serves to maintain the circulation of the blood, and to divert it from the lungs.

ARTERY, ὁ Ἀρτηρία, *spiritus semita*, accord-
ARTERIAL. § *ing* to Pliny and Cicero. The
 moderns have a more accurate knowledge of the
 human body than this bare and inadequate de-
 finition of the ancients affords. See **ANATOMY** for
 a complete view of the arteries.

Universal plodding prisons up

The nimble spirits in the arteries.

Shakespeare. Love's Labour Lost.

Had not the Maker wrought the springy frame ;

The blood, defrauded of its nitrous food,

Had cool'd and languish'd in the arterial road.

Blackmore.

As this mixture of blood and chyle passeth through
 the *arterial tube*, it is pressed by two contrary forces ;
 that of the heart driving it forward against the sides
 of the tube ; and the elastic force of the air, pressing it
 on the opposite sides of those air-bladders, along
 the surface of which this *arterial tube* creeps.

Arbuthnot.

ARTHEL, in law, something cast into a court,
 in Wales, or its marches, whereby the court is
 letted or discontinued for the time. The casting
 of arthel is prohibited, 26 Hen. VIII. cap. 6.

ARTHINGTON (Henry), a fanatical gentle-
 man of Yorkshire, who, towards the end of queen
 Elizabeth's reign, engaged in treasonable prac-
 tices against the government, with Edward Cop-
 pinger a servant of the queen's, and one Hacket,
 whom, in their fanaticism they styled 'king of
 Europe.' Supposing themselves to be inspired,
 Coppinger styled himself the 'prophet of mercy,'
 and Arthington the 'prophet of judgment.'
 Arthington accordingly wrote and published his
 prophecies, wherein were intermingled some se-
 vere reflections against the lords of the privy
 council, the judges, &c. They were at last all
 three apprehended in July, 1591 ; when Cop-
 pinger became quite deranged, and never re-
 covered his senses. Hacket was tried, con-
 demned, and executed ; and Arthington hearing
 of this, wrote a submissive letter to the lords of
 council, which, after some time, procured him
 the queen's pardon. He died with the character
 of an honest but weak man.

ARTHRITICA, in botany, a name given by
 some to the primrose, and by others to the ground
 pine.

ARTHRITICAL, ὁ Ἀρθριτικὸς, pain or disease

ARTHRITICK. § which attacks the joints,
 from ἄρθρον, a joint.

Frequent changes produce all the *arthritick* diseases.

Arbuthnot.

Serpents, worms, and leaches, though some want
 bones, and all extended articulations, yet have they
arthritical analogies ; and, by the motion of fibrous and
 muscular parts, are able to make progression.

Brown's Vulgar Errors.

Unhappy! whom to beds of pain

Arthritic tyranny consigns ;

Whom smiling nature courts in vain,

Though rapture sings and beauty shines.

Johnson's Ode on Spring.

ARTHRITIS ; from ἄρθρον, a joint ; any
 disorder that affects the joints, but the gout
 particularly.

ARTHRITIS PLANTICA, **ARTHRITIS VAGA**, the
 wandering gout, that gives pain sometimes in
 one limb, and sometimes in another.

ARTHRODIA, in anatomy, a species of ar-
 ticulation, wherein the flat head of one bone is

received into a shallow socket in the other. The
 humerus and scapula are joined by this species
 of articulation. See **ANATOMY**, Index.

ARTHRODIA, in natural history, a genus of
 imperfect crystals, found always in complex
 masses, and forming long single pyramids, with
 very short and slender columns.

ARTHRODIA, in zoology, a class of animalculæ,
 containing those with visible limbs.

ARTHRON ; ἄρθρον, Greek ; a joint, or
 connection of bones proper for motion.

ARTHIROSIS, in anatomy, a juncture of two
 bones designed for motion ; called also articu-
 lation. See **ARTHRODIA**.

ARTHUR, the celebrated hero of the Britons,
 is said to have been the son of Uter, named Pen-
 dragon, king of Britain, and to have been born
 in 501. His life is a continued scene of won-
 ders. He killed 470 Saxons with his own hand
 in one day ; and after having subdued many mighty
 nations, and instituted the order of the knights
 of the Round Table, died A. D. 542, of wounds
 which he received in battle. The most par-
 ticular detail of his story and his exploits is that
 given by Geoffrey of Monmouth ; but his history
 is so blended with the marvellous and the extra-
 vagant, that not only the truth of the whole, but
 even the reality of Arthur's existencé, has been
 called in question. The ingenious Mr. Whitaker
 however believes in his institution of the cele-
 brated order of the round table, as also that it
 was the origin of others of the like kind on the
 continent.

ARTHUR'S SEAT, a high hill in the neigh-
 bourhood of Edinburgh, said to have been so
 denominated from a tradition that king Arthur
 surveyed the country from its summit, and had
 also defeated the Saxons in its neighbourhood.
 This hill rises by a steep and rugged ascent, till it
 terminates in a rocky point near 700 feet from
 the base, being more than double the height of the
 cross on the top of St. Paul's, London, which is
 340 feet. On the south it is in many parts a perpen-
 dicular rock, composed of basaltic pillars, regu-
 larly pentagonal or hexagonal, about three feet in
 diameter, and from forty to fifty feet in height.
 Contiguous upon the west, and partly connected
 with it at the base, are Salisbury crags, of infe-
 rior height but exhibiting an appearance equally
 singular and grand. They present to the city an
 awful front of broken rocks and precipices, form-
 ing a sort of natural amphitheatre of solid rock ;
 and backward from the craggy verge above, the
 hill forms an extensive irregular slope, the surface
 affording pasture to numerous flocks of sheep.
 The crags, beside ores, spars, rock-plants, and
 here and there it is said some precious stones, af-
 ford an inexhaustible supply of granite for paving
 the streets, &c. In quarrying a part of the crags
 has been worn down into a spacious shelf, having
 the appearance of a lofty terrace, and stretching
 a considerable length. From hence is a near and
 distinct prospect of the city with its environs and
 the adjacent country. But from the pinnacle
 called Arthur's Seat the view is more noble and
 extensive. The traveller may here sit and survey
 at his ease the centre of the kingdom, besides hav-
 ing a complete view of Edinburgh and its castle,
 on which he looks down as if seated among the

clouds. In a word, the German ocean, the whole course of the Forth, the distant Grampians, and a large portion of the most populous and best cultivated part of Scotland, form a landscape sublime, various and beautiful. The denomination of this hill, derived as above, has been adduced as an argument against those who dispute the existence of the British Arthur. That derivation, however, though probable, is not without uncertainty. For Arthur's Seat is said to be derived, or rather corrupted, from A'rd Seir, 'a place or field of arrows,' where people shot at a mark: and this not improbably; for among these cliffs is a dell or recluse valley, where the wind can scarcely reach, now called the Hunter's bog, the bottom of it being a morass. The adjacent craggs are supposed to have taken their name from the earl of Salisbury, who, in the reign of Edward III. accompanied that prince in an expedition against the Scots; though, according to others, the genuine derivation, like that of Arthur's seat, is from a Celtic word also corrupted.

ARTICHOKE, in botany. See CINARA.

ARTICLE, *v.* & *n.*

ARTICULATE, *v.* & *adj.* } Lat. *articulus*, a di-
 ARTICULATEDLY, } minutive of *artus*, a
 ARTICULATION, } joint. To enter into,
 draw up or state particu-
 lars, to make terms. To articulate is to pro-
 nounce each portion of a sentence distinctly.

PROSPERO. Hast thou, spirit,

Performed to point the tempest that I had thee.

ARIEL. To every *article*. *Shakspeare. Tempest.*

Henry's instructions were extreme curious and *articulate*, and in them more articles touching inquisition, than negotiation; requiring an answer in distinct articles to his questions. *Bacon.*

In speaking under water, when the voice is reduced to an extreme exility, yet the *articulate* sounds, the words, are not confounded. *Id.*

The first, at least, of these I thought deny'd
 To beasts; whom God, on their creation day,
 Created mute to all *articulate* sound. *Milton.*

Antiquity expressed numbers by the fingers on either hand. On the left they accounted their digits and *articulate* numbers unto an hundred; on the right hand, hundreds and thousands.

Brown's Vulgar Errors.

If it be said, God chose the successor, that is manifestly not so in the story of Jephtha, where he *articled* with the people, and they made him judge over them.

Locke.

By *articulation* I mean a peculiar motion and figure of some parts belonging to the mouth, between the throat and lips. *Holder.*

All the precepts, promises, and threatenings of the gospel, will rise up in judgment against us; and the *articles* of our faith will be so many *articles* of accusation; and the great weight of our charge will be this, That we did not obey the gospel, which we professed to believe; that we made confession of the Christian faith, but lived like Heathens. *Tillotson.*

You have small reason to repine upon that *article* of life. *Swift.*

The dogmatist knows not by what art he directs his tongue, in *articulating* sounds into voices. *Glanville.*

In the mean time they have ordered the preliminary treaty to be published, with observations on each *article*, in order to quiet the minds of his people.

Steele.

ARTICLE, in grammar, is a particule used in most languages for the declining of nouns, and denoting their several cases and genders. The

use of them chiefly arises in languages that have no different terminations to express the different circumstances of nouns. The Latins have no articles; but the Greeks, and most of the modern languages, have had recourse to them for fixing and ascertaining the vague signification of common and appellative names. Many have been the controversies among grammarians upon the use and meaning of these words. Mr. Harris, whose knowledge was derived from the Greek language and Greek grammarians, and whose principles are contradicted by the slightest acquaintance with the Teutonic and Arabic, leads us through many a maze; and we might have wandered till this moment, if Mr. Tooke, in his observations on the word *that*, in his *Epea Pteroenta*, had not pointed out to us the open and straight road upon this subject. In the English language we call the words *a* and *the* articles; the Germans have *ein* and *der*; the French *un* and *le*; the Greeks δ ; the Hebrews \aleph : but the unfortunate Latins are said to be without these joints and pegs in speech. But if one language is without them, they are, it is evident, not essential to language; and it will be found difficult to make such a definition as shall exclude a variety of words, such as *hic*, *this*, *that*, &c. from making a part of this division. In the languages above-mentioned the precise meaning of the words *the*, *der*, *le*, δ , and \aleph , cannot at first sight be ascertained. The English word *a* points obscurely to its meaning, but the German *ein* and the French *un* clear the road for investigation. They are to be found continually applied to substantives, and mean *one*. If a thing is generally reported, we say in English, 'they say,' meaning a great number say so: and so in French it is *on dit*, or *unus dicit*, 'one person says so,' meaning more than one person by an ellipsis very common in that language: in German it is *man sagt*, by man, meaning man in general. We have thus found, that in two languages one of the articles is merely a word of number. Probably it may be so in English; *a* may mean *one*, or it is an abbreviation of *any*. By trying the two senses it is evident that *any* cannot be applied in the room of *a*, but that *one* always can: and hence we might conclude that *a* and *an* are only other words for *one*, and answer to the German *ein*.

The article *the*, as it is called, may not discover itself so easily. Yet let us try the same analogy, for the etymology of it is not ascertained. The answers to *der* of the Germans, and *le* of the French: but what is *le*? the *ille* of the Latins; and hence we may reasonably presume that our word *the* is no more an article than *ille*, and in fact that it comes from some adjective of the same signification. Let us try by etymology. In German we have *der*, *die*, *das*; which was anciently *ther*, *thia* (*thio thiu*) *thaz*, and in the plural *thier* (*thier*). This looks very much like our *the*. In the Anglo-Saxon we find *sa*, *seo*, *that*: in Islandic, *sa*, *su*, *that*: in Gothic, *sa*, *so*, *thata*: in Hebrew, \aleph \aleph \aleph , \aleph \aleph \aleph : etymologists perhaps will not be displeas'd at our making the words \aleph and *the* proceed from the same original; and we shall not be afraid of exposing ourselves to the laughter of critics, if we refer the Doric $\tau\eta\upsilon\omicron\varsigma$ to the same stock. If we

are right in our conjectures, the word *the* is as much a pronoun as the *ille* of the Latins; but, if persons choose to have a distinct class of words under the name of articles, we may say that the English has two, *a* and *the*, which 'serve to define and ascertain any particular object, so as to distinguish it from the other object of the general class to which it belongs.'

Father Buffier distinguishes a third kind of articles in French, which he calls intermediate or partitive, serving to denote part of the thing expressed by the substantives they are added to; as, *des sçavants ont cru*, 'some learned men have supposed;' 'I want *de la lumiere*, 'some light.' The use and distinction of the definite and indefinite articles *le* or *la*, and *de* or *du*, make one of the greatest difficulties in the French language; as being entirely arbitrary, and only to be acquired by practice.

The most philosophical and probable account is that which has been so ably illustrated by the learned bishop Middleton; viz. that it is neither more nor less than the demonstrative or relative pronoun, for both were originally the same. The article, together with its adjunct, forms in fact a proposition, in which the participle of existence is either expressed or understood, and which involves a relation to something before said by the speaker, or which is supposed to pass in the mind of the speaker. Thus, *γέρων* signifies generally 'old man;' but *ὁ γέρων* is equivalent to *ὁ*, *γέρων ὁ*, where the pronoun *ὁ*, 'this,' implies that the old man now spoken of has been mentioned before, or that he is in some way or other known to the hearer or the speaker.

ARTICLE, ARTICULUS, in anatomy, a joint, or juncture, of two or more bones of the body.

ARTICLE, in arithmetic, sometimes signifies the number 10, or any number justly divisible into ten parts, as 20, 30, 40, &c.

ARTICLE OF FAITH is by some defined a point of Christian doctrine, which we are obliged to believe as having been revealed by God himself, and allowed and established as such by the church. The thirty-nine articles were founded, for the most part, upon a body of articles compiled and published in the reign of Edward VI. They were first passed in the convocation, and confirmed by royal authority in 1562. They were afterwards ratified anew in the year 1571, and again by Charles I. The law requires a subscription to these articles of all persons ordained to be deacons or priests, 13 El. cap. 12; of all clergymen inducted to any ecclesiastical living, by the same statute; and of licensed lecturers and curates, 13 El. cap. 12 and 13, and 11 Ch. II. cap. 4; of the heads of colleges, of chancellors, officials and commissaries, and of schoolmasters. By 1 William III. cap. 10. dissenting teachers are to subscribe to all except the thirty-fourth, thirty-fifth, and thirty-sixth, and part of the twentieth, and in the case of Anabaptists, except also part of the twenty-seventh; otherwise they are exempted from the benefits of the act of toleration. See CHURCH OF ENGLAND.

ARTICLES OF THE CLERGY, ARTICULI CLERI, are certain statutes touching persons and causes ecclesiastical, made under Edw. II. and III.

ARTICLES OF LAMBETH were nine articles on the subject of predestination, and the limitation

of saving grace, which were drawn up by archbishop Whitgift, and recommended to the attention of the students of Cambridge, in consequence of some disputes which were raised in the university at that time on the above-mentioned points. They were, however, merely declaratory of the doctrines of the church of England, and were not imposed as of public authority.

ARTICULARIS NERVUS. See ANATOMY, Index.

ARTICULATE SOUNDS are such as express the letters, syllables, or words, of an alphabet or language: such are formed by the human voice, and by some few birds, as parrots, &c.

ARTICULATED LIBEL, libellus articulatus, in law, that wherein the parts of a fact are set forth to the judge in short, distinct articles.

ARTICULATION, in anatomy. See ANATOMY, Index.

ARTICULATION, in botany, is the connexion of parts that consist of joints or knees, such as the pods of French honey-suckles, which, when ripe, divide into so many parts as there are knees or joints; also those parts of plants which swell into nodes or joints, and which usually send forth branches.

ARTICULATION, in grammar, a distinct pronunciation of words and syllables.

ARTIFICERS, among the Romans, had their peculiar temples, where they assembled and chose their own patron, or advocate, to defend their causes; they were exempted from all personal services. Taruntenus Paternus reckons thirty-two species of artificers, and Constantine thirty-five, who enjoyed this privilege. Artificers were held a degree below merchants, and argentarii or money-changers, and their employment more sordid. Some deny, that in the earliest ages of the Roman state, artificers were ranked in the number of citizens: others, who assert their citizenship, allow that they were held in contempt, as being unfit for war, and so poor that they could scarcely pay any taxes. For which reason they were not entered among the citizens in the censor's books; the design of the census being only to see what number of persons were yearly fit to bear arms, and to pay taxes towards the support of the state. In almost all ages, till the present, and under most forms of government, artificers have been too little respected. By means of the arts, the minds of men are engaged in inventions beneficial to the whole community; and thus prove the grand preservative against that barbarism and brutality, which ever attend indolence and induce stupidity. Ramazini has a treatise on the diseases of artificers.

ARTIFICIAL DAY, the time between the sun's rising and setting in any position of the hemisphere.

ARTIFICIAL LINES, on a sector or scale, are lines so contrived as to represent the logarithmick lines and tangents; which, by the help of the line of numbers, solve, with tolerable exactness, questions in trigonometry, navigation, &c. Chambers

ARTIFICIAL MUSIC, that which is according to the rules of art; or executed by instruments invented by art. It is also used, in another sense, for some artful contrivance in music; as when a piece is sung in two parts; one of which is by *B molle*, or flat and the other by *B sharp*.

ARTILLERY.

ARTILLERY. Fr. *artillerie*. Of doubtful origin.

Have I not heard great ordnance in the field?
And heav'n's artillery thunder in the skies?

Shakspeare.

I'll to the tower with all the haste I can,
To view th' artillery and ammunition. *Id.*

And Jonathan gave his artillery unto his lad, and
said unto him; Go, carry them unto the city. *1 Samuel.*

As when two black clouds
With heaven's artillery fraught, come rattling on
Over the Caspian, then stand front to front
Hov'ring a space, till winds the signal blow
To join their dark encounter in mid air.

Milton's Paradise Lost, b. ii.

Upon one wing the artillery was drawn, being six-
teen pieces; every piece having pioneers, to plain
the ways. *Hayward.*

He that views a fort to take it,
Plants his artillery against the weakest place.

Denham.

ARTILLERY, in its general sense, denotes,
1. The offensive apparatus of war, particularly
of the missile kind. Among the French the
term was anciently appropriated to archery.
In its modern signification it denotes certain fire-
arms mounted on carriages and ready for action,
with their balls, bombs, grenades, rockets, &c.
2. In a more extensive meaning, it includes the
means which facilitate their motion and trans-
port, the vehicles over which they traverse rivers,
every thing, in short, necessary to them, or that
belongs to a train of artillery. 3. In a sense
still more extensive, the word comprehends
the men and officers destined for the service
of the artillery. 4. By the term artillery is
likewise understood the science which the
officers of artillery ought to possess.

SECT. I.—OF ANCIENT MISSILES AND MILI-
TARY ENGINES.

The missiles of the ancients were of three
kinds, viz. on the principle of the cross-bow, the
sling, and the recoil of twisted ropes. The first
sent forward darts and sometimes combustible
arrows; the second was the balista kind, here-
after described; the third acted like the boy's
bone bow, which by means of a wooden lever
and a twisted string ejects a plum-stone. Dr.
Meyrick has had the good fortune to meet in an
ancient manuscript with actual delineations of
the leading kinds of these engines used in the middle
ages. The balista seems only to have been a
large beam, rather crooked, resting at about two-
thirds of its length on a forked support; if of
three legs, then called trepied. Plate, ANCIENT
ARTILLERY, fig. 1. At the long end was a great
pear-shaped bag, tied to the beam by a stout
rope. At the short end was a large box full of
stones. The long end being suddenly released,
slung upon the enemy the contents of the bag,
through being jerked up by the great weight of
the stone box. The onager, fig. 2, threw a like
bag of stones, but there was no stone-box, the
beam being impelled by its position between

twisted ropes inclined to recoil. Besides stones,
were also used balls of earth, probably baked
pelotes, corrupted into pellets and bullets. It
will be sufficient therefore to enumerate shortly
the machines, though it is to be recollected, that
ancient authors are perpetually confounding the
appellations. The arbalist is described in 1342
as a large cross-bow, furnished with a hundred
gogions, or balls, and grapple to draw it up.

The balista is said to be a Phœnician invention
for throwing huge stones, confounded sometimes
with the catapult, which threw darts, a Syrian
contrivance, conveyed to the Syracusans, whence
it was brought into Greece by Philip of Macedon.
Accounts of the construction vary, but the cross-
bow principle of action seems the most proba-
ble. The scorio is a smaller kind of catap-
ult. In the middle ages, besides the balista,
catapult, onager, and scorpion, Grose mentions
the mangona, and its diminutive mangonel,
similar to the balista. The trebuchet or trip-
getis, for throwing stones, which seems to have
been the same as the trepied, before mentioned,
though Dr. Meyrick says the term trebuchet,
appears to imply a military engine, which ejected
its ammunition from a trap-door, trebuchetto.
The petiary, matafunda, bugles or bibles, cou-
illart, and war-wolf (in one sense) also machines
for ejecting stones. The bicolle, carreaux or
quarrels, and the espringal, calculated for throw-
ing large darts, called muchetæ; and sometimes
viretons, i. e. arrows with the feathers put di-
agonally so as to occasion them to turn in the air,
but it was not limited to darts; for according to
Dr. Meyrick, v. ii. p. 53, in 1342 the gates
and towers of Norwich were furnished with
thirty espringolds for casting great stones, and
to every espringold a hundred gogions or balls
fastened up in a box, with ropes and other accou-
trements belonging to them; which illustrates
the construction before given. The robinet and
mate-griffon (i. e. destroyer of the Greeks) threw
both darts and stones.

The manu-balista, or cross-bow, supposed to
be of Sicilian and Cretan origin, was perhaps the
most important machine of this kind, and intro-
duced into Europe by the Crusades. It was
known in England, at least for use in the chase,
as early as the time of the Conquest. Its applica-
tion to warlike uses (not its introduction) by
Richard I. is well supported; it was used in
Italy in 1139. A legionary soldier appears on
an ancient seal endeavouring to bend the arcu-
balist with his foot. Five years earlier, mention
is made of turni balisterii, or the arbaleste-a-tour,
that drawn up by a turn; and in 1320, of the
balista grossa de molinellis, or one wound by a
moulinet or windlass, see fig. 6, and the balista
grossa de arganellis, i. e. one furnished with
tubes for ejecting the Greek fire. The cross-
bows used in the reign of Henry VII. were of
two kinds; the latch, with its wide and thick
bender, for quarrels, and the prodd for bullets.
The stock of the former was short and straight,

not much exceeding two feet, and the bow was bent by the windlass or moulinet.

Of the important *battering ram* Pliny and others have made Epeus the inventor, during the siege of Troy; but as it is not mentioned by Homer, nor any Greek writer, Vitruvius and Tertulian more probably assign the invention to Pephasmenon, a Tyrian, in the army of Carthage, during the siege of Cadiz. There were three kinds of rams; one suspended, fig. 5; the second running upon rollers, fig. 3; the third carried by the men who worked it, fig. 5. At Haguenau, and Morviedro, the ancient Saguntum, are the remains of two: one is topped with a strong head of iron, square and of one piece; the other consists of three pieces, has a ram's head, and is similar to one on the arch of Severus. The ram was used in the middle ages; and Sir Christopher Wren, in throwing down old walls, found no machine equal to it, particularly in disjuncting the stones. The momentum of one, twenty-eight inches diameter, 180 feet long, with a head of a ton and a half weighed 41,112 lbs. and worked by a thousand men, was about equal to a point-blank shot from a thirty-pounder.

Hardly, perhaps, to be called artillery, but materially assisting their operations were the ancient *musculus* or *testudo* a covered machine, probably the subsequent sow, a very low shed, long and very sharp roofed; used to advance to the wall, and overturn it by sap. The *pluteus*, a machine covered with osier work and hides, running upon three wheels, one in the middle, and two at the extremities. The *cat*, also a covered shed, occasionally fixed on wheels, and used for protecting soldiers employed in filling up the ditch, preparing the way for the movable tower, mining the wall, &c. Some of these cats had crenelles and chinks, from whence the archers could discharge their arrows. These were called *castellated cats*; and sometimes under cover of this machine, the besiegers worked a small kind of ram; fig. 4. Dr. Meyrick, from an ancient illumination, has engraved one of these, called the *chaschateil* or *cat castle*. It resembles in form a modern four-post bedstead upon wheels. A miner is working under it with a pick-axe. And to the same purpose the *vinca*, another shed, was applied.

The *belfragium* or *belfron*, was a tower with stories, moved up to the walls. A *cat*, made of osier twigs and leather, and covered with planks, was used to protect those who filled up the ditches preparatory to wheeling upon them the *belfries*; from this use of the *cat*, was derived the French word *eschaufaux*, an elevated floor, and subsequently the English word *scaffold*. Elsewhere Dr. Meyrick says, the *catti versatiles*, were *chats finlx* furnished with drawbridges. The chief *belfries* were called *breftachix* or *breftaches*. William de Breton says, he caused to be made double *breftaches* in seven different places. These were wooden castles, very highly fortified, surrounded with double quadrangular fosses, at a proportionate distance from each other, with drawbridges thrown across them, and he had not only these filled with armed men, but the interior surface of each foss, and

thus he surrounded the besieged by his works' Such wooden castles were also called *bastiles*. An interesting print of a movable *belfroi* is given by Grose. It consists of a ground-floor occupied by a ram, and four upper stories by archers and cross-bowmen; the highest story rose above the walls, and from that directly below, a drawbridge was let down, and rested upon the wall; see our fig. 3. Some of these towers used by the early ancients were of amazing magnitude, being with pyramids twenty, fifteen, or ten stages or floors.

The *prickly cat*, or *felis echinata*, was a beam, bristled with oaken teeth, which, being hung at an embrasure, could be let down upon an enemy. For the same purpose was used the *fituca bellica* or war-hammer, fitted with curved nails and hooks, and suspended by a chain, to draw up the enemy from below.

Missive wheels were formed of mill-stones joined by an oaken axis, and let down upon besiegers; *missive chariots* were rolled down an inclined plane, and retained by chains to discharge hot or cold stones. In the middle age the machines were commonly made upon the spot. Hogsheads full of stones were used in the reign of Edward I. as a protecting rampart to defend the workmen in sieges.

SECT. II.—OF MODERN ARTILLERY.

According to Du Cange the word *artillery* (*ars telaria*, meaning bows, arrows, and all implements of war,) first occurs in Rymer. Grose is confirmed by Dr. Meyrick in assigning the introduction of it to the fourteenth century.

Cannon called *dolia ignivoma*, or *fire-flashing vessels*, in Spain, were known in Italy as early as the year 1351, and were used by our Edward III. They were termed by the French, *gunnæ*, and appear at first to have been of two kinds—a large one for discharging stones, called a *bombard*, and a smaller sort for discharging darts or quarrels. In 1377, 1 Richard II. Thomas Norbury was directed to provide from Thomas Restwold of London, two great and two less engines, called *cannons*, 600 stone shot for the same, and salt-petre, charcoal, and other ammunition, for stores, to be sent to the castle of Bristol. At the first invention of cannon, darts and bolts were shot from them; but, before these, stones were used instead, for, in 1388, a stone bullet, which weighed 195 lbs., was discharged from a *bombard* called the *trevisan*.

The *bombard* was so called from the Greek *βομβος*, which expressed the noise it made in the firing. It was a Greek invention, and there is some reason to conceive that gunpowder owed its origin to the same people. At first used only in fire-works amusingly, its discovery is involved in obscurity. From a tract on Pyrotechny by Marcus Græcus, Friar Bacon, in 1270, learned that its composition was two pounds of charcoal, one of sulphur, and six of salt-petre, well pulverised and mixed. It was first made in England in the time of Elizabeth. At first it was not corned, but remained in its mealed state. It was then called *serpentine powder*, Meyrick, v. iii. p. 71. The first *bombards* were made of bars of iron, strengthened with welded hoops of the

same metal. They were short with large bores, and were made with chambers, in imitation of the tubes which ejected the Greek fire. These chambers consisted of the lower half of the cylinder, the upper being open for the admission of the can, or canister, which held the charge, from whence probably arose the term cannon. One of these may be seen in the tower of London, and there is another at Rhodes of the sixteenth century, on its original carriage, and a stone ball to fire from it. It is nineteen feet in length, two feet eight inches in diameter, its calibre two feet, and its thickness four inches. About half the length is of a less diameter, and in this, as in a chamber, was placed the powder, while the ball was in the larger part. The carriage was made of timber, placed lengthways, and cramped together. These bombardiers were the only kind of cannon employed in the fourteenth century, and were of the howitzer kind, in use before mortars. After this invention of bombs, that of carcasses of different kinds soon followed. The former, according to Strada, took place in 1588. Grenades are said to have been first used in 1594 in which year the howitzer was invented by the Germans. The bomb being intended to beat down buildings in its fall, or to break and destroy every thing around it, by the pieces of broken iron scattered in all directions by its explosions, the end proposed by the carcass and grenade was to burn the town by means of fire-balls. The petard for forcing gates was invented in France, a short time before the year 1579, and soon after introduced into England.

The term bombard generally designates battering guns and mortars; but the word is also applied to lighter cannon. Accordingly Dr. Meyrick calls a cannon engraved by Strutt, a bombard on a carriage, light in proportion to the bulk of the piece. Its trail consists of a prolongation of the cascabele, which rests on the ground, a block of wood serving as a quoin for the purpose of depression. Admitting that cannon were not used in the field till the fifteenth century, this gun, for it is very small, is the kind to which Froissart alludes, when he mentions two hundred carts loaded with cannon and artillery; cannonades with bars of iron and quarrels headed with brass, and cannon mounted on walls and battlements. The balls were of stone adapted to the calibre. In 1434 it is said that the English had many kinds of projectiles, 'cannons, culverines, and other vulgaires,' more properly vulgaires, the ordinary kind. The scorpion was another sort. In an illuminated copy of the Roman de la Rose, done at the commencement of the reign of Edward IV. 1461, is the delineation of an iron cannon. The piece is placed in a kind of trough, or bed of wood, which is continued to the earth, not unlike a modern horse-artillery trail. Grose very properly says, that most of the earliest cannons were mere cylinders, fixed on sledges and being often composed of iron bars, iron plates rolled, or even jacked leather hooped, could be fired, because they were loaded by chambers fixed in at the breech. At this time they were generally purchased from abroad; and though Henry VII. and VIII. had Flemish gunners to teach the art, yet they did not

understand it upon mathematical principles; and in the sixteenth century the ordnance rarely made more than one discharge, the cavalry being able to charge them before they could load again. Aliens were employed in 1543 in casting great brass ordnance, though one John Owen was said to have so done in 1521. In 1626, 2 Charles I. one Arnold Rotespen had a patent for making guns in a manner before unknown in this kingdom.

Culverines were an early denomination of a species of large cannon; and when the distinction between battering-pieces (all above twelve pounders) and field-pieces commenced, according to Dr. Meyrick, temp. Henry VIII. the appellations were numerous. These names were derived from the tubes which had been used to eject the Greek fire, being fashioned so as to represent the mouths of monsters. The basilisk, the largest, shot stones of 200 pounds weight. It was so denominated from a basilisk sculptured upon it. The shot in this reign consisted of iron, lead, and stone balls; and ladles and sponges were used. Different proportions were given by various nations to pieces of the same denomination; but the following table of Ordnance in the reign of Elizabeth, applies in the main to the times immediately preceding:

Denomination.	Pounders.	In. Bore.
Cannon Royal	66	8½
Cannon	60	8
Cannon Serpentine	53½	7
Bastard Cannon	41	7
Demi-cannon	33	6½
Cannon Petro'	24	6
Culverin	17½	5½
Basilisk	15	5
Demi-culverin	9½	4
Bastard Culverin	5	4
Sacar	5½	3½
Minion	4	3½
Faulcon	2	2½
Falconet	1½	2
Serpentine	½	1½
Rabinet	½	½

The change introduced in the military art by the modern artillery, Dr. Smith observes, has enhanced greatly both the expense of exercising and disciplining any particular number of soldiers in time of peace, and that of employing them in time of war. Both their arms and ammunition are become more expensive. A musket is a more expensive machine than a javelin or a bow and arrows; a cannon or a mortar than a balista or a catapulta. The powder which is spent in a modern review, is lost irrecoverably, and occasions a very considerable expense. The javelins and arrows which were thrown or shot in an ancient one, could easily be picked up again, and were besides of very little value. The can-

non and the mortar are not only much dearer, but much heavier machines than the balista or catapult, and require a greater expense not only to prepare them for the field but to carry them to it. As the superiority of the modern artillery too over that of the ancients is very great, it has become much more difficult, and consequently much more expensive, to fortify a town so as to resist, even for a few weeks, the attack of that superior artillery. In modern war, the great expense of fire-arms gives an evident advantage to the nation which can best afford that expense; and consequently to an opulent and civilised, over a poor and barbarous nation. In ancient times, the opulent and civilised found it difficult to defend themselves against the poor and barbarous nations. In modern times, the poor and barbarous find it difficult to defend themselves against the opulent and civilised. The invention of fire-arms, therefore, an invention, which at first sight appears to be so pernicious, is certainly favorable, both to the permanency and to the extension of civilisation. And, on the whole, the invention of gun-powder and modern artillery may be said to have saved the effusion of human blood. Equestrian engagements (the principles on which cavalry act being nearly the same in every age,) are still similar in circumstances to those which appear so extraordinary in the battles of antiquity.

The present artillery of Great Britain is admitted to be the most perfect force of that description in Europe. It was until recently divided into the artillery of the park, the horse artillery, and the battalion guns, viz. all the light pieces of ordnance attached to regiments of the line. This latter description, however, has been discontinued of late, and brigades of foot and horse now comprehend the whole of our regular artillery.

A brigade of foot artillery has either five medium 12-pounders and a heavy 5½-inch howitzer; five 9-pounders and ditto; five long 6-pounders and ditto; five light 6-pounders and a light 5½-inch howitzer; or six 3-pounders when acting in a mountainous district. In the late war the 9-pounders were more generally used, as best opposed to the 8-pounders of the French army. The guns and howitzers are accompanied by ammunition cars, upon a new principle. To every brigade is a large cart, a camp equipage wagon, and spare-gun carriage, with spare wheels, and tools for a wheeler, collar-maker, and carriage-smith. The proportioning of field and battering ordnance, for foreign service, is a business of great importance, from the knowledge which is requisite to fix upon all the numerous articles to accompany the service, and the method to be pursued in equalising, arranging, and disposing of the guns, ammunition, and stores. No certain criterion can ever be established as to the proportion of artillery to be sent upon any expedition, as it must depend entirely upon the nature of the service; and great changes are generally made to suit the ideas of the officer who is to command the army, and also those of the officer of artillery, who may be selected to accompany it. But two brigades of field artillery to a division of an army consisting of 6000 men, may be considered a good proportion, independent of the reserve park.

A troop of British horse artillery has generally five 6-pounders and one light 5½-inch howitzer. The French have generally 8-pounders and a 6-inch howitzer. Each troop consisting of one captain, one second captain, three subalterns, two staff serjeants, twelve non-commissioned officers, seventy-five gunners, forty-six drivers, six artificers, and one trumpeter, with eighty-six draught horses, and fifty-six riding horses, and six pieces of ordnance, with carriages for the conveyance of ammunition, camp equipage, and stores. Horse artillery was brought into the service of this country by the duke of Richmond in the year 1792. There is a colonel-commandant, two colonels en second, four lieutenant-colonels, and one major, attached to it. The movements of horse artillery are made with great celerity, and it has been found, that they are perfectly adapted to act with cavalry in the field, in their most rapid movements, and are considered as forming an essential addition to the artillery service.

The royal artillery drivers are a corps first formed about twelve years ago, by the duke of Richmond. Previous to the corps being established, the horses and drivers were provided by contract; but, as no reliance could be placed on the service of either men or horses so procured, it was found absolutely necessary to abolish so unilitary and destructive a plan; and to employ able men well trained to the service. The artillery horses are now kept in the highest condition, the drivers being thoroughly drilled to the manœuvres of artillery, and capable of securing, by rapid movements, advantageous positions in the field. This change arises from the high state of excellence in which the brigades are equipped, and from the artillery men being, in particular cases, mounted upon the cars attending the brigades.

A park of artillery is a sort of movable supernumerary detachment, containing not only light guns, to replace such as may be lost or taken, but 12-pounders, or 18-pounders, with 8 inch howitzers, for the purpose of defending important positions, entrenched posts, &c. breaking down bridges, and conducting sieges. Attached to it also are the reserve officers and men of this service. In expedition service, where disembarkations of artillery take place, the dépôt of reserve carriages, ammunition and stores, is usually formed near to the spot where the articles are landed from the ships, and a communication is kept up between the advanced park and the dépôt, from whence the articles are forwarded as demanded for the immediate exigencies of the park. See CANNON AND FORTIFICATION.

Regiments of artillery are always encamped, half on the right and half on the left of the park. The company of bombardiers (when they are formed into companies, which is the case in almost every nation except England) always takes the right of the whole, and the lieutenant colonel's company the left; next to the bombardiers, the colonels, the majors, &c. so that the two youngest are next but one to the centre or park; the two companies next to the park are the miners on the right, and the artificers on the left. In the rear of, and thirty-six feet from, the park, are encamped the civil list, all in one line.

The following Tables exhibit the latest official regulations for the proportion and disposition of the ammunition attached to the field-pieces of our army.

TABLE I.
HEAVY 5½ INCH HOWITZER.

Description of carriage.	Where carried.	Round Shot.	Case Shot.			Total Shot.	Cartridges.			
			Heavy.	Light.	Spherical.		2-lb.	10 ozs.	6 ozs.

ARTIMOMANTICO, a metallic compound invented by a gentleman at Leghorn. It is of the same weight as gold of eighteen carats, and can be made like that of twenty-four. Buttons are manufactured from it at Bologna, and sold for 50 cents the dozen. Artimomantico is soft and bends, and derives its superiority over other gold-coloured metals, from its not tarnishing.

ARTISCUS; from *aproc*, bread; in medicine, denotes a troche, more particularly that prepared with vipers' flesh mixed up with bread, to be used in the composition of Venice treacle.

ARTIST. See **ART**.

An **ARTIST** has more correctly been defined one who practises any of the liberal arts as a profession, in distinction from the artisan who mixes them with trade and commerce. The builder, it is said, should not be called an architect, nor should the sign-painter, the figure-caster, or plasterer, the chair-sculptor, commonly called cabinet-maker, the paper-hanger, or wall-decorator, be called artists, because their employments do not consist in the exercise of the higher faculties of the mind, but in practising lower departments of art, or in executing the thoughts and designs of others.

ARTIZOOS; from *arti* short, and *ζωη*, life; is used by some ancient physicians for an infant short-lived by reason of a difficult birth.

ARTOBRIGA, an ancient town of Vindelicia, now called Altbürg, in Bavaria, on the Danube, below Ingolstadt, according to Aventinus; but Cluverius supposes it to be Labenau on the Saltzbach, below Lauffen, in the archbishopric of Saltsburg.

ARTOCARPUS; from *aproc*, bread, and *καρπος*, fruit; the bread-fruit tree; a genus of the monandria order and monœcia class; natural order, urticæ. It has a cylindrical amentum, thickens gradually, and is covered with flowers: the male and female in a different amentum. In the male, *cal.* none; *cor.* bivalved. In the female no calyx nor corolla; stylus, one, and the drupa is many celled. The species are, *artocarpus incisa*, *sitodium incisum*, *radermachia incisa*, *soccus lanosus*, *seu granosus*, in French *le rima*, *ou fruit à pain*, bread-fruit tree, native of the Molucca Islands. *Artocarpus integrifolia*, *sitodium macrocarpon*, *seu cauliflorum*, *radermachia integra*, *soccus arboreus*, *seu tojacca-marum Indica*, Indian jaca tree, a shrub, native of the East Indies. *Artocarpus Philippensis*, a shrub, native of the Philippine Islands. *Artocarpus pubescens*, *ansjeli*, *seu castania malabarica*, a shrub, native of Malabar. Though this tree has been mentioned by many voyagers, particularly by Dampier, Rumphius, and Lord Anson, yet very little notice seems to have been taken of it till the return of Captain Wallis from the South Seas. Dampier states that in Guam, one of the Ladrone islands, 'there is a certain fruit called the bread-fruit, growing on a tree as big as our large apple-trees, with dark leaves. It is round, and grows on the boughs like apples, of the bigness of a good penny loaf: when ripe it turns yellow, soft, and sweet, but the natives take it green, and bake it in an oven till the rind is black; this they scrape off and eat the inside,

which is soft and white, like the inside of new-baked bread, having neither seed nor stone; but if kept above twenty-four hours it is harsh. As this fruit is in season eight months in the year, the natives feed upon no other sort of bread during that time.' Rumphius says, 'the fruit is shaped like a heart, and increases to the size of a child's head. Its surface or rind is thick, green, and covered everywhere with warts of a quadrangular or hexagonal figure, like cut diamonds, but without points. The more flat and smooth these warts are the fewer seeds are contained in the fruit, and the greater is the quantity of pith, and that of a more glutinous nature. The internal part of the rind, or peel, consists of a fleshy substance, full of twisted fibres, which have the appearance of fine wool; these adhere to and in some measure form it. The fleshy part becomes softer towards the middle, where there is a small cavity formed without any nuts or seeds, except in one species which has but a small number, and this sort is not good unless it is baked or prepared some other way; but if the outward rind be taken off, and the fibrous flesh dried and afterwards boiled with meat as we do cabbage, it has then the taste of artichoke bottoms. The inhabitants of Amboyna dress it in the liquor of cocoa-nuts, but they prefer it roasted on coals till the outward part or peel is burnt. They afterwards cut it into pieces and eat it with the milk of the cocoa-nut. Some people make fritters of it, or fry it in oil; and others, as the Sumatrans, dry the internal soft part, and keep it to use, instead of bread, with other food. It affords a great deal of nourishment, and is very satisfying, therefore proper for hard-working people; and being of a gentle astringent quality is good for persons of a laxative habit of body. It is more nourishing boiled in our manner with fat meat, than roasted on coals. The milky juice which distils from the trunk, boiled with the cocoa-nut oil, makes a very strong bird-lime. This tree is to be found on the eastern parts of Sumatra, and in the Malay language is called *soccus* and *socum capas*. It grows likewise about the town of Bantam in Java, and in Balega and Madura.'

In 1791 a vessel was fitted out for the purpose of conveying a quantity of these inestimable trees to various parts of his majesty's colonies, under the command of Captain Bligh, who set sail on the 2d of August, and arrived at Otaheite April 8, 1792. The number of plants taken on board at Otaheite was 2634, in 1281 pots, tubs, and cases; and of these 1151 were bread-fruit trees. When they arrived at Coupang 200 plants were dead; but the rest were in good order. They arrived at St. Helena with 830 fine bread-fruit trees, besides other plants. Here they left some of them, and from hence the East Indies may be supplied with them. On their arrival at St. Vincent's they had 678 bread-fruit trees. Nearly half this cargo was deposited here for the use of the Windward Islands; and the remainder, intended for the Leeward Islands, was conveyed to Jamaica, and distributed as the governor and council of Jamaica pleased to direct. The exact number of bread-fruit trees brought to Jamaica was 352, out of which five only were

reserved for the botanic garden at Kew. There is a distinction between that which bears fruit with stones or seeds, and that in which the fruit has none. The parts of fructification of that tree which bears the fruit without stones are defective. The amentum, or catkin, which contains the male parts, never expands. The styli, or female parts of the fruit, are likewise deficient: from which it follows that there can be no stones or seeds, and therefore this tree can only be propagated by suckers or layers; although it is abundantly evident that it must originally have proceeded from the seed-bearing bread-fruit tree. Instances of this kind we sometimes find in European fruit, such as the barberry and the Corinthian grape from Zant, commonly called currants, which can therefore be increased only by layers and cuttings. Dr. Solander was assured by the oldest inhabitants of Otaheite, and the adjoining islands, that they well remembered there was formerly plenty of the seed-bearing bread-fruit; but they had been neglected on account of the preference given to the bread-fruit without seed, which they propagate by suckers.

ARTOIS, a ci-devant province of France, extremely fertile, and formerly one of the seven-teen provinces of the Netherlands. The name was derived from the Atrebatæ, the ancient inhabitants. Its greatest length from north to south was about twenty-four leagues, and its breadth about twelve, being bounded on the south and west by Picardy; on the east by Hainault; and on the north by Flanders. It is now included in the department of the Straits of Calais. Artois was always accounted a very productive province. It is rich in corn and hops, but is deficient in wood, and yields little wine or fruit. The chief articles of export are grain, flax, hops, wool, oil, cabbage, and rape-seed.

ARTOMELI; from *αρτος*, bread, and *μελι*, honey; in ancient pharmacy, a kind of cataplasma, prepared of bread and honey.

ARTOTYRITES; from *αρτος* and *τυρος*, cheese; a branch of the ancient Montanists, who first appeared in the second century in Galatia. They used bread and cheese in the Eucharist, or perhaps bread baked with cheese. Their reason was, that the first men offered to God not only the fruits of the earth, but of their flocks too. The artotyrites admitted women to the priesthood, and even to be bishops; and Epiphanius informs us, that it was a common thing to see seven girls at once enter into their church robed in white, and holding torches in their hands; where they wept and bewailed the wretchedness of human nature, and the miseries of this life.

ARTZEN, a market-town and bailiwick of Calenberg, in the principality of Hanover, between the Hemme and Weser. To the bailiwick belong twenty-two villages and the castle of Furstenberg, formerly the property of the count of Osterheim. This town is the seat of an ecclesiastical superintendent.

ARVAD, or ARADUS, an ancient city of Phœnicia, built on a small island, south of Tyre, about three miles from the continent. It was formerly famous for commerce and riches, and shared the fate of Tyre. It is now called Ruwaddé, and belongs to the Turks. It is quite ruinous, having only an old fort and a few can-

non to defend it; but the height of the island gives it a fine appearance from a distance.

ARVAL, a town of Hindostan, in the district and province of Bahar, forty miles south-west of Patna.

ARVALES FRATRES, in Roman antiquity, a college of twelve priests, instituted by Romulus, and chosen out of the most noble families, himself being one of the body: they assisted in the sacrifices of the ambervalia, annually offered to Ceres and Bacchus for the prosperity of the fruits of the earth, when they wore on their heads crowns made of ears of corn. The origin of this institution was as follows: Acca Laurentia, Romulus' nurse, was accustomed once a year to make a solemn sacrifice for a blessing on the fields, her twelve sons always assisting her in the solemnity; but at last losing one of them, Romulus offered himself to supply his place, and gave this small society the name of Arvales fratres. This order was in great repute at Rome; they held the dignity for life, and never lost it on account of imprisonment or banishment.

ARUANUS, in conchology, a species of murex, found on the coast of New Guinea. The tail is patulous; the spire crowned with spines. This is the buccinum aruanum of Rumphius.

ARVENSIS, in entomology, a species of curculio; gray, with three lines on the thorax; the wing-cases rufous, and tessalated. Also a species of cicada, a native of Denmark; yellow; abdomen and sides black. A species of phalæna; the phalæna noctua of Linnæus. The wings are brown, with a transverse yellow spot in the middle; margin brown. This is the noctua brunnea of Schmetterl. Also a species of Vespa, found in Europe, with four yellow bands on the abdomen.

ARVERNI, a brave and ancient people; one of the most powerful nations of Gaul. They claimed affinity with the Romans, as descendants from Antenor; and after their subjugation by the latter, their ancient liberty was preserved to them on account of their bravery.

ARVICOLA, in entomology, a species of scarabæus, found in Russia; the shield of the head reflected; the body black.

ARVIRAGUS, the son of Cunobelin, a British king, in the time of Claudius and Domitian.

ARUM, or WAKE-ROBIN, in botany, a genus of plants of the class monœcia; order, polyandria. There are several species, of which the following are the most remarkable. The generic characters are CAL. spathe, one-leaved: COR. none: STAM. filaments, none; anthers, sessile: PIST. germ, obovate; style, none; stigma, bearded: PER. berry, globular; seeds, several. A. arborescens, or dumb cane, is a native of the sugar islands and warm parts of America, where it grows chiefly on low grounds. A. arisarium as well as the A. proboscidium and A. tenuifolium have usually been separated from this genus, and distinguished by the general name of arilarum, or friar's cowl: the flower bears in April. A. colocasia, as well as the A. divaricatum, esculentum, peregrinum, and sagittifolium, have all mild roots, which are eaten by the inhabitants of hot countries, where they grow naturally. A. dracunculoides, or the common dragon's cane, grows naturally in most of the southern parts of Europe. A. italicum, a native of Italv. Spain,

and Portugal: they appear in the end of April or beginning of May. *A. maculatum*, or common wake-robin, grows naturally in woods and on shady banks in most parts of Britain: the flowers appear in April, and their structure has given rise to many disputes among the botanists. The receptacle is long, in the shape of a club, with the seed-buds surrounding its base. The chives are fixed to the receptacle amongst the seed-buds fixed to the fruit-stalk, and placed between two rows of tendrils, the use of which is not known. *A. trilobatum*, or arum of Ceylon, is a native of that island and some other parts of India. All the species of this plant are hardy, except the *trilobatum* and the *arborescens*. The former must be kept constantly in a stove, and the latter in a moderate hot-bed. The *arborescens* is propagated by cutting off the stalks into lengths of three or four joints, which must be left to dry six weeks or two months; for if the wounded part is not perfectly healed over before the cuttings are planted, they will rot and decay. They are then to be planted in small pots filled with light sandy earth, and plunged in a moderate hot-bed of tan, observing to let them have little water till they have taken good root. The roots of the *maculatum* and *dracunculus* are used in medicine, and differ in nothing but that the latter is somewhat stronger than the former. All the parts of the arum, particularly the root, have an extremely pungent acrimonious taste; but if dried and kept some time, it loses much of its acrimony, and becomes at length an almost insipid, farinaceous substance. This root is a powerful stimulant and attenuant. It is reckoned a medicine of great efficacy in some cachectic and chlorotic cases, in weakness of the stomach occasioned by a load of viscid phlegm. Great benefit has been obtained from it in rheumatic pains, in which it may be given from ten grains to a scruple of the fresh root twice or thrice a-day, made into a bolus or emulsion with unctuous and mucilaginous substances, which cover its pungency, and prevent its making any painful impression on the tongue. It generally excites a slight tingling sensation through the whole habit, and when the patient is kept warm in bed, produces a copious sweat. The arum was formerly an ingredient in an official preparation, the compound powder; but in that form its virtues are very precarious. Some recommend a tincture of it drawn with wine; but neither wine, water nor spirits, extract its virtues.

ARUNCI, in entomology, a species of Cicada of a ferruginous color and brown eyes.

ARUNCO, in zoology, a species of rana, or toad, larger than the common frog, but of the same color. It is found in Chili. All the feet are palmated.

ARUNCUS, GREATER MEADOW-SWEET, in botany, a genus of plants, called by Tournefort and others *barra capræ*, and by Linnæus *spiræa*. This plant has been supposed to be of the same genus with the *filipendula*, but, by the examination of the flowers, they appear to be extremely different.

ARUNDA, a town of Hispania Bætica, on the Annas, or Guadiana, now said to be Ronda in Granada, on the confines of Andalusia. Long. 5° 40' W., lat. 36° 26' N.

ARUNDEL, an ancient borough and market town of Sussex, seated on the north-west side of the Arun, over which there is a bridge. It had a harbour in which a ship of 100 tons burden might ride; but the sea had ruined it so far, that in 1733 an act passed for repairing it, and for erecting new piers, locks, &c. The river is now navigable for vessels of 200 tons and upwards, and the navigation is carried on to the Thames by means of a canal. It abounds in mullet of a very fine quality. A considerable trade in bark is carried on here. Arundel sent two members to parliament from the reign of Edward I., since the passing of the reform bill it sends one. It is mentioned in the will of Alfred, who left the castle to his brother's son. It was formerly a place of great strength, and was besieged by Henry I., by whom it was taken after a gallant resistance from Bellesone de Montgomery earl of Arundel. The castle, which belonged to the family of Howard, was until lately in a mouldering condition; but completely repaired by the late Duke of Norfolk, at a great expense. A weekly market is held here on Thursday. Population 2700. Arundel is the premier earldom in England, belonging to the illustrious family of Norfolk; and is the only title in England that goes along with the lands. It is fifty-seven miles south-west by south of London, and ten east of Chichester.

ARUNDEL OIL, in the materia medica. At Bombay, Gambroon, and Surat in the East Indies, there grows a tree which bears a nut enclosed in a rough husk, resembling the horse chestnut; and the kernel of the nut yields an oil by expression, which is of a purgative nature. A tea-spoonful of it is reckoned a dose. The tree is called, the Arundel tree at Bombay and its oil the Arundel oil. Dr. Monro thinks it probable that this is the oil of the purging nuts mentioned in Dale's pharmacologia, and the *palma Christi Indica* of Tournefort.

ARUNDEL (Thomas), archbishop of Canterbury in the reigns of Richard II. Henry IV. and Henry V., the second son of Robert, and brother of Richard earl of Arundel, who was beheaded. In 1375, at twenty-two years of age, from being archdeacon of Taunton he was raised to the bishopric of Ely. He was a great benefactor to the church and palace of this see. In 1386 he was appointed lord chancellor of England, and in 1388 translated to the archiepiscopal see of York; and in 1396 to that of Canterbury, when he resigned the chancellorship. This was the first instance of the translation of an archbishop of York to the see of Canterbury. Scarcely was he fixed in this see, when he had a contest with the university of Oxford about the right of visitation. The affair was referred to king Richard, who determined it in favor of the archbishop. At his visitation in London he revived an old constitution, by which the inhabitants of the respective parishes were obliged to pay to their rector one half-penny in the pound out of the rent of their houses. In 1398 the house of commons impeached him, together with his brother the Earl of Arundel, and the Duke of Gloucester, of high treason. The archbishop was sentenced to be banished, and within forty days to depart the kingdom on pain of death. He

retired first to France; and then to the court of Rome, where Pope Boniface IX. gave him a kind reception. About this time the duke of Lancaster, afterwards Henry IV. was in France, having also been banished by king Richard. The nobility and others, tired with the oppressions of Richard, solicited the duke to take the crown; sending over their request in a letter to archbishop Arundel, desiring him to be their advocate on this occasion with the duke. The archbishop accordingly accompanied the messengers to the duke at Paris, and of course the inviting offer, after some objections easily obviated, the duke accepted. Arundel returned with him to England, and was restored to his see. In the first year of this prince's reign, the archbishop summoned a synod which sat at St. Paul's. The next year we find him again in dispute with the commons, who moved that the revenues of the church might be applied to the service of the public: but Arundel opposed the motion with such vigor that it was negated. In 1408 Arundel began to exert himself against the Lollards, or Wicliffites, particularly against the celebrated Sir John Oldcastle, Lord Cobham. He also procured a synodical constitution, which forbade the translation of the Scriptures into the vulgar tongue. He died at Canterbury in 1413, of an inflammation in his throat, with which he was first seized, it is said, whilst pronouncing sentence upon Lord Cobham. The Lollards asserted this to be a judgment from God; and Bishop Goodwin speaks in the same manner. 'He who had withheld,' says he, 'from the people the word of God, the food of the soul, by the just judgment of God had his throat so closed, that he could not speak a single word, nor swallow meat or drink, and was so starved to death.' He was buried in the cathedral church of Canterbury, under a monument erected by himself. To this church he was a considerable benefactor: he built the lantern, tower, and a great part of the nave; gave a ring of five bells, called from him Arundel's ring, several rich vestments, a mitre encased with jewels, a silver gilt crozier, and two gold chalices.

ARUNDEL (Lady Blanch), daughter of the earl of Worcester, and wife of Lord Arundel, celebrated for her brave defence of Wardour castle against the parliamentary army, which consisted of 1300 men; and although the little garrison mustered only forty-five, yet she maintained the place for six days, and then capitulated. She died in 1649, aged sixty-six.

The ARUNDELIAN MARBLES, are ancient stones or marbles, first named after Thomas earl of Arundel, who procured them from the east, or from Henry his grandson, who presented them to the university of Oxford. They arrived in England in 1627, and then consisted of thirty-seven statues, 128 busts, and 250 inscriptions, together with a large number of altars, sarcophagi, fragments of sculpture, and an invaluable assemblage of gems; the inscriptions being principally sepulchral, and of a private nature. But one, called the Parian chronicle, from its being written at Paros, is said to have contained a chronological detail of the principal events of Greece, during a period of 1318 years, beginning with

Cecrops, before Christ 1582 years, and ending with the archonship of Diognetus, before Christ 264. It is this portion of these marbles which more particularly attracted the attention of the learned. The chronicle of the last ninety years is lost; so that the part now remaining ends at the archonship of Diotimus, 354 years before the birth of Christ; and in this fragment the inscription is at present much corroded and effaced.

The whole of these relics of antiquity, real or pretended, were purchased in Asia Minor, or in the islands of the Archipelago, by Mr. William Petty, who in the year 1624 was sent by the earl of Arundel for the purpose of making such collections for him in the east; and when brought to England were placed in gardens belonging to Arundel house. Soon after their arrival they excited general curiosity, and were inspected by Sir Robert Cotton, and other eminent men, who prevailed upon the learned Selden to employ himself in explaining the inscriptions. The following year Selden accordingly published a small volume in quarto, including about thirty-nine of them. But in the turbulent reign of Charles I. and the subsequent usurpation, Arundel-house was often deserted by the illustrious owners; and in their absence, many of these marbles were defaced and mutilated, and others either stolen or used for the ordinary purposes of architecture. The Parian chronicle in particular, was unfortunately broken. The upper part containing thirty-one epochas, is said to have been worked up in repairing a chimney in Arundel-house. Selden's work becoming very scarce, bishop Fell engaged Mr. Prideaux to publish a new edition of the inscriptions, which was printed at Oxford in 1676. In 1732, Mr. Maittaire obliged the public with a more comprehensive view of the marbles than either of his predecessors. Lastly, Dr. Chandler published a new and splendid description of them in 1763, in which he corrected many mistakes of the former editors; and in some of the inscriptions, particularly that of the Parian chronicle, supplied the lucunæ by many ingenious conjectures. We cannot here enter into the dispute respecting the authenticity of these curious stones. Sir Isaac Newton and other able chronologists and historians have paid little regard to their claims; and in 1788, a Mr. Robertson, in an essay, entitled the Parian Chronicle, boldly, and with much plausibility, asserts them to be a fabrication of comparatively modern date. This treatise was reviewed by the late professor Porson, in the Monthly Review, June 1789; that distinguished Greek scholar fully and very ably vindicating the authenticity of the Parian marbles. See also his Tracts, edited by Mr. Kidd. p. 57. The reader will thus be sufficiently acquainted with both sides of this subject.

ARUNDINACEA, in conchology, a species of sabella found in some rivers of Europe. It is subconic, and composed of fragments of the bark of reeds placed on each other.

ARUNDINACEUS, in ornithology, a species of turdus or thrush, that inhabits the reedy marshes of Europe, and is the *la rousserolle* of Buffon and Brisson; the *junco* of Ray and Willoughby; and the reed thrush of Dr. Latham. It

is rather larger than the common lark; of a ferruginous brown color; quill-feathers brown, reddish at the end. It is found in Russia and Poland.

ARUNDINETI, in entomology, a species of tipula; color whitish, with villose antennæ, and black eyes. It is found in Europe, in reedy marshes.

ARUNDINIS, a species of phalæna, living on reeds; wings cinereous with black dots, marked beneath with a central brown spot. Also a species of aphid that lives on the leaves of the wood-reed. The body is green; thorax and head brown.

ARUNDO, in botany, the reed: a genus of the digynia order, triandria class of plants; ranking in the natural method under the fourth order, gramina. The calyx consists of two valves, and the floscules are thick and downy. The following are the principal species, viz. 1. *A. arborea*, has a tree-like stalk, with narrow leaves, and in all other respects resembles the bambos. 2. *A. bambos*, or the bamboo, is a native of the East Indies and some parts of America; where it frequently attains the height of sixty feet. See *Вамбоо*. 3. *A. debax*, or manured reed, a native of warm countries, but will bear the cold of our moderate winters in the open air. It dies to the surface in autumn, but appears again in the spring ten or twelve feet high in one summer. The stalks of this species are brought from Spain and Portugal; and used by weavers, as also for making fishing-rods. 4. *A. orientalis* is what the Turks use for writing pens: it grows in a valley near mount Athos, as also on the banks of the river Jordan. None of these plants are found in Britain. 5. *A. phragmitis*, or the common marsh-reed, grows by the sides of our rivers, and in standing waters. 6. *A. versicolor*, the Indian variegated reed, supposed to be a variety of the *debax*, differing from it only in having variegated leaves.

ARUNS TARQUINIUS, the son of Tarquin II. the last king of Rome, who meeting Brutus in the first battle, after the banishment of the royal family, they mutually killed each other.

ARURA, in the middle-age writers, a field ploughed and sowed. Some writers also use the word to signify the work of a day at plough.

ARUSINI CAMPI, or **ARUSIAN FIELDS**, plains in Lucania, famous for the last battle between the Romans and Pyrrhus. That prince being at Tarentum, and hearing that the two new consuls Curius Dentatus and Cornelius Lentulus had divided their forces, the one including Lucania and the other Samnium; he divided a chosen detachment of his army into two bodies, marching with his Epirots against Dentatus, in hopes of surprising him in his camp near Beneventum. But the consul having notice of his approach, marched out of his entrenchments with a strong detachment of legionaries to meet him, repulsed his van guard, put many of the Epirots to the sword, and took some of their elephants. Curius, encouraged by this success, marched into the Arusian fields, and drew up his army in a plain, which was wide enough for his troops, but too narrow for the Epirot phalanx to act. But the king's eagerness to try his strength and skill with

so renowned a commander, stimulated him to engage at that great disadvantage. Upon the first signal the action began; and one of the king's wings giving way, victory seemed inclined to the Romans. But that wing where the king fought in person repulsed the enemy, and drove them to their entrenchments. This advantage was in great part owing to the elephants; a circumstance which Curius perceiving, commanded a body of reserve, which he had posted near the camp, to advance and attack those animals with burning torches; which frightened and annoyed them to such a degree, that they wheeled about, broke into the phalanx, and put that body into the utmost disorder. The Romans taking advantage of this confusion, charged with such fury that the enemy were entirely broken and defeated. Pyrrhus retired to Tarentum, attended only by a small body of horse, leaving the Romans in full possession of his camp; which they so much admired, that they ever after imitated it as a model.

ARUS'PEX, } Lat. *aruspex*, or *haruspex*,
ARUS'PICE, } from *ara*, an altar, and *spicere*,
ARUS'PICV. } to see, to regard.

Adorn'd with bridal pomp, she sits in state;
 The public notaries and *aruspex* wait.

Dryden's Juvenal's Satires, 10.

They [the Romans] had colleges for augurs and *aruspices*, who used to make their predictions, sometimes by fire, sometimes by flying of fowls, &c.

Howell's Letters, iii. p. 23.

A flam more senseless than the roguery
 Of old *aruspicy* and augury.

Butler's Hudibras, ii. 3.

ARUSPICES, or **HARUSPICES**, in Roman antiquity, an order of priests who pretended to foretel future events by inspecting the entrails of victims killed in sacrifice; they were also consulted on occasion of portents and prodigies. The *aruspices* were always chosen from the best families; and as their employment was of the same nature as that of the augurs, they were as much honored. Their college, as well as those of the other religious orders, had its particular registers and records. Cato, who was an augur, used to say, he wondered how one *aruspex* could look at another without laughing in his face. The *aruspici libri*, were a kind of sacred writings wherein the laws and discipline of the *aruspices* were described.

ARVUM, in ancient agriculture, properly denoted ground ploughed but not sowed. The word is sometimes extended to all arable, or corn land, in contradistinction from pasture.

ARX, in the ancient military art, a town, fort, or castle, for defence of a place. The *arx*, in ancient Rome, was a distinct edifice from the capitol, though some have confounded the two. The *arx*, properly speaking, being a place on the highest part of the Capitoline Mount, fortified with towers and pinnated walls, in which was also the temple of Jupiter Capitolinus. This was also the name of a consecrated place on the Palatine Mount, where the augurs publicly performed their office. Off this *arx* the *faciales*, or heralds, gathered the grass used in the ceremony of leagues and treaties.

ARYTENOIDES, in anatomy, two cartilages which, with others, constitute the head of the

larynx. It is also applied to some muscles of the larynx.

ARYTENOIDEUS, in anatomy, one of the muscles serving to close the larynx.

ARYTHMUS, in medicine, the want of a just modulation in the pulse. It is opposed to eurythmus, a pulse modulated agreeably to nature.

ARZBERG, a market town in the circle of the Maine, district of Wunsiedel, Bavaria. The neighbouring hills yield iron, lime, and alum. The lime burned here is transported as manure to the Upper Palatinate and Bohemia. Seven miles east of Wunsiedel.

ARZILLA, an ancient maritime town of Africa, in the kingdom of Fez, S. S. W. of Tangiers. It was formerly a Roman colony; afterwards fell under the government of the Goths, and was next taken by the Mahomedans. Alphonso of Portugal, surnamed the African, took it by assault in 1472, and brought away the presumptive heir of the crown. After that prince came to the throne, he besieged it, in 1508, with 100,000 men. The Portuguese at length forsook it of their own accord. Long. 5° 40' W., lat. 35° 40' N.

AS. Usually called a conjunction, but according to some the Saxon article, *the, this or that*, which they say may always be substituted for it.

Besides that law which concerneth men *as men*; and that which belongs unto men *as they are men*, linked with others in some society: there is a third, which touches all several bodies politick, so far forth, *as one of them hath publick concerns with another.*

Hooker's Eccles. Polity.

PRINCE HEN. Dar'st thou be *as good as thy word now?*

FALST. Why, Hal, thou knowest, as thou art but a man, I dare; but *as thou art a prince, I fear thee, as I fear the roaring of the lion's whelp.*

Shakspeare. Henry IV.

When thou dost hear I am *as I have been*;

Approach me, and thou shalt be *as thou wast.* *Id.*

The cunningest mariners were so conquered by the storm, as they thought it best, with stricken sails, to yield to be governed by it. *Sidney.*

He had such a dexterous proclivity, *as his teachers were fain to restrain his forwardness.* *Wotton.*

The relations are so uncertain, *as they require a great deal of examination.* *Bacon.*

God shall by grace prevent sin so soon, *as to keep the soul in the virginity of its first innocence.* *South.*

Madam, were I *as you*, I'd take her counsel;

I'd speak my own distress.

A. Philip's Distrest Mother.

The objections that are raised against it *as a tragedy*, are as follow.

Gay's Preface to What D'ye Call it.

A simple idea is one uniform idea; *as sweet, bitter.*

Watts.

AS, among the ancient Romans, a weight, consisting of twelve ounces; being the same with libra, or the Roman pound. The word is derived from the Greek *as*, which in the Doric dialect is used for *ag*, one, q. d. an entire thing; though others will have it named *as*, quasi *as*, because made of brass.

AS, was also the name of a Roman coin, of different weight and different matter in different ages of the commonwealth. Under Numa Pompilius, according to Livy's story, the Roman money

was either of wood, leather, or shells. In the time of Tullus Hostilius, it was of brass; and called *as*, libra, libella, or pondo, because actually weighing a pound or twelve ounces. About 420 years after, the first Punic war having exhausted the treasury, they reduced the *as* to two ounces. In the second Punic war, Hannibal pressing very hard upon them, they reduced the *as* to half its weight, viz. to one ounce. And lastly, by the Papirian law, they took away half an ounce more, and consequently reduced the *as* to the diminutive weight of half an ounce; and it is generally thought that it continued the same during the commonwealth, and even till the reign of Vespasian. The *as*, therefore, was of four different weights in the commonwealth. Its original stamp was that of a sheep, ox, or sow; but from the time of the emperors, it had on one side a Janus with two faces, and on the reverse the rostrum or prow of a ship.

AS, being used to denote any integer or whole, signified in old English law the whole inheritance; whence *heres ex asse*, the heir to the whole estate.

ASA; **אסא**, Heb. i. e. a healer of sickness; king of Judah, succeeded his father Abijam, A. M. 2988. He abolished idolatry, restored the worship of the true God, and, with the assistance of Benhadad king of Syria, took several towns from the king of Israel. He died A. A. C. 917, and was succeeded by Jehoshaphat.

ASA, among naturalists, a word taken by modern authors from the lasar of the ancients, is applied to a gum very different from that anciently known by the name. The *asa* of the ancients was an odoriferous and fragrant gum; that of after ages had so little title to this epithet, that they distinguished it by an additional one, expressing its being of an offensive smell, as *ASAFETIDA*, which see. The Arabian writers describe two kinds of *asa*, the one of an offensive, the other of an aromatic smell.

ASA, or ASSA, in the materia medica, a name given to two very different substances, called *asa dulcis* and *asa fetida*.

ASAFETIDA, in chemistry, the common name of the *FERULA asafetida* of Linnæus, which see.

ASAHIEL; **אשהאל**, Heb. i. e. God has wrought; one of the sons of Zeruiah, David's sister, and the younger brother of Joab. He was one of David's thirty heroes, and remarkable for his swiftness. At the battle of Gibeon he pursued Abner with so much obstinacy, that he was obliged to kill him in self-defence, though it would appear with reluctance; 2 Sam. ii. 19—23.

ASAPII; **אספ**, Heb. i. e. gathering; the son of Berachiah, a Gershomite, and a famous musician and psalmist under David, king of Israel. Twelve of the Psalms bear his name; but it is doubted whether he was the author of them all, as some relate to later times.

ASAPPI, Sr. a city of Flintshire, in North Wales, situated in a pleasant valley at the confluence of the Elwy and Clwyd, twenty miles west of Chester, and 205 north-west of London.

As a bishopric, St. Asaph is of great antiquity, being founded about A. D. 560, by Kentigern, bishop of Glasgow. He began the church on the banks of the river Elwy, whence it is called by the Welsh, Llan Elwy, and in Latin, Elwensis. Kentigern returning into Scotland left St. Asaph his successor. The country was frequently in after times the seat of war between the English and the Welsh; and the records of the see are therefore very defective. This diocese does not contain any one whole county, but consists of part of Denbigh, Flint, Montgomery, and Merioneth shires, and a small part of Shropshire; wherein are 121 parishes, and 131 churches and chapels, most of which are in the immediate patronage of the bishop. It has but one archdeaconry, viz. that of St. Asaph, which is united to the bishopric, for the better maintenance thereof. The town, although situated in a rich valley, is a poor ill-built place; and the cathedral a plain building, 170 feet long, 108 broad, and 90 high. St. Asaph is contributory with Flint in sending one member to parliament. Market on Saturday. The deanery of St. Asaph is valued at £45. 11s. 5d., and is united to the vicarage of Henllan in the deanery of Rhos.

ASAPH, St. a native of North Wales, was descended of an ancient family, and flourished under Carentius king of the Britons, about A. D. 590. Being a monk in the convent of Llan Elwy, and the successor of its founder Kentigern, that establishment received his name ever after. He wrote the Ordinances of his church, and the Life of St. Kentigern. Bayle says he was the first who received unction from the pope.

ASAPHEIS, *ασαφεις*; from *a* negative, and *σαφης*, clear; persons who do not utter their words in a clear manner. The defect is occasioned, says Galen, 'either by some hurt which the organs of speech have contracted from a disorder of the nerves, or else by delirium.'

ASAPPE, or **AZAPES**, an order of soldiers in the Turkish army, whom they expose to the first shock of the enemy. The word is derived from the Turkish saph, which signifies rank, from whence they have formed asphaph, to range in battle. They travel on foot, and have no pay but the plunder they can get from the enemy.

ASAR, a gold coin current at Ormus in the Persian Gulf, worth 6s. 8d.

ASAROTA, *ασαρωτα*; from *a* and *σρωω*, I sweep; a kind of painted pavement in use before the invention of Mosaic work. The most celebrated was that at Pergamos, painted by Sesus, and exhibiting the appearance of crumbs, as if the floor had not been swept after dinner; whence, according to Pliny, the denomination. Perrault supposes it to have been a black kind of pavement of a spongy matter.

ASARUM, **ASARABACCA**, in botany, a genus of the monogynia order, and dodecandria class of plants. The calyx is trifold or quadrid, and rests on the germen; there is no corolla; the capsule is leathery and crowned. There are three species, viz. 1. *A. Canadense*, a native of Canada. 2. *A. Europæum*, growing naturally in some parts of England; and 3. *A. Virgin-*

cum, a native of America. The dried roots of this plant have been generally brought from the Levant; those of our own growth being supposed weaker. Both the roots and leaves have a nauseous, bitter, acrimonious, hot taste; their smell is strong, and not very disagreeable. The principal use of this plant among us is as a sternutatory; and the root of asarum is perhaps the strongest of all the vegetable errhines, white hellebore itself not excepted. The leaves are the principal ingredient in the pulvis sternutatorius, or pulvis asari compositus, of the shops.

ASASI, in botany, a name given by the people of Guinea to a tree, the leaves of which being boiled in water, and held to the mouth, cure the tooth-ache. In its form and manner of growing it resembles the laurel; the leaves are very hard and stiff, and grow alternately on the stalks; they have short pedicles, and the branches are blackish and rugged, but variegated with small reddish spangles, or scaly protuberances.

ASBAMEA, in ancient geography, a fountain of Cappadocia, near Tyana, sacred to Jupiter and to an oath. Though this fountain bubbled up as in a state of boiling, yet its water was cold; and never ran over, but fell back again.

ASBECK, a town of the bishopric of Munster, Westphalia, annexed to the possessions of the house of Salm in 1803. Here is a convent for noblemen's daughters. It is four miles south-east of Ahaus.

ASBEN, a considerable kingdom in the interior of Africa, between Fezzan and Cashna. The sultan is said by Hornemann to rank next to that of Bornou among the sovereigns of interior Africa. Zanfara and Guberare tributaries to him; he resides at Agades, and himself, with the greater part of his subjects, are Tuaricks of the tribe Kolluvi.

ASBESTOS, or **ASBESTUS**, in chemistry, from *a* privative, and *σβεννυμι*, I extinguish; a mineral consisting principally of silex and magnesia, with a small proportion of alumina, lime, and iron. It is a greenish brittle substance, unctuous to the touch, and somewhat elastic. Its fibres exposed to the violent heat of the blow-pipe, exhibit slight indications of fusion; though the parts, instead of running together, moulder away, and part fall down, while the rest seem to disappear before the current of the air. Ignition impairs the flexibility of asbestos in a slight degree. According to Herodotus, the Egyptians made a cloth of this substance, which they used for the purpose of wrapping up the bodies of the dead. Pliny says, he had seen napkins made of it, which, being taken foul from the table after a feast, were thrown into the fire, and by that means were better scoured than if they had been washed in water, &c. But he mentions its principal use being for the making of shrouds for royal funerals, so that the ashes might be preserved distinct from those of the wood, &c. whereof the funeral pile was composed. He calls the asbestos, *inventu rarum, textu difficillimum*. Bapt. Porta assures us, that in his time the spinning of asbestos was a thing known to every body at Venice; and Sig. Castagnatta, a superintendent of mines in Italy, is said

to have carried the manufacture to such perfection, that his asbestos was soft and tractable, much resembling lamb-skin dressed white: he could thicken and thin it at pleasure, and thus either make it into a very white skin or into paper. His method of preparing it is thus described: the stone is laid to soak in warm water; then opened and divided by the hands, that the earthy matter may be washed out. The abluition being several times repeated, the flax-like filaments are collected and dried; being most conveniently spun with an addition of flax. Two or three filaments of the asbestos are easily twisted along with the flaxen thread, if the operator's fingers are kept oiled. The cloth also, when woven, is best preserved by oil from breaking or wasting. On exposure to the fire the flax and the oil burn out, and the cloth remains pure and white. The shorter filaments which separate in washing the stone, may be made into paper in the common manner. Five varieties are described: 1. Common asbestos, which occurs in masses of fibres of a dull greenish color, and of a pearly lustre. It is scarcely flexible, and greatly denser than amianthus. Specific gravity, 2·7. Fuses with difficulty into a grayish-black scoria. It is composed of 63·9 silica, 16 magnesia, 12·8 lime, 6 oxide of iron, and 1·1 alumina, and is more abundant than amianthus, being usually found in serpentine, at Portsoy, the Isle of Anglesea, the Lizard in Cornwall, &c. It was found in the limestone of Glentilt, by Dr. McCulloch in a pasty state, but it soon hardened by exposure to the air. 2. Amianthus, which occurs in very long, fine, flexible, elastic fibres, is of a white, greenish, or reddish color. It has a silky or pearly lustre, and is slightly translucent; sectile; tough; specific gravity, from 1 to 2·3; it melts with difficulty before the blow-pipe into a white enamel, and consists of 59 silex, 25 magnesia, 9·5 lime, 3 alumina, and 2·25 oxide of iron. It is usually found in serpentine, in Savoy; in long and beautiful fibres, in Corsica; near Bareges in the Pyrenees; in Dauphny and St. Gothard; at St. Keverne, Cornwall; and at Portsoy, Scotland; in mica slate at Glenelg, Invernessshire, and near Durham. 3. Mountain leather, consisting not of parallel fibres, but interwoven and interlaced so as to become tough. When in very thin pieces it is called mountain paper. Its color is yellowish-white, and its touch meagre. It is found at Wanlockhead, in Lanarkshire. Its specific gravity uncertain. 4. Mountain cork, or elastic asbestos, is, like the preceding, of an interlaced fibrous texture; is opaque, has a meagre feel and appearance, not unlike common cork, and like it too, is somewhat elastic. It swims on water. Its colors are white, gray, and yellowish-brown. Receives an impression from the nail; very tough; cracks when handled, and melts with difficulty before the blow-pipe. Specific gravity, from 0·68 to 0·99. It is composed of silica 62, carbonate of lime 12, carbonate of magnesia 23, alumina 2·8, oxide of iron 3. 5. Mountain wood, or ligniform asbestos, is usually massive, of a brown color, and having the aspect of wood. Internal lustre, glimmering. Soft, sectile, and tough; opaque; feels meagre; fusible into a black slag. Specific

gravity 2·0. It is found in the Tyrol; in Dauphny; and in Scotland: and has lately been employed by Aldini as a protecting dress for firemen.

ASCALON, an ancient city, one of the five satrapies or principalities of the Philistines; situated on the Mediterranean, forty-three miles south-west of Jerusalem, between Azotus on the north, and Gaza on the south. It was the birth-place of Herod the Great, thence surnamed Ascalonites, and was famous for its escallions, which take their name from this town. It is now called Scalona.

ASCANII, in entomology, a species of curculio, of shape cylindrical, color black, and bluish on the sides.

ASCANIUS, the son of Æneas and Creusa, succeeded his father in the kingdom of the Latins, and defeated Mezentius king of the Tuscans, who had refused to conclude a peace with him. He founded Alba Longa; and died about A. A. C. 1139, after reigning thirty-eight years.

ASCANTUS, in entomology, a species of papilio. Color black, above and beneath, with a white band; posterior wings reddish; it is a native of sil.

ASCARIS, *ασκαρις*; from *ασκειν*, to move about; in zoology, an intestinal worm so called from its troublesome motion. In the Linnæan system it is a genus of the class vermes, order intestina; thus generically characterised. Body round, elastic, and tapering towards each extremity; head with three vesicles; tail obtuse or subulate; intestines spiral, milk-white, and pellucid. Upwards of eighty species have been enumerated, generally deriving their name from the animal they chiefly infest: for the intestinal canal of most animals is affected by some species.

The species of *Ascaris* described by Gmelin are arranged in the following order:

Infesting man, and the mammalia.—*Vermicularis*, *lumbricoides*;—*vespertilionis*, in the long-eared bat:—*Phocæ*, *bifida*, *canis*, *visceralis*, *lupi*, *vulpis*, *leonis*, *tigridis*, *felis*, *cati*, *martis*, *bronchialis*, *renalis*, *mephitidis*, *gulonis*, *talpæ*, *muris*, *hirci*, *vituli*, *equi*, *suis*, *apri*.

Infesting birds.—*Aquilæ*, *albicillæ*, *buteonis*, *milvi*, *subuteonis*, *hermaphrodita*, *cornicis*, *coraciæ*, *cygni*, *anatis*, *fuligulæ*, *lari*, *ciconiæ tardæ*, *papillosa*, *gallopavonis*, *galli*, *gallinæ*, *phasiani*, *tetraonis*, *columbæ*, *alaudæ*, *sturni*, *turdi*.

Infesting reptiles.—*Testudinis*, *lacertæ*, *bufonis*, *pulmonalis*, *rubetræ*, *trachealis*, *ranæ*, *intestinalis*, *dyspnoos*, *insons*.

Infesting fishes.—*Anguillæ*, *marina*, *blennii*, *rhombi*, *percæ*, *globoicola*, *lacustris*, *siluri*, *fari-onis*, *truttæ*, *maraenæ*, *acus*, *halecis*, *argentinæ*, *gobionis*, *rajæ*, *squali*, *lophii*.

Infesting worms.—*Lumbrici*.

We can only describe the two principally infesting man.

1. *A. lumbricoides*, is about the same length with the *lumbricus terrestris*, or common earth-worm; but it wants the protuberant ring towards the middle of the body, the only mark by which they can be properly distinguished. The body is cylindrical, and subulated at each extremity; but the tail is somewhat triangular. The *lumbricoides* is the worm which is most commonly

found in the human intestines. It is viviparous, and produces vast numbers. 2. *A. vermicularis*, with faint annular rugæ and the mouth transverse, is about a quarter of an inch long, and thicker at one end than the other. It is found in boggy places, in the roots of putrid plants, and very frequently in the rectum of children and horses. It emaciates children greatly, and is sometimes vomited up. See **MEDICINE** and **WORMS**.

ASCAROIDES, a species of cucullian found in the stomach of the silurus glanus: the head is orbicular; tail round, short, and pointed with two spicules.

ASCEND,
ASCEN'DANT, *n.* & *adj.* } *Ascendo*, from *ad*,
ASCEN'DANCY, } and *scendo*, to climb.
ASCEN'SION, } To mount upwards,
ASCEN'SIVE, } to mount, to
ASCEN'T. } acquire an elevation,
a superiority.

Eneas and vnilly Dido baith tuay,
To forest grathis in hunting forth he wend
To marrow als fast as Titan dois *ascend*,
And ouer the warld gan his bemes spred.
Douglas Eneados, bk. iv. p. 104.

Northumberland, thou ladder wherewithal
The mounting Bolingbroke *ascends* the throne.
Shakspeare. *Richard II.* act v. sc. 2.
Over head up grew

Insuperable height of loftiest shade,
Cedar and pine and fir and branching palm,
A sylvan scene; and as the ranks *ascend*,
Shade above shade, a woody theatre
Of steepest view.

Milton's Paradise Lost, book iv. line 131.

Then, rising from his grave,
Spoil'd principalities and pow'rs; triumph'd,
In open shew; and, with *ascension* bright,
Captivity led captive through the air. *Id.*

Thus look'd Elisha, when to mount on high,
His master took the chariot of the sky;
The fiery pomp, *ascending*, left the view;
The prophet gazed, and wished to follow too.
Parnell.

In his blest life

I see the path, and in his death the price,
And in his great *ascend*, the proof supreme
Of immortality. *Young.*

Themistocles now entered. At his look,
Which carried strange *ascendancy*, a spell
Controlling nature, was the youth abash'd.
Glover's Athenaid, book xiv.

Thus, having passed the rocks in safety, we found
the rest of the coast rise from the sea with a smooth
and easy *ascend*; and, floating at ease upon a gentle
tide, we soon reached the sands with our feet.

Hawkesworth's Telemachus.

Their tribes adjusted, clean'd their vig'rous wings,
And many a circle, many a short essay,
Wheel'd round and round: in congregation full,
The figur'd flight *ascends*. *Thomson.*

Fire fill'd his eyes;

Turning, he bade the multitude without
Ascend the rampart; they his voice obey'd,
Part climb'd the wall, part pour'd into the gate.
Couper's Liad, book xii.

ASCENDANT, in astrology, denotes the horoscope, or the degree of the ecliptic which rises upon the horizon at the time of the birth of any one. This is supposed to have an influence on

the person's life and fortune, by giving him a bent and propensity to one thing more than another. In the jargon of Astrologers, it is also called the first house, the angle of the east, or oriental angle, and the significator of life.—Such a planet ruled in his ascendant; Jupiter was in his ascendant, &c. Hence the word is also used in a moral sense, for a certain superiority which one man has over another from some unknown cause.

ASCENDANTS, in law, are opposed to descendants in succession; i. e. when a father succeeds his son, or an uncle his nephew, &c. heritage is said to ascend, or go to ascendants.

ASCENDING, in astronomy, is said of such stars as are rising above the horizon in any parallel of the equator. And thus likewise,

ASCENDING LATITUDE, is the latitude of a planet, when going towards the north pole.

ASCENDING NODE, is that point of a planet's orbit, wherein it passes the ecliptic, to proceed northward. This is otherwise called the northern node, and represented by this character Ω .

ASCENDING SIGNS, among astrologers, are those which are upon their ascent, or rise, from the nadir, or lowest part of the heavens, to the zenith, or highest.

ASCENDING VESSELS, in anatomy, those which carry the blood upwards; as the aorta ascendens. See **ANATOMY**.

ASCENSION, an island of the Atlantic, in S. lat. $8^{\circ} 8'$, and W. long. $14^{\circ} 28'$, lately taken possession of by Great Britain, with a view to the better defence of St. Helena. Prior to this it was wholly uninhabited. The island, which has an excellent harbour, is ten miles in length from north-west to south-east, and from five to six in breadth. A flag officer resides here, on the single spot which presents a vegetable mould, in the south-east corner of the island: and homeward bound vessels from the Cape of Good Hope and the East Indies call here, under certain regulations. Plenty of fish and sea-fowl are found on the shores, and some fine turtle. **ASCENSION** is evidently a volcanic production; at a distance it has the appearance of an immense sugar-loaf arising out of the sea, but on approaching it the top is broken into various barren peaks.

ASCENSION, in astronomy, is either right or oblique. Right ascension of the sun, or a star, is that degree of the equinoctial, counted from Aries, which rises with the sun or star in a right sphere. Oblique ascension is an arch of the equator intercepted between the first point of Aries and that point of the equator which rises together with a star in an oblique sphere.

To find the right ascension of the sun, stars, &c. by trigonometry, say, as the radius is to the cosine of the sun's greatest declination, or obliquity of the ecliptic; so is the tangent of the sun's or star's longitude to the tangent of the right ascension. To find the ascensional difference, you must have the latitude of the place, and the sun's declination given: then say, as the radius is to the tangent of the latitude; so is the tangent of the sun's declination to the sine of the ascensional difference sought. This, converted into time, shows how much he rises before, or sets after, six o'clock; by subtracting which from the right ascension, when the sun is

in the northern signs, and adding it when he is in the southern ones, you will find the oblique ascension.

ASCENSION DAY; the day on which the ascension of our Saviour is commemorated, commonly called Holy Thursday; the Thursday but one before Whitsuntide.

ASCENSIONAL DIFFERENCE, is the difference between the right and oblique ascension of the same point to the surface of the sphere. The ascensional difference of the sun, converted into time, is just so much as he rises before or after six o'clock.

ASCENSIONIS, in ichthyology, a species of perca, found about Ascension Island; color reddish above, whitish beneath, the tail bifurcated.

ASCENT, in logic, denotes a kind of argument, wherein we rise from particulars to universals: as, when we say, this man is an animal, and that man is an animal, and the other man, &c. therefore every man is an animal.

ASCENT, in physics, implies the motion of a body upwards, or the continual recess of a body from the earth. The Peripatetics attributed the spontaneous ascent of bodies to a principle of levity inherent in them. The moderns deny spontaneous levity; and show, that whatever ascends, does it in virtue of some external impulse or extrusion. Thus smoke and other rare bodies ascend in the atmosphere; and oil, light woods, &c. in water; not by any internal principle of levity, but by the superior gravity or tendency downwards of the parts of the medium where they are. The ascent of light bodies in heavy mediums is produced after the same manner as the ascent of the lighter scale of a balance. It is not that such scale has an internal principle whereby it immediately tends upwards; but it is impelled upwards by the preponderancy of the other scale; the excess of the weight of the one having the same effect, by augmenting its impetus downwards, as so much real levity in the other; because the tendencies mutually oppose each other, and that action and reaction are always equal.

ASCERTAIN. *v.* Old Fr. *ascertener*, from

ASCERTAINMENT. *v.* and *certum*, *cerno*; gr. *scizo*, to distinguish, to separate. To be sure or certain, to discover the truth, to bring inquiries to a satisfactory result.

The divine law both *ascertaineth* the truth, and suppleth unto us the want of other laws. *Hooker.*

Money differs from uncoined silver in this, that the quantity of silver in each piece is *ascertained* by the stamp. *Locke.*

Right judgment of myself may give me the other certainty; that is, *ascertain* me, that I am in the number of God's children.

Hinmond's Practical Catechism.

This makes us act with a repose of mind, and wonderful tranquillity; because it *ascertains* us of the goodness of our work. *Dryden's Dufresnoy.*

He tells us that the positive *ascertainment* of its limits, and its security from invasion, were among the causes for which civil society itself has been instituted.

Barke in the Revolution in France.

The characters of great men, which are always mysterious while they live, are *ascertained* by the faithful historian, and sooner or later receive their wages of fame or infamy, according to their true deserts. *Cowper's Letters.*

ASCESIS, from the verb *ασκειν*, used by the ancients in speaking of the sports and combats of the athlete, properly denotes exercise of the body. It is also used by philosophers, to denote an exercise conducive to virtue, or to the acquiring a greater degree of virtue. This is particularly denominated the philosophical *acesis*, because practised chiefly by philosophers, who make a more peculiar profession of improving themselves in virtue; on the model of which the ancient Christians introduced a religious *acesis*.

ASCETERIUM, in ecclesiastical writers, a monastery, or place set apart for the exercises of religion. The word is formed from *acesis*, exercise; or *ascetra*, one who performs exercise. Originally it signified a place where the athlete or gladiators performed their exercise.

ASCETICK, *n. & adj.* } *ΑΣΚΗΤΙΚΟΣ, ασκειω*
ASCETICISM. } to exercise. Applied primarily to those who exercised themselves in religious contemplations and for this purpose separated themselves from the world.

None lived such long lives as monks and hermits; sequestered from plenty, to a constant *ascetick* course of the severest abstinence and devotion. *South.*

I am far from commending those *asceticks*, that out of a pretence of keeping themselves unspotted from the world, take up their quarters in deserts. *Norris.*

He that preaches to man, should understand what is in man; and that skill can scarce be attained by an *ascetick* in his solitudes. *Atterbury.*

The truth is we have seen, and yet do see, religious societies whose religious doctrines are so little serviceable to civil government that they can prosper only on the ruin and destruction of it. Such are those which teach the sanctity of celibacy and *asceticism*.

Warburton's Alliance, book ii.

ASCETICS, persons in the primitive times who devoted themselves to the exercises of piety, in a retired life, and particularly to prayer, abstinence, and mortification. Afterwards this title was bestowed upon the monks, especially such of them as lived in solitude. This is also a title of several books of spiritual exercises, as the *Ascetics*, or devout exercises of St. Basil, archbishop of Cæsarea in Cappadocia, &c.

ASCHAFFENBURG, a town and district of Germany, on the Maine, formerly belonging to the elector of Mentz, who had a palace there, but now included in the kingdom of Bavaria. It is memorable for being the place where king George II. took up his quarters the night before the battle of Dettingen. It stands on an eminence, in a delightful country, and is of a quadrangular form. The number of inhabitants in the town is about 6400; they received a considerable augmentation by the emigrations from Mentz, on the occupancy of that city by the French in 1798. It has four churches, and a foundation called Insignis Collegiata, the capuchin monastery; the ancient Jesuits' college is now a lyceum or public school. Aschaffenburg was taken by the French in July 1796, and again in 1800. The rivulet of this name here discharges itself into the Maine. This town is eighteen miles south-east of Frankfort, and forty east of Mentz.

ASCHAM (Roger), was born at Kirby-Wiske, near North Allerton, in Yorkshire, in the year

1516. His father was steward to the noble family of Scroop. Roger was educated in the family of Sir Anthony Wingfield, who, about the year 1530, sent him to St. John's College, Cambridge, where he was soon distinguished for his application and abilities. He took his degree of A. B. at the age of eighteen; was soon after elected fellow of his college; and in 1536 proceeded A. M. In 1544 he was chosen university orator; and, in 1548, was sent for to court to instruct the lady Elizabeth (afterwards queen) in the learned languages. In 1550 he attended Sir Richard Morysine, as secretary, on his embassy to the emperor Charles V., at whose court he continued three years, and in the mean time was appointed Latin secretary to Edward VI. But upon the death of that prince, he lost his preferment and all his hopes, being professedly of the reformed religion; yet, contrary to his expectations, he was soon after, by the interest of his friend lord Paget, made Latin secretary to the king and queen. In June 1554 he married Mrs. Margaret How, with whom he had a considerable fortune. It is very remarkable, that, though Mr. Ascham was known to be a protestant, he continued in favor, not only with the ministry of those times, but with queen Mary herself. Upon the accession of Elizabeth, he was confirmed in his post of Latin secretary, and resumed his employment as preceptor to her majesty in the learned languages. He died in 1568, not rich, but much regretted, especially by the queen. He wrote, 1. *Toxophilus*. The scholæ or partitions of shooting, contained in two books, written by Roger Ascham, 1544, and now newly perused. Pleasaut for all gentlemen and yeomen of England, &c. Lond. 1571. This treatise was dedicated to Henry VIII. who settled a pension of £10 per annum upon the author. It is said to have been written principally to promote the improvement of English prose. 2. A Report of the affairs and state of Germany, and the emperor Charles his court, &c. 4to. 3. The Schoolmaster: first printed in 1573, 4to. Mr. Upton published an edition with notes, in 1711. It has uncommon merit. 4. Latin epistles; first published by Mr. Grant in 1576; the best edition is that of Oxford in 1703. These are much admired on account of the style, and esteemed almost the only classical work of the kind written by an Englishman. 5. *Apologia contra Missam*, 1577, 8vo. His works were collected and published by Bennet, in one volume, 4to. 1769, with a life, by Dr. Johnson.

ASCHERSLEBEN, the chief town of a district in the principality of Halberstadt, Prussia, is seated between the Eine and Wipper, sixteen miles south-east of Halberstadt. It was formerly a Hanse town, and the capital of the principality of Ascania, but was annexed to Halberstadt in the year 1320. Here are manufactures of frieze and flannel; and the suburbs, one of which is called the New Town, are well built. Inhabitants about 8000; and here are a Lutheran and Calvinist school; four churches, one of which, called the Market church, is possessed by the two sects in common. The castle is in ruins.

ASCHILLIUS, king of the Dacians, one of

those monarchs, who is said to have assisted king Arthur in his wars.

ASCIA, in antiquity, an instrument supposed to be of the axe kind, used in the fabric of the Roman tombs, and frequently represented on them.

ASCIA, in surgery, is a kind of bandage, somewhat oblique or crooked; whose form and use are described by Sculteus, in his *Arman. Chirug.*

ASCIBURGIUM, in ancient geography, supposed to be one of the fifty citadels built on the Rhine, is mentioned by Tacitus, who adds, that some imagine it was built by Ulysses. Here was a Roman camp and a garrison. To its situation on the banks of the Rhine answers a small hamlet, now called Asburg.

ASCIDIA, a genus of animals belonging to the order of vermes mollusca. The body is cylindrical, and fixed to a shell, rock, &c. It has two apertures, one on the summit, the other lower, forming a sheath. These creatures have the power of contracting or dilating themselves; most of them are sessile. Gmelin enumerates the following species: *papillosa*, *gelatinosa*, *intestinalis*, *quadridentata*, *rustica*, *echinata*, *mentula*, *venosa*, *prunum*, *conchilega*, *parallelogramma*, *virginea*, *canina*, *patula*, *aspersa*, *scabra*, *orbicularis*, *corrugata*, *lepadiformis*, *complanata*, *tuberculum*, *villosa*, *clavata*, *pedunculata*, *mammillaris*, *globularis*, *pusca*, *gelatina*, *crystallina*, *octodentata*, *patelliformis*, *pyura*, *aurantium*, *globularis*.

ASCINDOE, in botany, a name given by the people of Guinea to a shrub, which they use in medicine, boiling it in water, and giving the decoction in gonorrhœas, and the like complaints. Petiver has named it the prickly Guinea shrub. The thorns on the large branches are very strong.

ASCITÆ; from *ασκος*, a bag or bottle; in antiquity, a sect of Montanists, who appeared in the second century; so named, because they introduced a kind of Bacchanals into their assemblies, who danced round a bag or skin blown up; saying, they were those new bottles filled with new wine, whereof our Saviour makes mention, *Matth. ix. 17.*—They are sometimes also called *Ascodrogite*.

ASCITES; from *ασκος*, a water bottle; in medicine, dropsy of the belly; so called from the protuberance of the belly in that disease resembling a bottle. It is divided into two species, *ascites abdominalis*, in which there is a regular and equal intumescence of the abdomen; and *ascites saccatus*, when the ovaries, &c. are the seat of the disease, and the swelling, at least in the beginning, is partial. The cure is difficult, since the disease is often only the symptom of a decaying constitution; evacuations are the chief palliatives, and paracentesis (*παρακέντησις*, to perforate), or tapping, relieves for a time, and, in some cases, permanently. See *MEDICINE*.

ASCLEPIA, a festival of Æsculapius the god of physic, observed particularly at Epidaurus, where it was attended with a contest between the poets and musicians, whence it was likewise called *Ἱερός ἀγών*, the sacred contention.

ASCLEPIAD, in ancient poetry, a verse composed of four feet, the first of which is a spondee,

the second and third choriambuses, and the last a pyrrhicius : or of four feet and a cæsura, the first a spondee, the second a dactyl, after which comes the cæsura, then the two dactyls ; as

Macēnās ātāvīs | ēdīte | rēgībūs.
O ēt | præsīdīum | dūlcē dējūs mēūm.

ASCLEPIADES, a celebrated physician among the ancients, was a native of Prusa, in Bithynia, and practised physic at Rome, about A. C. 96. He was the head of a new sect ; and, by prescribing wine and cold water in the cure of the sick, acquired a very great reputation. He wrote several books, frequently mentioned by Galen, Celsus, and Pliny ; but they are now lost.

ASCLEPIADES, a famous physician under Adrian, of the same city with the former. He wrote on the composition of medicines, both internal and external.

ASCLEPIAS, SWALLOW-WORT, in botany, a genus of the digynia order, and pentandria class of plants ; ranking in the natural method under the thirtieth order, contortæ. The generic character is taken from five oval, concave, hornlike nectaria, which are found in the flower. There are nineteen species, of which the following are the most remarkable, viz. 1. A. alba, or common swallow-wort. 2. A. curassavica, or bastard ipecacuanha, a native of the warm parts of America. 3. A. Syriaca, or greater Syrian dogsbane. The root of the first species is used in medicine. Though reckoned by botanists a species of dogsbane, it may be distinguished from all the poisonous sorts, by its yielding a limpid juice. The root has a strong smell, especially when fresh, approaching to that of valerian, or nard ; the taste is at first sweetish and aromatic, but soon becomes bitterish, subacid and nauseous. It is esteemed sudorific, diuretic, and emmenagogue. It is also frequently employed by the French and German physicians as an alexipharmic, and sometimes as a succedaneum to contrayerva, whence it has received the name of *contrayerva Germanorum*.

ASCLEPIODORUS, a British prince who flourished in the third century. He killed Alecutus the Roman general, who had slain the celebrated Carausius ; and was elected king of the Britons, A. D. 232. He besieged and took London from the Romans, and threw Livius Gallus the Roman general into a brook, which thence received the name of Gallbrook, since changed into Wallbrook. He was at last slain by Coilus II. king of the Britons, A. D. 260.

ASCOBOLUS, in botany; from *ασκος*, a skin, and *βολος*, a cast; so called because the seeds are thrown out with elasticity; class, cryptogamia fungi. Its essential characters are, receptacle, fleshy, hemispherical; seed-cases oblong, discharged elastically; seeds moist, about eight. 1. A. furfuraceous, powdery ascobolus. Common on cow-dung late in autumn. 2. A. carneus, flesh-colored ascobolus; found on dung in woods, rare. 3. A. glaber, smooth brown ascobolus, on cow-dung in autumn. 4. A. immersus, sunk ascobolus; in the same situations, almost entirely sunk in the dung, so that the seed-cases only are prominent.

ASCODUTÆ, in church history, a sect of Christians, in the second century, who rejected all use of symbols and sacraments, on this principle, that incorporeal things cannot be communicated by things corporeal, nor divine mysteries by any thing visible.

ASCOGEPHYRUS, in writers of the middle age, a bridge supported on bags made of leather, or bullocks' hides. Such bridges appear to have been in use among the ancients, and to have given the denomination to a tribe of Arabs, hence called Ascite.

ASCOLI, anciently called Asculum Picenum, a pretty large and populous town of Italy, in the marquise of Ancona, and territory of the church. It is a bishop's see, and seated on a mountain between the rivers Tronto and Castellano, forty-eight miles south of Ancona.

ASCOLI DI SATRIANO, formerly called Asculum Apulum, and Asculum Picenum, a city of Naples, in the Capitanata, with a bishop's see under the archbishop of Benevento, seventy miles east of Naples, and thirty west of Manfredonia.

ASCOLIA, in Grecian antiquity, a festival celebrated by the Athenian husbandmen in honor of Bacchus, to whom they sacrificed a he-goat, and made a foot-ball of his skin, because that animal destroys the vines. See *Virgil, Georg.* ii. 380.

ASCONIUS PEDIANUS, an ancient grammarian of Padua; and, according to Servius, an acquaintance of Virgil's. He wrote commentaries on Cicero's Orations, fragments of which are published in Cicero's works.

ASCOPHORA, in botany; from *ασκος*, bladder, and *φορω*, to bear; class cryptogamia fungi. Its essential characters are, thread-shaped, terminating in a slightly inflated head. There is but one species, viz. A. perennis, perennial bladder-mould.

ASCORCA, a town and valley of Majorca, six leagues from Palma, principally known by its famous sanctuary, Nuestra Senora de Lluch. This is a large and beautiful edifice, containing an image of the virgin, said to have been miraculously discovered on the spot in 1238. The number of persons connected with this establishment is 400. The canons are proprietors of the valley, which abounds in wine and olives.

ASCOUGH (William), L. L. D. appointed bishop of Salisbury in 1438, and soon after confessor to king Henry VI. He was seized by the famous rebel Jack Cade on the 28th June, 1450, who, after plundering his carriage, fell upon him the next day, while he was officiating at the altar, in Edington, Lincolnshire, and dragging him to a neighbouring hill dashed out his brains.

ASCRA, a village of ancient Greece near Mount Helicon, the birth place of the poet Hesiod.

ASCRIBE,
ASCRIBABLE,
ASCRIPTION,
ASCRIPTIOUS } Lat. *ad scribo*, to write to.
Primarily to practice the art
of writing on any substance
and with any instrument.
Subsequently to charge, attribute, or place to the account of any one, whether in writing or otherwise.

Oh! ye traitours and maintainers of madness,
Unto your folly I *ascribe* all my paine;
Ye haue me deprived of ioy and gladnesse,
So dealing with my lord and soueraine.

Chaucer. Lamentation of Marie Magdalene,
fol. 319. ch. iv.

True wisdom teaches to distinguish God's actions,
and to *ascribe* them to the right causes.

Hall's Contemplations.

Ascribe thou nation, every favour'd tribe,
Excelling greatness to the Lord *ascribe*;
The Lord, the rock on whom we safely trust,
Whose work is perfect, and whose ways are just.

Parnell. The Gift of Poetry.

The cause of his banishment is unknown; because
he was unwilling to provoke the emperor, by *ascribing*
it to any other reason than what was pretended.

Dryden.

To this we may justly *ascribe* those jealousies and
encroachments which render mankind uneasy to one
another.

Rogers.

These perfections must be somewhere; and there-
fore may much better be *ascribed* to God, in whom
we suppose all other perfections to meet, than to any
thing else.

Tillotson.

The greater part have been forward to reject it
upon a mistaken persuasion; that those phenomena
are the effects of nature's abhorrence of a vacuum,
which seem to be more fitly *ascribable* to the weight
and spring of the air.

Boyle.

Sometimes we *ascribe* to ourselves the merit of good
qualities, which if justly considered should cover us
with shame.

Craig.

Holiness is *ascribed* to the pope; majesty to kings;
serenity or mildness to princes; excellence or perfec-
tion to ambassadors; grace to archbishops; honor to
peers.

Addison.

The innocent gambols of a few otters, have been
known to occasion those yells which the vulgar of this
country mistake for laughing or crying, and *ascribe* to
a certain goblin, who is supposed to dwell in the
waters, and to take delight in drowning the bewildered
traveller.

Beattie.

ASCRIPTI, or ADSCRIPTI, in antiquity, those
who entered their names in the colonies, and became
coloni.

ASCRIPITII, or ADSCRIPITII, in ancient
barbarous customs, a kind of villains, who, coming
from abroad, settled in the lands of some
new lord, and became so annexed to the lands
that they might be transferred and sold with
them. *Ascripti* is sometimes also used in
speaking of aliens or foreigners newly admitted
to the freedom of a city or country.

ASCRIPITII was used in the military laws for
the recruits to supply the legions, called also
ACCENSI, which see.

ASCRIVIUM, in ancient geography, a town
of Dalmatia, on the Sinus Rhizicus, now called
Cattaro, in Venetian Dalmatia.

ASCULUM APULUM, and PICENUM. See
ASCOLI.

ASCUS, in natural history, the pouch or bag
of the opossum, for receiving its young. It is
a skinny bag, separate from the rest of the body,
but adhering by a membrane to the bottom of
the belly.

ASCYRUM, PETER'S WORT, in botany, a genus
of the polyandria order, and the polyadelphia
class of plants, ranking in the natural method
under the twentieth order, rotacææ: CAL. four
leaves: COR. four petals; the filaments are nu-

merous, and divided into four bundles. There
are three species: 1. *A. crux andrea*; 2. *A.*
hypericoides; 3. *A. villosum*; all natives of the
West-Indies, or America.

ASDRUBAL, the name of several Carthaginian
generals. See CARTHAGE.

ASEKAI, ASEKI, the name which the Turkish
emperors give to their favorite sultan, generally
those who have brought forth sons. These are
greatly distinguished above others in their apart-
ments, attendants, pensions, and honors. They
have sometimes shared the government. The
sultana who first presents the emperor with a
male child is reckoned the chief favorite, and
is called buyuk asek.

ASELE-LAPPMARK, a division of Swedish
Lapland, contains the large parish of Asele, sixty
English miles in length. In the town of this
name there is a church, erected in 1648. Here
is also a school, established in 1730, where six
children of Laplanders are educated at the ex-
pense of the government. This place is moreover
the seat of a court of justice, and has a yearly
fair. The inhabitants trade in rein-deer
skins, flesh, butter, cheese, fowls, fish, and furs.
Eighty-five miles west of Umea. Long. 17° 4
E., lat. 64° 12' N.

ASELLA, in entomology, a species of pha-
læna, of the bombyx family, found in Germany.
wings brownish without spots.

ASELLI, in astronomy, two fixed stars of the
fourth magnitude, in the constellation Cancer.

ASELLI or ASELLIUS (Caspar), an Italian
anatomist of the seventeenth century, who dis-
tinguished himself by discovering the lacteal
vessels. He was born at Cremona, and studied
medicine, and became professor of anatomy in
the university of Pavia. Aselli first observed
the lacteals in dissecting a living dog. His
investigations were published after his death at
Milan in 1627.

ASELLINA, in zoology, a species of Lernæa,
having the body lunated, and the thorax heart-
shaped. Found fixed on the gills of some fishes.

ASELLUS, in entomology, a species of the
oniscus genus; of an oval shape, with an obtuse
tail, furnished with two styles. It delights in
moist places, under stones, in damp and rotten
wood, &c. The young are contained in a four-
valved receptacle, under the abdomen of the
female. This is commonly known by the name
of the wood louse.

ASELLUS, in conchology, a species of chiton,
most frequently found adhering to the mytilus
modiolus. The shell consists of eight valves, very
black, with a yellow spot on each valve, convex
above; also a species of cypræa, common about
the Madeira islands. It is white, with three
brown bands bordered with yellow or red.

ASENATH, the daughter of Potipherah, priest
or prince of On, and wife of Joseph, prime mi-
nister to Pharaoh king of Egypt. See Genesis
xli. 45.

ASEPTA; in medicine, from *a* negative, and
σηπω, to putrefy; signifies any thing unputrefied,
or uncoacted.

ASGILL (John), a humorous writer, bred to
the law, which he practised in Ireland with great
success. He was there elected a member of the

house of commons, but was expelled for writing a Treatise on the Possibility of avoiding Death. Being afterwards chosen member for Bramber in Sussex, he was on the same account expelled the parliament of England. After this, he continued thirty years a prisoner in the Mint, Fleet, and King's Bench; during which time he published a multitude of political pamphlets. He died in the King's Bench in 1738, aged above eighty.

ASH', *n* .& *v*. } Ang.-Sax. Asia, asce; dust,
ASH'Y, } ashes. The remains of any
ASH'TUB, } substance which has been
ASH'YPALE. } burnt.

Ye Trojan *ashes*, and last flames of mine,
I cal in witness, that at your last fall,
I fled no stroke of any Grekish sword. *Surrey*.

Poor key-cold figure of a holy king!
Pale *ashes* of the house of Lancaster!
Thou bloodless remnant of that royal blood!

Shakespeare.

So that lone bird in fruitful Arabie,
When now her strength and waning life decays,
Upon some aerie rock or mountain high,
In spiced bed, fired by near Phœbus rays,
Herself and all her crooked age consumes,
Straight from the *ashes*, and those rich perfumes,
A new-born phoenix flies, and widow'd place resumes.

Fletcher's Purple Island.

Pornicus next him pac'd, a meagre wight,
Whose leaden eyes sunk deep in swimming head,
And joyless look, like some pale *ashy* sprite,
Seem'd as he were dying, or now dead. *Id*.

His *ashy* coat that bore a gloss so fair,
So often kiss'd of the enamour'd air,
Worn all to rags, and fretted so with rust,
That with his feet he trod it into dust.

Drayton's Poems. The Owl.

Ah! leave me not for Grecian dogs to tear;
The common rites of sepulture bestow,
To soothe a father's and a mother's woe;
Let their large gifts procure an urn at least,
And Hector's *ashes* in his country rest. *Pope*.

To great Laertes I bequeath
A task of grief, his ornaments of death;
Lest, when the fates his royal *ashes* claim,
The Grecian matrons taint my spotless name. *Id*.

ASH, } Of doubtful etymology. Todd's
ASH'EX. } Johnson gives are, a tree.

There sawe I eke the fresh hauthorne,
In white motley that so swote doth smell,

Asshe, firre, and oke with many a young acorn,
And many a tree mo than I can tell.

Chaucer. The Complaint of the Black Knight,
f. 271. c. 1.

For whan we may not don, than wol we speken,
Yet in our *ashen* cold is fire yreken.

Id. The Reve's Prologue, v. i. p. 153.

As from some far seen mountain's airy crown,
Subdu'd by steel a tall *ash* tumbles down,
And soils its verdant tresses on the ground;
So falls the youth; his arms the fall resound.

Pope. Iliad,

Then exercise thy sturdy steers to plough
Betwixt thy vines, and teach the feeble row
To mount on reeds, and wands, and upward led
On *ashy* poles, to raise their forky head.

Dryden's Virgil, Georg. ii.

ASH (John), L.L.D. a baptist minister, born in 1724; was at one period coadjutor with Dr. Caleb Evans in the management of the Bristol academy, and subsequently pastor of a congregation at Pershore, where he died in 1779. Besides several religious publications, he was the author of a Dictionary of the English language; and an Introduction to Lowth's Grammar, which has passed through a great number of editions.

ASHA'ME, } Found in all the Northern
ASHA'MED. } languages. It has perhaps a
literal affinity to *αἰσχρῶν*, to blush, to redden;
although, according to our usage, it means the
feeling that occasions the blush; to feel shame.
See SHAME.

And whanne he seide these thingis alle his adner-
saries weren *ashamed*: and al the puple joyede in alle
thingis: that weren gloriously don of him.

Wiclif. Luk. c. 13.

Some men seem to be *ashamed* of those things
which would be their glory, whilst others glory in
their *shame*.

Mason on Self-knowledge.

Ye only can engage the servile brood
Of levity and lust, who all their days
Ashamed of truth and liberty have woo'd,
And hug'd the chain that glittering on their gaze,
Seems to outshine the pomp of heaven's empyreal
blaze. *Beattie's Minstrel*.

The modest speaker is *asham'd* and griev'd
T'engross a moment's notice, and yet begs,
Begg a propitious ear for his poor thoughts,
However trivial all that he conceives.

Couper's Tusk.

A S H A N T E E.

ASHANTEE, a native kingdom of the Gold Coast of Africa, and an important power in the neighbourhood of our settlements on the western coast. It appears to be far superior in civilisation, commerce, and general resources, to any known African state. The predominance of this power indeed has, within the last ten years, entirely altered the political aspect of the coast. It is well known that our late excellent and intrepid commander on this coast, and at Sierra Leone (Sir Charles MacCarthy), lost his life in a fruitless attempt to drive back a considerable force of the Ashantees from the Gold Coast. A late war between the Fantees and the king of Ashantee first brought the latter country to the knowledge of Europeans. The Fantees had long plundered the Ashantee merchants, and treated

with contempt the remonstrances of that kingdom, till at last the Ashantees over-ran the country, entirely reduced the Fantees, and besieged the British settlement. A mission was now therefore sent to the king of Ashantee, to conciliate his good-will toward this country, to obtain, if possible, an extension of commerce, and to gain a knowledge of that kingdom, and the adjacent countries.

ASHANTEE, according to the elaborate account of Mr. Bowdich, employed on this mission, is situated at a distance from the coast, on the west of Dahomy, and nearly in the longitude of the central parts of England. Its extent is supposed to be great, though still imperfectly known to Europeans, and must, indeed, be so in a great measure to the inhabitants themselves. Where

no records are kept, and the communications are only received from those who levy the tribute, no great accuracy can be expected, either as it relates to extent of country or number of inhabitants. It spreads principally over a wide space westward and towards the interior. Ashantee Proper does not border on the coast which is occupied by the tributary countries. The surface of this country is variegated, but the cultivation is partial, and much of it is over-run with forests of brush-wood, and the luxuriance of a tropical vegetation. A river called the Volta is formed of two streams which intersect the Ashantee territory. South-east of Coomassie, the capital, a small lake is laid down in Mr. Bowdich's map. No means of ascertaining the population presented itself to the members of the mission, but by that of the military force. Of this they give the following, as the most moderate estimate received :

Coomassie district, extending to the northern frontier	60,000
Dwabini ditto	35,000
Morpon ditto	15,000
Soota ditto	15,000
Kakoofoo ditto	15,000
Beequa ditto	12,000
Adiabini ditto (between Coomassie and the lake)	12,000
Aphwagwiasee ditto	10,000
Daniasee ditto (southward of Coomassie)	8,000
Koontarasee ditto (on the lake)	8,000
Gomasie ditto	8,000
Amafas ditto	8,000
	206,000

The Ashantees being a nation of warriors, this statement may amount to nearly one-fifth of the whole population, which will, therefore, be about one million. The area of Ashantee Proper is estimated by the same writer at 14,000 square miles, which is consequently about seventy-one persons to each; a population rather greater than that of Scotland. The climate of Ashantee is colder than that of Cape Coast. During May and June, the first two months that the mission was at Coomassie, it rained about one-third of the time; in July and August, it rained nearly half, and violent tornadoes, ushered in by strong winds from the south-west, were frequent after sun-set. The heaviest rains fell from the latter end of September to the beginning of November, when they descended in more impetuous torrents than are usual on the coast. On the second of May Fahrenheit's thermometer rose to 91°, and the following day, at twelve o'clock, it was 89°. From the 7th to the 14th of June, it varied at Coomassie from 80° to 85°. It appears that the general temperature of Coomassie, during the hottest part of the day, is between 70° and 84°.

The agriculture and products are similar to those of other parts of south-west Africa. The soil is chiefly a light loam, and the only agricultural instrument is the hoe. Their plantations have much the appearance of hop-grounds, are well formed and regularly planted; a hut being

erected at each wicker-gate where a slave and his family generally reside. They grow two crops of corn a year; plant their yams about Christmas, and dig them up in September. They also cultivate rice, sugar-canes, a mucilaginous vegetable, called encruma, resembling asparagus, pepper, vegetable butter, oranges, papaws, pine-apples, and bananas. Fine cotton also grows spontaneously in Ashantee. The cattle seen by the embassy were as large as those in England. The horses are small, and the Ashantees bad horsemen. The Moors sometimes ride oxen with rings through their noses. The sheep are covered with hair. Among the wild animals are lions, panthers, elephants, hyænas, goats, deer, and antelopes; besides abundance of the monkey species: of these, the simia diana, is much admired for the beauty of its skin. The alligator, rhinoceros, and hippopotamus, are also met with; among the birds vultures are numerous, as well as pigeons, crows, and parrots. Various singing birds were likewise seen. Ashantee either is not a mineral country, or the inhabitants cannot avail themselves of its treasures, as the gold and other metals are imported. Iron-stone, however, is found in several places, and particularly in the neighbourhood of Coomassie, the metropolis, which is built upon the side of a large rocky hill, and is insulated by a marsh northward. This marsh contracts into a narrow stream on the southern and eastern sides, and supplies the town with water. Around the town is a beautiful forest. Coomassie is an oblong of nearly four miles in circuit, not including the suburbs of Assafoo, or Bantama (the black town), half a mile distant, and formerly connected with the streets. Four of the principal of these streets are half a mile long, and from fifty to a hundred yards wide. Mr. Bowdich observed them building one, and a line was stretched on each side to make it regular. The streets are all named, and a superior captain has charge of each. That where the mission resided was called Apheremsoo, great-gun, or cannon-street, because the guns taken when Dankara was conquered, were placed on a mound at the top of it. The Ashantees asserted that the entire population of Coomassie exceeded 100,000; and Mr. B. says, that on festivals, when the people were collected, he compared the crowds to those he had seen in the secondary cities of England. The higher classes support their numerous followers, and the lower their large families, in plantations within two or three miles of the capital. Mr. B. thinks the average resident population of Coomassie, exclusive of those of the surrounding crooms, does not exceed 15,000. There are two markets held daily, from about eight o'clock in the morning till sunset, where the articles exhibited for sale, are beef and mutton, hogs, deer, and monkey's flesh; fowls, with the vegetable products of the country; salt and dried fish from the coast, large snails smoke-dried, and stuck in rows on small sticks in the form of herring-bone; eggs for fetish, palm-wine, rum, pipes, beads, looking-glasses, sandals, silk and cotton cloth, gunpowder, small pillows, white and blue cotton thread, calabashes, &c. Provincial capitals, and other large towns of the

interior, were spoken of to the gentlemen of the mission, but were little known, it appeared, at the capital.

The king's love of justice is esteemed by his courtiers as his chief virtue. They have no ideas of extending their influence by civil policy. The cefoceers, or military captains, accordingly form the lowest grade of the constitution, over whom are placed the heads of but four families, which form a sort of aristocracy, and, with the king, complete the three estates of this kingdom. In exercising his judicial authority, or in laying the basis of a new law or measure, the king always retires in private to consult these four chief dignitaries; but every law is announced publicly to them as well as to the assembly of captains, as the arbitrary pleasure of the king. On state emergencies only, are the latter assembled distinctly, or to give publicity to some new law. The Ashantees are fully capable of vindicating this constitution by argument, according to the testimony of our officers who visited the court of Coomassie; indeed, no system of government would seem better suited to their habits and propensities. The captains are made responsible, in a great degree, for the issue of their own advice with respect to war or peace; we only wish we could add, that in their mode of conducting hostilities, they were as humane as they are energetic and skillful.

In this respect, they are still barbarous in the highest degree. They rarely give quarter in a general action, and a distinct body of recruits follows the army to despatch with knives those who are wounded with a musket, and return with the personal spoil of the enemy. They even make a practice of cutting out the hearts of some of the slain, which they mix up with consecrated herbs, and after much ceremony and incantation, compel those who have never before killed an enemy, to eat part of the horrible portion. Of the heart of a celebrated enemy, the king and his dignitaries are said to partake; and their most warlike generals are distinguished by names descriptive of their peculiar modes of despatching or torturing their enemies. Thus, Apokon, the king, is called Aboâwessa, because he has been in the habit of cutting off their arms; Appia, Shemboo, because he beats their heads in pieces with a stone; and Amanqua, Abiniowa, because he cuts off their legs. Sir Charles McCarthy, it is feared, was despatched by these barbarians in this cruel manner.

The last power subdued, or the revolters recently quelled, are always compelled by the Ashantees to form the van of their army; the youngest captain marches first, and all the authorities in gradation of rank and seniority up to the king. The superior discipline and courage of their soldiery were in a moment perceptible, when they appeared in conflict with the people of the coast before Annamaboe; but the following are said to be the only maxims to which this is to be attributed: They never pursue an enemy at or near sunset; the general is always in the rear, the secondary captains and the soldiers on, while the chiefs of divisions, surrounded by a few select followers, urge them forward with heavy swords, and cut down every

man who retreats, until the conflict is desperate. In close fight, the principal effort of the Ashantee is to fire, and then spring upon the throat of his enemy. The most popular song of the capital, has a sort of chorus to this effect: 'If I fight I die, if I run away I die, better I go on and die.'

At the Yam Custom, an annual festival, and at the death of their great men, hundreds of human victims are said to be regularly sacrificed, and the skulls and other bones of their enemies are exhibited in their armoury, and as the ornaments of their state apartments. At all their great festivals and funerals, indeed, the slaughter of human beings is horribly frequent. Some of the former occur once in three weeks, when 100 are sometimes immolated. It should be observed, however, that these are often convicts. The king celebrated the death of his mother by the sacrifice of 3000 victims; and the funeral rites of a great caboceer were repeated at intervals for three months, during which 2400 persons were butchered.

According to the religious belief of the Ashantees, there are two distinct orders of gods; one of which, the higher order, takes care of the whites, the other of the blacks; they are believers in the immortality of the soul, and both their princes and nobility are supposed to enjoy the presence of the higher order of their deities after death. Here they regale themselves in epicurean indulgence, and have cooks and butlers after the fashion of their country. Persons of this description are, therefore, buried with their great men, whose reception in another world is supposed to be greatly regulated by the number of attendants with which they appear. The Ashantees have also two sets of priests; one class being devoted to the services of their temples and to preserving a communication with their deities, and the other class a sort of conjurors, and detectors of small theft. Every housekeeper also has his domestic gods and charms, bought of these cunning men. Polygamy is universally allowed, and the king claims the royal number of 3333 wives, which is regularly kept up; the ladies living in round enclosures, 'like pheasants in a park.'

A peculiar feature in the law of succession obtains in this country, and is binding from the royal family downwards. The brothers' children are always set aside in favor of sisters' children, on the ground that if the sons' wives are faithless, the blood of a family is lost in the offspring; but should the daughters deceive their husbands the father's blood is still preserved; thus, the sisters of the king are allowed to intrigue or marry with any personable man. The king is heir to all the gold of any subject, and contributes to the funeral rites to assert his claim; the successor paying the debts of the deceased. Slaves, if ill treated, may transfer themselves from one master to another. They are a great article of traffic here, and the domestic drudges, of course, of the country. No topic appeared so inexplicable to the king as that of the British motives for abolishing the slave-trade. The slaves of an ally or tributary are scrupulously restored; those of an indifferent or enemy's

country may become free subjects of the state. An appeal lies for the subjects of any tributary power to the laws, and ultimately to the king of Ashantee.

Cowardice, treason, the murder of an equal, and some cases of adultery, are punishable with death, as are false accusations of treason. A great man killing his equal, is generally afterwards allowed to kill himself as a punishment; but the death of an inferior is compensated by a fine, paid to the family, of the value of seven slaves. Serious thefts are punished with a compensation inflicted on the family of the accused, who alone are suffered to punish him; but this they may do even capitally, if he be incorrigible. Trifling thefts are visited on the offender by exposing him at various parts of the town, and proclaiming his crime before him. But all vexatious suits and accusations are discouraged and punished. Polygamy is allowed to all ranks, but the wife's property is distinct from that of her husband, and the king is the heir of it. None but a captain can put his wife to death for infidelity, and even then he is expected to accept a liberal offer of gold for her redemption. To intrigue with the king's wives is death. If the family of a woman, on her complaint of ill-treatment, choose to tender to a man his marriage-fee, he must accept it; and the wife returns to her father's house, but can no more marry. 'The most entertaining delassement of our conversation,' says Mr. Bowdich, 'with the chiefs, was to introduce the liberty of English females; whom we represented, not only to possess the advantage of engaging the sole affection of a husband, but the more enviable privilege of choosing that husband for herself. The effect was truly comic; the women sidled up to wipe the dust from our shoes with their clothes, at the end of every sentence brushed off an insect, or picked a burr from our trowsers; the husbands expressing their dislike by a laugh, would put their hands before our mouths, declaring that they did not want to hear that palaver any more, abruptly changed the subject to war, and ordered the women to the harem.'

The foreign trade of Ashantee is regulated by the government, so far as to interdict commerce with any unfriendly power. It is in every other respect left free, though not much encouraged. The slaves of the capital are generally a part of the annual tribute of the neighbouring powers; but many are kidnapped throughout the country. They fetch but a trifle; but it is the most lucrative branch of their commerce with the coast; and the continuance of it under other flags, particularly the Spanish, while the British are prohibited from engaging in it, is represented by the intelligent writer, to whom we have been already so much indebted, as the most stubborn impe-

diment to the negotiations which he had to conduct at Ashantee. 'It not only injures the British commerce here,' says Mr. B. 'almost to annihilation; but, slavery being the natural trade of the natives, because it is the most indolent and the most lucrative, the opposition, which is insinuated and believed to proceed from the English alone, conveys a disagreeable impression of us to the interior, as inauspicious to our intercourse and progress, as the even partial continuance of such a trade is to legitimate commerce and civilisation. One thousand slaves left Ashantee, for two Spanish schooners, or Americans under that flag, to our knowledge, during our residence there; doubtless the whole number was much greater. Since our return it must have been very considerable, for the slave trade was never more brisk than it is at this moment, under the cloak of the Spanish flag; and great risk has been incurred, in consequence, of offending our new friend and formidable neighbour, the king of Ashantee, from the firm resistance of his strong entreaties to the governor-in-chief to allow the return of a powerful mulatto slave-trader to Cape Coast Town, whence he had been expelled under the present governor, as the most daring promoter of that commerce.' How urgently does this press upon government, by all legitimate means, to urge the universal abolition of this accursed traffic! It is but 'crippled,' as this writer well remarks, at present, 'at the expense of our own interests and views in the interior; and, which is worse, of the happiness and improvement of the natives.'

Gold was seen everywhere in great abundance by the British emissaries; and the court of Coomassie, in silks, stuffs, cloths, and cottons, of every hue, was most imposing. Some of the captains wore ornaments of solid gold on their wrists, so large as to tire the hand, which rested on the head of a young slave. The tops of immense umbrellas were decorated with golden heads of pelicans, panthers, baboons, &c. as large as life.

Guns and gunpowder are never allowed to be exported from Ashantee; and the people in general have no idea of buying any thing but for the purpose of consumption, except a small number of articles of which they can make a profitable barter for tobacco, cloth, and silk, in the Inta and Dagwumba markets. Their situation bids fair, however, for their becoming the complete brokers between the interior and the European nations.

We subjoin a table of the most material articles of commerce between our settlement at Cape Coast Castle and the Coomassie market, and the profit they will yield, according to Mr. Bowdich, at the latter:

CAPE COAST.					COOMASSIE.				
Articles.				Quantity.				Quantity.	Profit per cent.
	£.	s.	.		£.	s.	d.		
1 Cushions	—	—	—	—	1	0	0	each.	100
2 Dagwumba white cotton	—	—	—	—	0	5	0	square yard.	100
3 Flints	0	5	0	100	0	0	$\frac{1}{2}$	each.	600
4 Glasgow Dane	1	10	0	per piece.	0	5	0	per handkerchief.	75

18 Tobacco, Portuguese	6	0	0	Roll.	10	0	0	roll.	75
19 — Inta	—	—	—	—	0	2	6	lb.	150

* The span is about nine inches long; the fathom eight spans.

Gold dust is the currency of Ashantee, worth about £1 English an ounce. That of the neighbouring kingdoms of Inta, Dagwumba, Gaman, and Kong, is reckoned in cowries, of which five strings, or 200, make a tokoo; eight tokoos an ackie; and sixteen ackies an ounce.

Mr. Bowdich recommends that a British settlement should be attempted up the Volta, which is navigable within four days' journey of Sallagha, the capital of Inta, east of which, and on the banks of Laka river, connected with the Volta, is the kingdom of Dagwumba. These tributary nations to Ashantee are far more commercial in their policy than that state; and, as far as they have become known to us, more civilised. They give exorbitant prices to the Ashantees for rum, iron, &c. Silks, Manchester cloths, and cottons, would find a market in the same direction.

In their architecture the Ashantees have claims to surprising neatness, and even elegance. Although the walls are of mud, every house in Coomassie has its regular gable ends, from which three poles are projected, i. e. from end to end, forming the point and bottom of the roof on each side; in which a frame of bamboo work supports an interwoven thatch of palm leaves, tied with the runners of trees. Within, the bamboo work is painted black and polished, so as to form a sort of chequered and tasty ceiling. The pillars that assist to support the roof, and form the open front of the superior houses, are squared pieces of timber, covered with plastering, and often or-

namented with fluting, quarter-foil, and the lozenge and gable ornaments of the Normans. The steps and raised floors of these houses are clay and stone, covered with a layer of red earth which has the appearance of ochre. Arcades and piazzas abound everywhere in the capital. The doors are generally an entire piece of the cotton wood; the windows open wood work, carved in fantastic shapes, and painted red; the frames being frequently cased in gold as thick as cartridge paper. Mr. Bowdich was agreeably surprised to find every house have its cloaca in some retired and arched corner, besides the common ones about the town for the lower orders. The holes, he says, are dug to a surprising depth, and boiling water is poured down them every day. The rubbish and offal of the houses is burnt every morning in the back of the street. In their persons, and in all their domestic economy, the Ashantees are also patterns of cleanliness.

They manufacture cloths of exquisite fineness and brilliancy of color, sometimes unravelling the finest silks, to weave them into them. They paint on white cloths; and dye with considerable skill, particularly leather; in pottery, blacksmith's work, tanning and dressing leather, they also excel. They will buy British cottons for the sake of a favorite stripe (generally the red), and cutting away the other parts, weave it up into their own cloths, which alone are worn as articles of dress.

ASHBORN, or ASHBOURN, a town in Derbyshire, on the borders of Staffordshire, between the rivers Dove and Compton, thirteen miles from Derby, and 139 N. N. W. from London

It has a stone bridge over the Dove; an ancient church with a fine spire; and a free school, founded by citizens of London, natives of the place. Its trade in malt and cheese is consider-

able. A weekly market is held here, and several annual fairs. Population 2112.

ASHBURNHAM, a post town of the United States, in Worcester county, Massachusetts, on the west side of the river Sowhegan, forty-five miles north-west of Boston.

ASHBURTON, a town in Devonshire, seated on the river Dart, ten miles from Totness, nineteen south-west of Exeter, and 192 west by south of London. It carries on a considerable trade, in wool, yarn, and serges; has markets on Tuesday and Saturday, and fairs on the first Thursday of March and June, and on the 10th August and 11th November. It sends one member to parliament, and is one of the four stannary towns. It is seated among the hills, which abound in tin and copper; and has a very handsome church, with a chapel, which is used as a school. Population above 4000.

ASHBY DE LA ZOUCH, a market town of Leicestershire, so called from the Zouches, its ancient lords, 13 miles south of Derby, 15 from Leicester, and 115 from London. It has seven annual fairs. It long had a castle, which was in the possession of the family de la Zouch. It afterwards fell into the hands of Edward IV. who granted it to Sir Edward Hastings, with the title of a baron, and license to make a castle of the manor-house, to which he adjoined a very high tower. James I. and his whole court were once entertained here by the Earl of Huntingdon. It was demolished in 1648. Malting, and the manufacture of hats and cotton, flourish here. Population upwards of 3000. In the neighbourhood is a mineral water called Griffydham.

ASHDOWN, a town of Essex, anciently called Assandun, or the hill of asses, famous for the defeat of Edmund Ironside, by Canute the Dane.

ASHER; אֲשֵׁר, Heb. i. e. blessedness; one of Jacob's sons by Zilpah, and the progenitor of the tribe so called.

ASHEREF, or **ASHRAFF**, a town of Persia, in the Mazanderan province, half a mile from a large bay, the best harbour on the south side of the Caspian. Shah Abbas built a superb palace here, surrounded by fine gardens, remarkable for the number of their orange trees. This palace is now falling to ruins. Distant fifteen miles from Fehrad, and sixteen from Sari.

ASHES, among the ancient Persians, were used as an instrument of punishment for some great criminals. The criminal was thrown head-long from a tower fifty cubits high, which was filled with ashes to a particular height, 2 Mac. xiii. 5, 6. The motion which the criminal used to disengage himself from this place, plunged him still deeper into it, and this agitation was farther increased by a wheel which stirred the ashes continually about him, till at last he was stifled.

ASHES, in chemistry, are the earthy particles of combustible substances after they have been burnt. If the ashes are produced from vegetable bodies, they contain a considerable quantity of fixed salt, blended with the terrene particles: and from these the fixed alkaline salts called pot-ash, pearl-ash, &c. are extracted. See **POſASH**, &c. The ashes of all vegetables are vitrifiable, and found to contain iron. They are also an

excellent manure for cold and wet grounds. See **HUSBANDRY**.

ASHES were anciently used in several religious ceremonies. St. Jerome relates that the Jews in his time rolled themselves in ashes, as a sign of mourning. To repent in sackcloth and ashes is a frequent expression in Scripture for mourning and being afflicted for our sins. There was a sort of lye and lustral water made with the ashes of an heifer sacrificed upon the great day of expiation; the ashes whereof were distributed to the people, and this water was used in purifications as often as any touched a dead body, or was present at funerals, Num. xix. 17.

ASH-FIRE, among chemists, a fire wherein the vessel to be heated is covered with ashes or sand.

ASHI, a prince of Norway, said to have been slain by Fingal, the father of Ossian, at a place of Invernesshire, ever since named Drumashi, or Ashi's Hill.

ASHIMA, an idol of the Samaritans, 2 Kings xvii. 30, said to have been formed like a lion or a goat, and to have represented the sun.

ASHING-KEY, a low island on the Spanish main, on the Mosquito shore.

ASHIPOO, a river of North America, in South Carolina, which runs into the Atlantic. Long. 80° 30' W., lat. 32° 25' N. Also a town of the same name situated on the banks of this river.

ASHLAR, in masonry, free-stones as they come out of the quarry, of different lengths, generally applied to slabs of stone, from six to nine inches in thickness, used for facing brick buildings, worked in imitation of regular courses of solid masonry.

ASHLER, or **ASHLERING**, quartering of timber about three feet high, placed perpendicularly from the floor of the attic story, to the roof to obviate the useless angle formed by the junction of the roof and the floor.

ASHLEY, a river of South Carolina, rising in Cypress swamp, and emptying itself into the Cooper just below Charleston. Its breadth opposite Charleston is about 2100 yards, and its stream narrows but little for several miles. On the western bank of this river the first efficient settlement of the state was made at a place now called Old Town, or Old Charleston, in 1671. Also a river of West Florida, which runs into the Gulf of Mexico.

ASHMOLE (Elias), a celebrated antiquary and herald, founder of the Ashmolean Museum at Oxford, was born at Litchfield, in Staffordshire, 1617. He first practised in the law: in the civil war he had a captain's commission, and was also comptroller of the ordnance under Charles I. In 1649 he settled at London; where his house was frequented by most of the learned men of the age, and a depository of many literary treasures. In 1650 he published a treatise written by Dr. Arthur Dee, relating to the philosopher's stone; with another tract on the same subject by an unknown author. About the same time he was busied in preparing for the press a complete collection of the works of such English chemists, or alchemists rather, as had till then remained in manuscript. This undertaking cost him great labor and expense; but at length the work appeared towards the close of

the year 1652, under the title of *Theatrum Chymicum Britannicum*. He proposed at first to have carried it on to several volumes; but afterwards dropped this design, and applied himself to the study of antiquity and records. He was at great pains to trace the Roman road, which in Antoninus's Itinerary is called *Bennevanna*, from Weedon to Litchfield. In 1658 he began to collect materials for his celebrated history of the Order of the Garter. In September following he made a journey to Oxford, where he commenced his full and particular description of the coins presented to the public library by archbishop Laud. Upon the restoration, Mr. Ashmole was introduced to king Charles II. who bestowed on him the place of Windsor Herald. Soon after he appointed him to give a description of his medals, which were accordingly delivered into his possession, and king Henry VIIIth's closet was assigned for his use. Mr. Ashmole was afterwards admitted a fellow of the Royal Society; and the king appointed him secretary of Surinam, in the West Indies. On the 19th July 1669, the University of Oxford, in consideration of the many favors they had received from Mr. Ashmole, created him M. D. by diploma. In May 1672 he presented his Institution, Laws, and Ceremonies of the Order of the Garter, to the king, who, as a mark of his approbation granted him £400 out of the custom on paper. On the 26th January, 1679, a fire broke out in the Middle Temple, in the next chamber to Mr. Ashmole's, by which he lost a noble library, with a collection of 9000 coins, ancient and modern, and a vast repository of seals, charters, and other antiquities and curiosities; but his manuscripts, and his most valuable gold medals, were luckily at his house at Lambeth. In 1683, the University of Oxford having finished a magnificent repository near the theatre, Mr. Ashmole sent thither his collection of rarities; which benefaction was augmented by the addition of his manuscripts and library at his death, which happened at Lambeth, May 18, 1692, in the 76th year of his age. Besides the works above mentioned, Mr. Ashmole left several which were published since his death, and some which still remain in manuscript.

ASHMOT, the principal part of the Isle Madame, dependent on the island of Cape Breton,

ASHO'RE. On shore. Ang-Sax. *sciran*, to shear, cut, divide, separate. See **SHORE**.

Swear then how thou escap'st.

Swam *ashore* man like a duck! *Shakespeare*.

For now the flowing tide,

Had brought the body nearer to the side;

At more she looks, the more her fears increase,

At nearer sight; and she's herself the less:

Now dry'n *ashore*, and at her feet it lies,

She knew too much in knowing whom she sees.

Her husband's corpse. *Dryden's Fables*.

[He] Then with his dire associates through the deep,
For spoil and slaughter guides the savage prow,
Him dogs will rend *ashore*.

Alberci's Leonidas, book xii. p. 77.

Thus while their cordage stretch'd *ashore* may guide,

Our brave companions thro' the swelling tide;

This floating lumber shall sustain them o'er

The rocky shelves, in safety to the shore.

Falconer's Shipwreck

ASHTAROTH, ASHTORETH; אַשְׁתָּרִיָּה, Heb. i. e. flocks, or riches; or **ASTARTE**, the chief goddess of the Sidonians and Phœnicians, called also the Queen of Heaven, and reckoned the same with the Juno of the Greeks and Romans. Cicero, however, calls her the Venus of Syria, wherein he is certainly justified by her mode of worship; which, like that of the Grecian Venus, abounded in all manner of debauchery. The Israelites, in all their relapses to idolatry, showed a great fondness for her worship. Solomon himself in his dotage sacrificed to her. She was represented in various habits, encircled with rays, &c. We find a place named after her in the days of Abraham; Gen. xiv. 5.

ASITON (Charles), an antiquarian and one of the most learned critics of his age, was elected master of Jesus College, Cambridge, July 5th, 1701, and installed prebend of Ely, on the 14th. His skill in ecclesiastical antiquities was equalled by few.

ASHTON (Dr. Thomas), a native of Eton, studied at Cambridge, in 1733, was successively rector of Aldingham, Starminster, and St. Botolph, Bishopsgate. In 1759 he took his degree of D. D.; and in May 1762 was elected preacher at Lincoln's Inn, which he resigned in 1764. He died in 1775, aged fifty-nine.

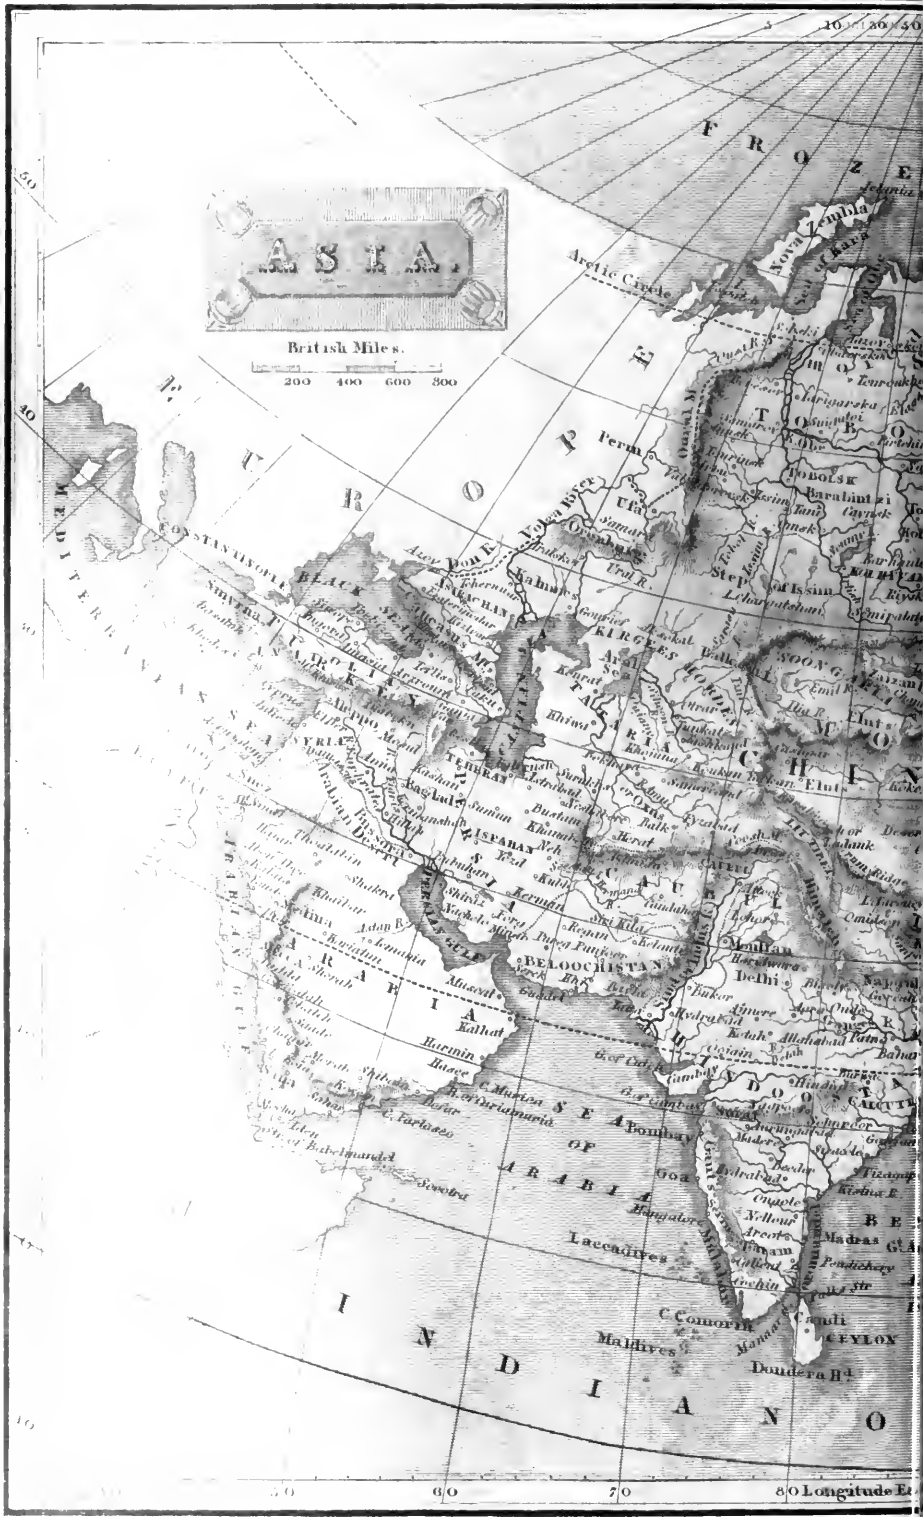

ASHTON-UNDER-LYNE, a town and parish in the hundred of Salford, county palatine of Lancaster, England, 186 miles N. W. of London. The town stands on the northern bank of the river Tame, consists of several narrow streets, many large factories, a parish church, chapel of ease, and other buildings for the happiness and convenience of a population of about 15,000 souls. The cotton and woollen manufactures are carried on here extensively, and the collieries in the vicinity augment and employ the population. Traffic is also much promoted by the transit of the Rochdale canal by this place. The benefice is a rectory in the diocese of Chester, the patronage belonging to the earl of Stamford, who is also lord of the manor. This place is one of the new boroughs enfranchised by the reform bill, and returns one member to parliament. The mayor is the returning officer. At the village of Fairfield in this parish is a Moravian settlement, in which the males are employed in spinning and weaving.

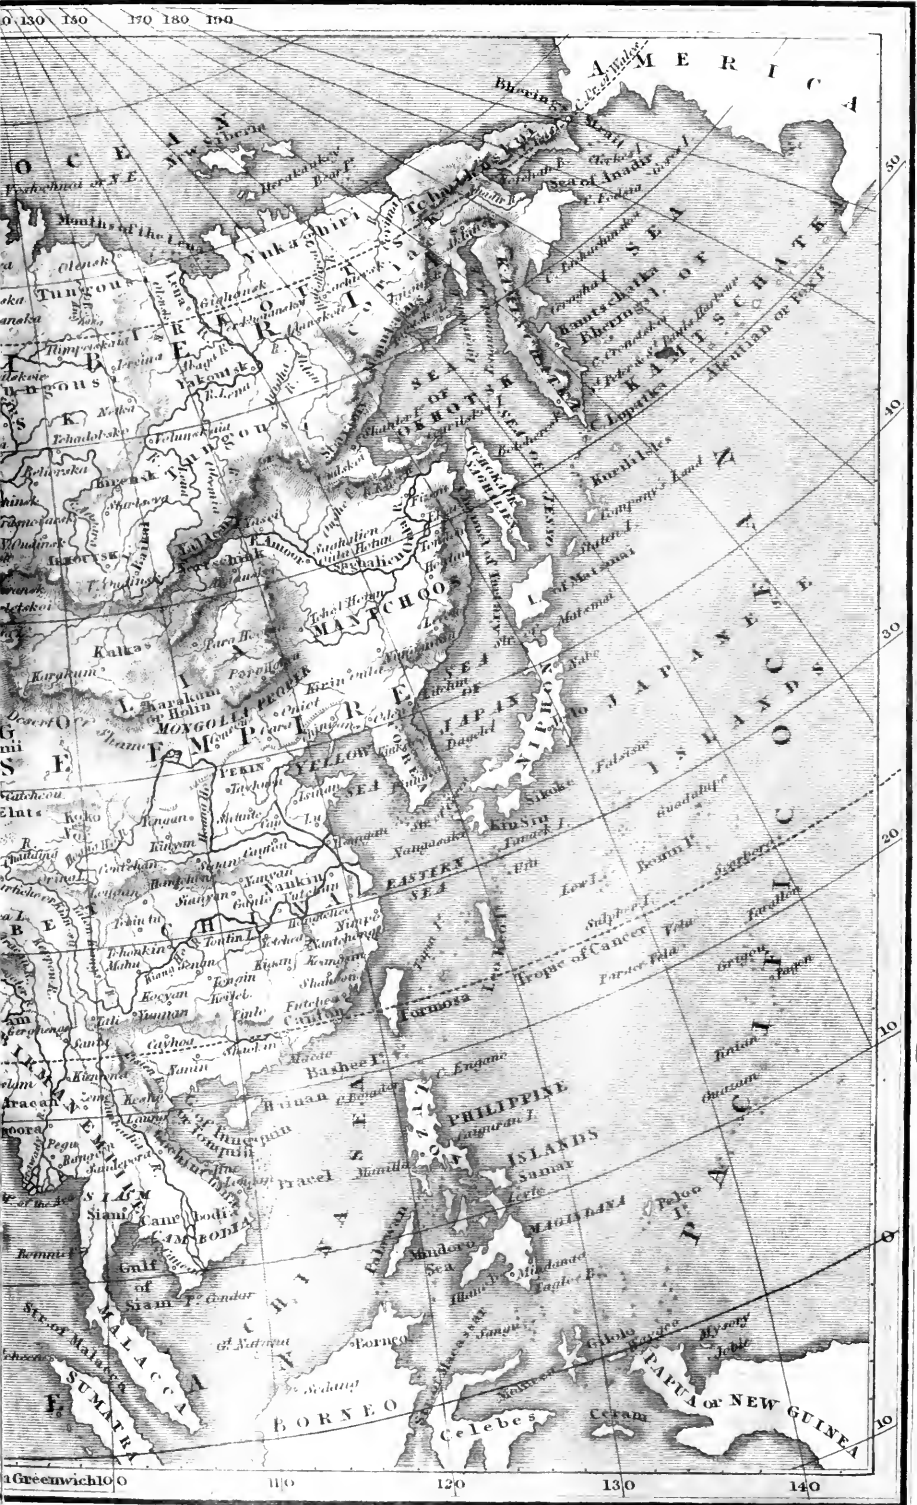

ASHUR, אַשּׁוּר, Heb. i. e. blessed, the son of Shem, and progenitor of the Assyrians.

ASH-WEDNESDAY, the first day of Lent, so called from the ancient custom of sprinkling ashes on the head.

ASHWELL (George), rector of Hanwell, son of Robert Ashwell, of Harrow, was born at London in 1612, and admitted in Wadham College, Oxford, in 1627, where he took his degrees of A. M. and B. D., and was elected a fellow and tutor. He died at Hanwell, in 1693. He wrote, 1. A discourse, asserting the received authors and authority of the Apostle's Creed. Oxon. 1653. 2. A double Appendix, touching the Athanasian and Nicene Creeds. 3. On the Gesture at receiving the Sacrament, 1663. 4. A Treatise concerning Socinus, and the Socinian Heresy. 5. A Dissertation on the Church of Rome. Ox. 1618.

Engraved on Steel by J. Shury

A S I A.

ASIA, in geography, one of the great divisions of the earth, lies to the east and south-east of Europe. North and south it stretches from about 2° to 77° of north latitude. East and west it extends from about 26° east, to 170° west longitude. Its northern capes penetrate the ice of the polar regions, while its southern promontories approach nearly to the centre of the torrid zone. Its greatest length in this direction is taken at something more than 5200 English miles from east to west. The extent of this continent from the western shores of Natolia, to East Cape, in Siberia, has been accurately calculated at 8000 miles.

BOUNDARIES.—It is bounded on the north and south by the Arctic and Indian Oceans; on the east by the Pacific Ocean and the Chinese Sea; and on the west by the Arabian gulf, the Isthmus of Suez, the Mediterranean, the Archipelago, the straits of Gallipoli, the sea of Marmora, the Bosphorus, and the Black Sea, whence to the Arctic Ocean the boundary which separates Asia from the east of Europe is not distinctly ascertained. It is, however, supposed to be constituted by the rivers Don and the Karposca, one of its tributary streams rising near Sarepta, the course of which is to be continued by an imaginary line between the 40^{th} and 50^{th} of east longitude.

ISLANDS.—The islands belonging to Asia are the Prince's Islands near Constantinople, Mitylene, Scio, Samos, Cos, Rhodes, Cyprus, &c. in the Archipelago. Bahrein on the Arabian side of the Persian gulf noted for its pearl fishery. The Laccadive, Maldivé islands, and Ceylon in the Indian Ocean, contiguous to the peninsula of Hindostan. East of the Bay of Bengal lies the Indian Archipelago, consisting of numerous different groups of islands including the Andaman and Nicobar islands, the Sunda isles, Sumatra, Java, and Borneo; the Moluccas or Spice islands, Papua or New Guinea, Solomon's isles, Queen Charlotte's isles, and the New Hebrides; which bending in a circular direction to the south-east lead us to the two islands of New Zealand. New Holland, to the south of New Guinea, is the largest island in the world, and contains an area larger than all Europe. East of the New Hebrides lie the South Sea islands. North of New Guinea are the New Carolinas and the Marianne or Ladrone islands. West of them are the Manillas or Philippine islands, and the Mindanas or Magindanas north of the Moluccas. Immediately above Luzon is the Isle of Formosa. East of Formosa in the Chinese sea lie the Lieù-Kieù, or Lutchù islands. Still farther northward we have Nison and other islands which together form the kingdom of Japan; from which proceed the Kuriles, consisting of numerous groups of little islands, extending in a chain from the isles of Japan to Cape Lopatka, the southern extremity of Kamtschatka. West of these on the coast of Tartary lie Saghalien and other islands. A little distant from Kamtschatka are the Aleutian or Fox islands,

proceeding in a curved line to the opposite extremity of America. Nova Zembla is also by some geographers considered as an Asiatic island, and lies to the north-west of Siberia. The islands of Ramisseram and Manar are curiously connected by a singular ridge of rocks called Adam's Bridge. It is nevertheless proper to observe that the best of later geographers, concurring in the opinion of the learned president des Brosses, have separated a vast number of the islands, formerly considered as Asiatic islands, from that continent, and arranged them with a number of other countries and islands to the south of Asia, and in the Pacific Ocean, under the two divisions of Australasia and Polynesia. The grounds of the new arrangement are explained with sufficient clearness by Mr. Pinkerton in his introductory observations on the Asiatic islands.

SEAS and WATERS.—Besides the great oceans which wash three sides of this celebrated quarter of the globe, there are numerous gulfs, bays, and inland seas which have greatly contributed to its fertility and civilisation. The Red sea or Arabian gulf, called the Weedy sea by the Hebrews, forms the grand natural division between Asia and Africa. Its length calculated from the straits of Babelmandel to the isthmus of Suez, is about 1470 English miles, and its medial breadth 140 miles. It terminates at the upper extremity, in two great branches, of which the western, by several miles the longer, is celebrated for the passage of the Israelites in the month Nisan, B. C. 1497, supposed to have taken place in about $29^{\circ} 40'$ north latitude. The eastern branch extends a little above the parallel of Mount Sinai. The Arabian sea is an appellation applied to the vast bay, included between Arabia and Hindostan, terminating in the Persian gulf, to which it is united by a strait twenty-four miles wide. This gulf stretches to the north-west between Arabia and Persia, containing several islands, and terminates under the same meridian as the Caspian. The deep and extensive Bay of Bengal, spreading from the eastern coast of Hindostan to the opposite shores of the Burman Empire, is separated from the last mentioned sea by the great promontory of the Deccan. This bay forms a magnificent inlet to the central part of southern Asia. At its entrance, which is in the eighth degree of latitude, it exceeds 1300 miles in width, and is 1000 miles from that parallel to its northern extremity, beyond the mouth of the Ganges. The gulf of Siam, on the opposite side of the peninsula of Malacca, separates the territorial projection from the broad rectangular peninsula included in the southern part of the Burman empire. The gulf of Tonquin lies on the south of China; the Yellow sea between China Proper and the gulf of Corea. The straits of Corea eastward lead to the sea of Japan; which stretches through about fifteen degrees of latitude, and divides the Japanese islands from the shores of the continent. This sea decreasing to the north terminates in a channel

leading to the sea of Okotsk which forms a spacious inlet to the south-eastern shores of Siberia, dividing Chinese Tartary from the peninsula of Kamtschatka. From the top of this sea projects a large forked gulf through nearly three degrees of latitude between two chains of magnificent mountains; one on the peninsula and the other on the continent. This gulf, and a bay on the opposite shore, render the conformation of the north-eastern part of Asia, peninsular. The sea of Anadir a few degrees south of Behring's strait forms another inlet to the north-eastern extremity of this continent. A few deep inlets are found on the shores of the Arctic Ocean. Passing from the White sea through the strait of Waygat, between Nova Zembla and the continent, we enter the gulf of Cara, which is divided from the deep gulf of Oby, by a long peninsula. This forms a large opening reaching nearly to the sixty-fifth parallel. The river Yenisei eastward forms itself into a wide estuary before it falls into the sea. The Bay of Tainourskaia, which from its situation is sometimes called the North Gulf, is placed about the seventy-fifth degree of latitude near the northern extremity of the Old World. Numerous other inlets are found along the coast from this point to Behring's strait. The Levant and the Archipelago lie on the western side of Asia, north of the Isthmus of Suez. The Euxine, or Black sea, forms the northern boundary of Anatolia, and is considered for the most part as a detached sea, being united to the Mediterranean only by a small strait, the Bosphorus of the ancients, so narrow as to be called the Canal of Constantinople.

The sea of Marmora, or Propontis, is considered by some an inland sea, and is connected with the Egean Sea, or Mediterranean Archipelago, by a similar strait called the Dardanelles, or ancient Hellespont. This sea, as well as the Black Sea and Mediterranean, is supposed to have been anciently detached. The Caspian, celebrated for its fisheries, forms the separating boundary, which divides Russia from Persia and independent Tartary. It is of elliptical figure; the major axis extending nearly 700 miles from north to south, and occupying a breadth of nearly 200 geographical miles. It appears to have extended much farther north than it does at present; especially as the deserts in that direction are saline, and sandy, presenting the same kind of shells and marine productions as are found in the waters of the Caspian. Pliny and Strabo supposed this sea to be a gulf of the northern ocean; but it must always have been restricted by the western branch of the Uralian mountains, which passes to the north of Orenburg, reaching to the Volga. Its former union with the Lake Aral is highly probable from the marine deposits found in the intervening steppes, and from the Salt Lake still remaining between them; the midway eminence having been occasioned perhaps by the alluvion from the great rivers which flow into the latter. The Caspian is remarkable for its having no visible outlet for the discharge of its waters, notwithstanding the large rivers that flow into it, and also from the evidences of a former superior elevation being visible in the flanks of the moun-

tains forming its western coasts. M. Pallas imagined he recognised its ancient shores on the steppe, considerably higher than its present level; and has given some particulars on the subject. M. M. Engelhardt and Parrot, naturalists from Prussia, who visited this sea in 1815, place the former shores of the Caspian about 350 feet higher than its present surface; where they found gulfs and bays clearly defined. Its islands are mostly uninhabited; its bed is uneven, abounding with shoals, between some of which a line of 450 fathoms has been unsuccessfully employed to reach the bottom. Its waters are less salt than those of the ocean; but have a peculiar bitter taste. It has no tides; but is subject to violent storms. The striking peculiarity of this sea is the difference between its level and that of the Baltic and the Black Sea. From barometrical observations made at Astracan, and at St. Petersburg, during a period of nine years, the Caspian appeared to be 306 feet below that of the Baltic: and from other barometrical observations, made between the mouth of the Kuban and that of the Terek, the surface of the Black Sea was found to be 105 metres, or 344.5 feet above the Caspian.

Lake Aral is about 200 miles in length, and seventy in breadth, and about an hundred miles distant from the eastern shores of the Caspian; which, in some respects, it may be said to resemble: it extends in the same direction, and receives the waters of several rivers, but discharges none. The principal rivers that run into it are the Gihon, or Jihon; the Oxus, of antiquity, which enters the southern extremity; the ancient Jaxartes, which reaches it from the east; as also the Aujany, or Kizil Daria. The southern extremity of this lake is sprinkled with numerous islands; and its supplies of water flowing from the south and the east, while those of the Caspian flow from the north and west, evince that they occupy part of the same natural basin. Baikal, another of the great lakes, or inland seas, of Asia, is situated near the southern borders of Siberia, on the northern side of the great chain of mountains which divides that country from Mongolia. This lake, like the former, stretches in the same direction as the Caspian: is 350 miles in length, and nearly forty in breadth. Its waters are fresh and pellucid, presenting however the general appearance of a slight green tinge, and are usually frozen from the beginning of December to the end of April. The depth of this lake varies from twenty to ninety fathoms; but so clear are the waters, that the bottom becomes distinctly visible to the depth of fifty feet. It is subject to violent storms, and is often agitated without any visible cause; whence it has received from the Russians the superstitious name of *Svetoie Marè*, *Holy Sea*. This lake, although it receives the waters of several copious rivers, has no visible outlet except the lower Angara, the discharge from which is considerably inferior to the accessions which it receives. It is almost surrounded by mountains, in which the existence of subterraneous fire is evident, from frequent shocks of earthquakes; and the surrounding shores are distinguished by some remarkable phenomena.

It has been imagined by many geographers that the northern regions of Asia communicate with the continent of America. This however is a topic on which we have not sufficient data to ground an opinion. Captain Cook certainly traced the separation of these continents, partially: The best information yet obtained on this particular is, that Behring's Strait divides them to about forty miles in breadth, having East Cape on the Asiatic side, and Prince of Wales Cape on the American. The depth of water is about thirty fathoms. Pursuing this strait northward, the Asiatic shore tends rapidly to the west, while the American proceeds nearly due north; till, at the distance of four or five degrees, the two continents are joined by one solid and impenetrable mass of ice.

MOUNTAINS.—The mountains of Asia have always been thought remarkable; and, arrayed in all the horrors of perpetual winter, seem to frown in awful silence over the profusion of the vale.

A celebrated writer (M. Walckenaer, in his *Cosmologie*, p. 105,) observes, 'that the chain of mountains in which the culminating points of the highest level are found, always follows the direction of the greatest dimensions of the continent; and the inferior chains or heights, where we find the culminating points of the second or third-rate levels, also follow the direction of the greatest dilatations of the land, terminating that continent.' In Asia we have an illustration of these observations. The greatest dimensions of the continent are from east to west: and the country from the seventieth to the 100th degree of east longitude, and from the thirtieth to the fiftieth of south latitude, presents nearly a level area, from the different sides of which all the largest rivers flow into the sea. The culminating points of this extensive level, there is reason to believe, are the most elevated spots on the surface of the earth. The included area has been termed the table-land of Asia; although, since the revival of science, it has been inaccessible to European travellers, and therefore little known. The western part of it is, however, mountainous; and the eastern is a vast desert; the Shamo of the Chinese, and the Kobi of the Tartars, exhibiting an extent of several thousand miles not watered by a single stream.

The Altaian mountains are the northern boundaries of this area; the Himálaya, on the south, divide it from Hindostan. On the east is that lofty range in which originates the great rivers of China; and the west is bordered by the mountains which contain the sources of the Indus and Jaxartes. The inferior chains, diverging as radii from this centre, are Múz-dágh or Múz-zárt, 'snowy mountains,' on the north. The Tibetan mountains on the east, the Vindhya hills and Ghats on the south, and the Alburg or Alborg on the west. The different ranges that traverse the territories of Persia, and unite its north-west provinces to Caucasus on the north, to Taurus and Libanus on the west and south, are connected with the Alburgian chain. Libanus is also connected by the hilly country on the west of Jordan with the mountains of Arabia. The greater number of these inferior chains run from east to west, in the same direction as the central range.

The extensive Altai, or Khattai chain, stretches across the continent, under different names, for more than 5000 miles, terminating, to the east, in Tchutskoi Ness and cape Lopatka. Of the highest points of this celebrated chain south of Russia, we have no accurate information; but the inferior ranges reach far above the point of perpetual congelation, and are supposed to be equal to the Alps. The Himálaya chain of mountains south of the great central level, rears its loftiest summits 26,000 feet above the level of the sea; and, according to some of our best geographers, upwards of 6000 feet above the celebrated Chimborazo of America, which towers over the entire Cordillera of the Andes. This southern chain is supposed to be of superior elevation to the northern. Mount Kailás, the Olympus of the Hindus, is supposed to exceed even the D'hólá-giri in Nipál, which has been proved by admeasurement to reach 26,400 feet above the level of the sea. Mount Caucasus, the next in point of altitude, is a vast range extending between the Euxine and Caspian seas. Mount Ararat rises south-west of the Caucasus; Libanus, Amanus, and Taurus, are all connected with this great chain; and the latter mount diverging with various branches, occupies almost the whole area from the Euphrates to the sea of Marmora. The Uralian mountains, running from south to north, nearly as far as Nova Zembla, and called by the Tartars the girdle of the earth, are much colder, in consequence of a higher latitude; but are inferior to the above in point of elevation.

Many volcanoes are in a constant state of activity throughout Asia; and many which were volcanic in former times, are now extinct, although smoke still issues, and hot streams are frequently discharged from crevices in their sides. The insular regions of Asia are likewise mountainous, and Adam's Peak, in Ceylon, has been a remarkable subject of tradition and fable. Volcanoes are also found in most of the Asiatic islands; Gúnong-ápi is one of the most active now known; and that near Brambanan, in Java, a violent eruption is recorded in 1586. Ternate, the chief of the Moluccas, is nothing more than a volcanic cone, occasionally emitting flames from its summit; and on its sides are large pits of melting sulphur. The isles of France and Bourbon are entirely of volcanic origin; and the crater of the latter, while in a state of eruption, was visited by M. Bory de St. Vincent, who describes, with great interest, the phenomena observed on that occasion.

RIVERS.—From the mountains of Asia numerous rivers descend, which serve greatly to refresh the surrounding country. The river Lena rises east of Siberia, near the lake Baikal, and flowing first north-east, then north, enters the Frozen Ocean, opposite the Borkhaya isles, after a course of 1900 miles. The river Enisei, rising in the Altaian mountains, flows into the same sea after a course of at least 1400 miles. The Oby, perhaps the widest river in the Russian empire, rises about 51° north latitude, and 87° east longitude from the Altúrnor of the Kalmaks, and Ozero Teletzkoi of the Russians; and after a course of not less than 2000 miles, falls into the Obskaya Juba, or sea of Oby, within the arctic circle. The

river Irtysh takes its rise in 46° north latitude, and 92° east longitude, in the northern barrier of the central plateau; and after rolling its rapid stream as far as the 62d degree of latitude, and gathering numerous tributary waters in its course, falls into the river Obc, north of Samarou. The Amour, or Saghalia, which rises in the Kalcas country, is formed by the junction of the two rivers, Kberton and Argun; and after traversing Chinese Tartary, and receiving several large rivers in its course, disembogues itself in the sea of Okhotsk, near the northern extremity of the channel of Tartary, completing a course of 1800 miles. The rivers of China chiefly rise in the eastern declivity of the Table Land. The Mékäng, or Kambója, and the Irawadi, or Ava River, after descending from the plateau into the lower country by long and winding courses, flows in a direct line to the Indian Ocean. The three most celebrated rivers that spring from this region are the Indus, Ganges, and Burrampooter. The Ganges river is held sacred by the inhabitants, and is the only one of the three of whose source we have any satisfactory information; although Mooreroft tells us he found that of the Indus in 31° 3' north latitude, and 80° 35' east longitude. The two others rise in Thibet; the Burrampooter waters the eastern parts of Bengal; and the course of the Indus, to the south, has been known ever since the time of Alexander. The Oxus and the Jaxartes are two large streams, well known to the ancients, which rise from the western declivity of the central range; the former emanating from the glaciers of Pushti-khur, is supposed anciently to have taken a north-westerly course; at present it proceeds almost due north, and falls into the lake Aral. The latter rises in the Belúrdágh or Icy mountains, west of Afghánistáun, and enters the eastern side of the same lake. The Tigris and Euphrates flow to the south, and the Araxes to the east, watering a considerable extent of country. The Jordan and Orontes fertilize and beautify the vales of Syria and Palestine. Anatolia, though it has neither broad nor rapid rivers, is refreshed by the division of innumerable smaller streams, which throw an enchanting appearance over the surface of the landscape. The Halys, or Kizil Irmá, arising from mount Taurus, after a course of 350 miles, falls into the Black Sea. But the Howang-hò, or Yellow River, which waters the northern provinces of China, is perhaps the deepest and most rapid river of Asia. This river rises on the eastern declivity of the plateau, and rolls its vast stream with unabated rapidity, to nearly 2000 miles. The Yang-tse-kiang, or son of the sea, is another noble stream of China.

CLIMATE.—The climate of Asia is exceedingly various, owing to the different degrees of elevation. In the south-east the heat is excessive, and in the northern parts the cold is almost insupportable. In Anatolia the central parts are colder than the provinces of France, although the latter are ten degrees farther north. The cause of this is explained by Mr. Brown, who calculates that the city of Erz-rum is 7000 feet above the level of the sea. This extraordinary altitude of level, together with the great body of snow on the neighbouring mountains, accounts for the

extremes of cold in Persia and Tartary; Arabia is considerably tempered, though within the tropics. China being mountainous has an agreeable climate; while in India and the Burman empire, are sensibly experienced the full effects of a torrid zone.

VEGETABLES.—The stupendous mountains, immense plains, immeasurable forests, noble rivers, and wide spreading marshes of this quarter of the earth, together with the variety of the soils, and an extreme difference of climate, from the intense cold of Siberia, where mercury freezes, to the almost insupportable heat of the sandy deserts: from the eternal frost that reigns around the pole, to the sterility of the arid waste, including diversified intermediate regions, always adorned with the blossoms of spring, enriched with the fullness of summer, or laden with the productions of autumn, produce an unparalleled variety of vegetation, from the almost imperceptible moss that creeps along the Arctic shores to the hundred-stemmed banian that spreads its beautiful luxuriance beneath a tropical clime. Some parts of Asia are very sterile, and the inhabitants look for support to the surrounding sea, in which fishes and mollusca abound. Vegetable productions however, generally speaking, are numerous, and differ according to the climate under equal circumstances of soil and irrigation. The central and western parts produce all sorts of grain which are common in Europe, and culinary vegetables in the highest perfection. The tropical and southern regions afford gums, spices, medicinal roots, and extracts unknown in colder climates. Several genera of plants are peculiar to New Holland and the adjacent islands. The tea-tree is found chiefly in the central regions; and the bread fruit and bamboo, which are natives of Asia, are useful in every part of domestic economy.

MINERALS.—This division of the globe contains the precious metals in great abundance: gold is washed down the rivers of Asia Minor. Arabia still supplies it in its utmost purity; and in Assam, Celebes, and Borneo, the gold is said to be native. Mount Sipylus has been celebrated for the production of silver, and the mines of Tokat supply both silver and copper. Great quantities of tin are found in the island of Banca; lead and iron in various parts of the continent; precious stones are found in great variety throughout the whole of Asia; fine diamonds in Golconda; rubies in Ceylon, topazes in Siberia; and the most beautiful pearls in the straits of Manaar and the Bahrein islands; the corundum and other valuable stones are peculiar to these countries. Singular remains of antiquity are also dug out of the earth; huge tusks of a species of animal now unknown, and even the entire animal itself, is found in the islands of the Frozen Ocean.

ANIMALS.—Asia contains a great variety of land and marine animals, from the minute insect that flutters in the solar beam, to the stupendous elephant, the ferocious tiger and the majestic lion. The most valuable are indigenous to this quarter of the globe. The horse is found on the northern confines of Persia in his native state,

but exhibits none of the symmetry, powers, or proportions, to which he arrives through a course of domestic training. The camel is found here in his most perfect growth, and performs journeys which to the horse would be fatal. The elephant is trained to all sorts of service. The sea-otter, so valuable for his fur, and the whale are common, and supply a considerable source of wealth to the inhabitants.

'The population of Asia,' it has been observed, 'by no means equals those expectations which its history would naturally inspire,' owing to the ravages of war, and the influence of despotic governments, which always impose an effectual check upon the increase of population. Nevertheless, where the governments are mild and beneficial, as in British India, the reverse is the fact. China in particular, owing to a long freedom from foreign and domestic war, is said to exhibit the amazing population of five hundred millions; and even this, according to some geographers, is below the real amount.

Asia, however, being the scene of human origination, is still peopled by numerous indigenous tribes, and presents an ample field for the study of man, in all the stages of his progress from barbarism to civilisation. The variety observed in the appearance of the natives is probably the effect of difference of climate, aliment, and religion. The Samoied tribes, New Hollanders, and inhabitants of Andaman, are of diminutive size. The people of Jessó and the Kurile islands, have uncommonly large beards, and an unnatural profusion of hair all over their bodies. The Tartars and Chinese are known by the peculiar figure of their faces; the latter particularly by their oblique contracted eyes. There is, however, reason to believe they were anciently derived from one common origin, and bore a great resemblance to each other.

HISTORY.—Noah is said to have settled in Asia, immediately after the deluge, near the borders of the Euphrates, and to have peopled the whole continent. The posterity of Shem occupying the central regions; Japhet the northern; and Ham the southern. Javan and his descendants, Ashkenaz, Dodanim, Tarshish, Elisha, Togermah, and Riphath, are supposed to have been the ancient inhabitants of Asia Minor. The Canaanites and Amalekites were the people of Syria and Arabia Petræa. Modern writers have referred the present natives of Asia to those different stocks the Hebrews, Indians, and Tartars, the propriety of which will appear from their make, features, and languages. There are, however, some large tribes, as the Malays and aboriginal negroes, which cannot be referred to either of these classes, as also the mountaineers of Caucasus, and the inhabitants of northern Siberia. Mr. Pinkerton observes, that the population of Asia is allowed by all authors to be wholly primitive and original; with the exception of the Tshuktsis, whom the Russian historians suppose to have passed from the opposite coast of America, the colonies that have migrated from Russia to the northern parts as far as the sea of Kamtschatka, the well-known European settlements, and a few others. Asia certainly presents an amazing original population. We add the following table of

the nations and languages in Asia, as calculated to give the reader a tolerably accurate idea of this interesting subject of enquiry.

Table of the Nations and Languages in Asia.

1. Assyrians.—Assyrians, Arabians, Egyptians.—Chaldee, Hebrew, &c.
2. Scythians.—Persians, Scythians intra et extra Imaum, &c. Armenians.—(The Parsi and Zend are cognate with the Gothic, Greek, Latin, according to Sir William Jones. *Asiatic Dissert.* vol. i. p. 206. The Pehlavi is Assyrian or Chaldaic. *Id.* 187, 188. 206.)
3. Sarmats.—Medes and Parthians.—Georgians and Circassians.
4. Seres and Indi.—Hindoos, northern et southern, &c.
5. Sinc.—Chinese and Japanese.—These have a Tartaric form and face; they are probably highly-civilised Tartars, Mongoles, or Mandshurs.

Barbaric Nations from north to south, and according to the degrees of barbarism.

6. Samoyedes, Ostiaks, Yurals, &c.
7. Yakutes.—Yukagirs. (Expelled Tartars, according to Tooke and Lesseps.)
8. Koriaks.—Tshuktsis. (From the opposite coast of America. Tooke's Russia. The Yukagirs are a tribe of the Yakutes, around Yakutsk, and both are expelled Tartars. Tooke's View, ii. 80. Lesseps, ii. 312.)
9. Kamtskatdales.—Kurillans.—(These resemble the Japanese.)
10. Mandshures or Tunguses.—Lamutes.—(Ruling people in China.)
11. Mongoles.—Talmuks.—Soongares, Tungutes, Buræts, &c.
12. Tartars or Huns.—Turks, Khasares, Uzes, and Siberians.—Nogays, Bashkirs, Kirghisikazaki or Kirghise Kaizaks, Teleuts.

After the destruction of Attila's swarms, and the effects of unfortunate inroads, the Huns became subject to the Mongoles, who under Zingis, or Chingis khan, Timur, &c. consuted the supreme nation in Asia.

The great share of population which Europe has received from Asia will appear from the following brief statement.

Primitive Inhabitants.

1. Celts.—Irish, Welsh, Armorican.—Erse, Manks, Cornish.
2. Fins (chief god Yummala).—Finlanders, Esthoniens, Laplanders, Hungarians, Permiens or Biarmians, Livonians, Votiaks and Cheremisses, Vogules and Ostiaks.

Colonies from Asia.

3. Scythians or Goths (Odin).—Icelanders, Norwegians, Swedes, Danes, Germans, English.—Swiss, Frisic, Flemish, Dutch.
4. Sarmats or Slavons (Perune).—Poles, Russians, Kaizaks.—Heruli, Vendi, Lettes.

The inhabitants of France, Italy, and Spain, are also of Asiatic origin; and speak corrupted Roman, which, like the Greek, is a polished dialect of the Gothic, according to Sir William Jones, and other able antiquaries. The Heruli

Vendes, and Lettes, used mixed and imperfect dialects of the Sclavonic.

Besides these numerous original nations, the Malays and Asiatic islanders constitute another large and distinct class of mankind, with a peculiar speech, in the south of the extensive continent of Asia.

GOVERNMENTS.—The people of Asia in their civil state consist of families occupying the same territory, but acknowledging no chief or governor; of independent tribes associated under one common potentate as the Arabs and Tartars, and therefore called equestrian nations; or of kingdoms ranged under established monarchies, of which the chief are Independent Tartary, China, Thibet, with its subsidiary provinces, the Japanese empire, &c. The Asiatic governments are mostly despotic, and those established by Europeans are nearly of the same description. In some of the political institutions of Asia there is, however, the rude image of a popular administration; in others the influence of women is admitted; whilst in some few the prince is guided in all public measures by the advice of his nobles. Were the principal governments in Asia to be arranged according to their natural and political importance, they would probably succeed each other in the following order: China in the first place, and after this successively Persia, Turkey, and Russia; the precedence of the numerous other states can hardly be ascertained.

RELIGION.—The most common religion of Asia is idolatry. The doctrines of Mahomet prevail to a great extent; but their influence is upon the decline, owing in a great measure to the popularity of the Wahabees. Christianity is now generally rejected in Asia, and in many countries even where it was formerly tolerated, as in China and Japan. The sacrifice of animals, and even of human victims, is very frequent; and a spirit of the most degrading superstition seems to reign throughout the vast regions of this division of the globe. Penance is carried beyond even the bounds of probability. Imposing upon himself perpetual silence, gazing on the sun till his eyes become fixed in their sockets, lacerating his body with sharp weapons, and other practices still more shocking to humanity are, through vast regions, considered among the most acceptable services which a man can offer to the deity. Polygamy is generally practised, and sometimes even a plurality of husbands are allowed to a single woman: females of rank also, betrothed at an early age, cohabit not with their husbands but with other men without reproach. Infanticide is common; and burning the living wife with the body of her dead husband, though now rendered a voluntary act on the part of the woman, has by no means subsided. Many of the tribes are complete cannibals, and others are little better.

CHARACTER OF INHABITANTS.—The inhabitants of Asia, violent in their dispositions, are generally ferocious, vindictive, and cruel. The tender ties of nature are little felt. Children are openly sold by their parents without even the apology of necessity. Wives are sacrificed by their husbands even on the bare suspicion of infidelity; and in the most civilised state after an

unfortunate contest for the crown, the unsuccessful prince, if not executed, invariably has his eyes put out, though the rival should be his own brother.

The ancient geography of Asia cannot be contemplated without feelings of excitement, which the deep gloom of her present degraded and idolatrous condition are unable to suppress; feelings unknown in the contemplation of any other portion of the globe. Asia was the parent of nations, the cradle of civilisation and science—here occurred most of those remarkable transactions recorded in the scripture history—here arose successively the Babylonian, Assyrian, and Persian empires—and here the Christian religion was first planted for the salvation of man. Much of the celebrity of this quarter of the globe is undoubtedly owing to its climate, and the numerous gulfs, bays, and navigable rivers with which it abounds opening early facilities for commerce, &c.; but still more perhaps is to be attributed to the native genius and sanguine temperament of its inhabitants.

The origin of the name of Asia has given rise to some curious speculations and disquisitions. The Greeks deduced it from Asia, the fabulous daughter of Oceanus and Thetis. Others have derived it from Asius, king of Lydia. Bochart traces it to the Hebrew or Phœnician word *Asi*, signifying middle, which is, however, unsupported by historical evidence. According to Homer, Herodotus and Euripides, it early designated a country of Lydia, where ancient geography mentions a tribe of Asiones and a city of Asia. The name, however, was gradually extended by the Greeks from a single province to the whole of Asia Minor, and afterwards to other regions as they were discovered successively; in the same manner as *Allemagne* is applied by the French to the whole of Germany; and as *Italia*, an ancient canton in Calabria, is now denominated the peninsula of Italy. Since, however, much perplexity has arisen among authors by the diverse acceptations of the term Asia, so as to render it extremely difficult for their readers to know what region was distinctly understood by that appellation; and since it is not easy to reconcile the apparent inconsistency between sacred and profane history, as to the provinces which it comprised, we present the following observations for the satisfaction of the reader:—The ancient geographers divided the vast continent that was known to the Greeks and Romans under the word Asia, first into Greater and Lesser Asia. The latter, also called Asia Minor, was thought to be a peninsula terminated by a line drawn from Sinope to the line of separation between highland and lowland Cilicia (*Aspera* and *Campestris*). It comprehended a great number of provinces; but that which included Phrygia, Mysia, Caria, and Lydia, was denominated Asia Proper, or Asia properly so called. Cicero, enumerating the regions contained in Asia Proper, makes no mention of *Æolis* or *Iolia*, though undoubtedly a district of it, as being comprehended partly in Lydia and partly in Mysia. Lydia, beside the inland country commonly known by that name, contained also *Ionia*, lying on the sea-side, between the rivers *Hermus* and

Mæander; and Æolis, extending from Hermus to the river Caicus, or to the promontory Lectum, the ancient boundary between Troas and the sea-coast of the Greater Mysia. Accordingly, Asia Proper comprehended Phrygia, Mysia, Lydia, Caria, Æolia, and Ionia. This tract was bounded, according to Ptolemy, on the north by Bithynia and Pontus, extending from Galatia to Propontis; on the east by Galatia, Pamphylia, and Lycia; on the south by part of Lycia and the Rhodian sea; on the west by the Hellespont, by the Ægean, Scarian, and Myrtoan seas, occupying the space between the thirty-fifth and forty-first degree of north latitude, and extending from 55° to 62° of longitude.

As Asia Proper is but a part of Asia Minor, so the Lydian Asia is only a part of Asia Proper. Asia, in this acceptation, comprehends Lydia, Æolia, and Ionia; and is that Asia whereof mention is made in the Acts and the Apocalypse. Aristotle tells us that Smyrna was at first possessed by the Lydians; and Scylax Coryandensis reckons it among the cities of Lydia, as also Ephesus, Sardis, Philadelphia, and Thyatira, are reckoned by Ptolemy among the cities of Lydia, as is Laodicea by Stephanus. Steph. de Urbid. That in ancient times Lydia was called Mæonia, and the Lydians, Mæonians, is manifest from Herodotus, Diodorus Siculus, Dionysius Afér, Strabo, Pliny, Stephanus, and others; and that Mæonia was called Asia is no less plain from Callinicus, who flourished before Archilochus, from Demetrius Scepsius, contemporary with Crates, and Aristarchus the grammarian, from Euripides, Suidas the great etymologist, &c.; besides which it is expressly affirmed by the ancient scholiast of Apollonius Rhodius, that Lydia was formerly called Asia, and hence Lydia has been said to have a better claim to the name of Asia than any other part of that continent. Ulterior (or Greater) Asia comprehended the remaining part of that continent. Its great divisions were Iberia, Colchis, and Albania, between the Euxine and Caspian seas; Mingrelia, Georgia, and Daghistan Armenia, which retains its ancient name. Media and Persia included in modern Persia. Bactriana and Margiana; the Merri, Balkh, and Bokhàra of the Turks and Tartars; Syria, Mesopotamia and Assyria; the Bilâdu'sh ishâm, Diyar bekr, and Abjonirah of the moderns. Hyrcania, Persia, and Susiana, the Irâk and Fârs of the present day. Judea, Babylonia, and Chaldea; the southern part of Syria and Pachalic of Bagdad. India the country between the Indus and Ganges, and Syria the remoter regions to the north-east.

ANCIENT GEOGRAPHY.—The earliest accounts of this vast portion of the globe are those contained in the Scripture, which are, however, extremely imperfect. Moses has enumerated the different parts of the earth with which the Hebrews were familiar; but, in consequence of the names by which he designates the places differing from other authors, great obscurity hangs over the whole of his geography, except that which relates to the land of Canaan itself, and the states immediately contiguous. He appears to have been well acquainted with Asia Minor, Armenia, Media, Persia, and Arabia. The Gog

and Magog of Scripture seem to have been the inhabitants of Caucasus. Riphath seems to refer to the Riphæan mountains; and Rosh refers to the ancient Rossi, from whom were descended the Russians of the present day. The more northerly parts of Asia were evidently unknown to the Greeks. Herodotus considered the Phasis in Colchis as the line of separation between Europe and Asia, whilst others believed the Don, or Tanais, as the proper limit. The mountains north of India were the utmost boundary of their knowledge with respect to that part of Asia. The Ganges and the Indian Ocean they considered the eastern and southern limits; and the Red Sea, with the isthmus between it and the Mediterranean, brought them back to the western or nearest side. Many geographers included Egypt in Asia, making the Catabathus, or western side of the valley of the Nile, the separation between Asia and Africa; whilst others considered the Nile itself as the line of separation. Strabo and Pliny supposed the northern end of the Caspian sea communicated with the ocean.

PROGRESSIVE GEOGRAPHY.—At the time when Asia was first mentioned in history it probably contained more powerful empires than it does at present, the Chinese excepted. Alexander the Great carried his arms beyond the Indus. The Sinæ, or eastern Indians, were known to Ptolemy in the second century, and also Taprobane or Ceylon, with Jabadia, the Javia dwipa of the Indians, and the Java of our maps. Alfred, king of England, deputed a mission to the shrine of St. Thomas on the coast of Babelmandel; and the crusades of Syria and Palestine, in the eleventh and twelfth centuries, led to an intimate acquaintance with that part of Asia. Shortly after the passion for crusades had subsided, a spirit of commercial enterprise was excited, and merchants, from several parts of Europe, penetrated into the interior. The monks, animated with a desire to convert the heretics, departed in great numbers for Asia; a mission deputed from the pope to the court of the Moguls, and another from Louis of France to the same princes contributed on their return, by the publication of their travels, to enlarge the ideas of Europeans with respect to that part of the world. Marco Polo, a Venetian merchant, with his companions, spent twenty-six years in travelling either as merchants, or as agents of the Great Khan of the Tartars, during which period they for the first time disclosed the great desert of Cobi, and made great additions to our knowledge of oriental geography, particularly in the north of Asia. Such indeed was the ignorance of the age in which he lived, that his descriptions of the magnificence and wealth of the Asiatics were regarded by his contemporaries as the effusions of romance. Subsequent information has nevertheless raised him to distinguished credit, and his work is now considered one of the most curious monuments we possess of the state of Europe and Asia in the middle ages. In the fifteenth century improvements in navigation, and the spirit of commercial enterprise, facilitated the progress of discovery. A passage was discovered to India round the Cape of Good Hope, and the

English, Dutch, Spanish, and Portuguese settled several establishments on the Asiatic coast, from which they undertook still more distant expeditions into the interior, and opened an intercourse with China, Japan, and Hindostan. The British government sent out repeated expeditions under the conduct of Cook, Byron, and others, to make discoveries in the Southern Ocean; and the empress Catharine about the same time directed scientific travellers to explore some of the central parts of her Asiatic dominions. Geography by these means received many splendid additions, and our knowledge of different and distant parts of the globe illustrated many important and interesting points in the physical and natural history of southern Asia. Van Diemen's Land and New Holland were explored by captain Flinders. The same voyager also observed that there is no river deeply penetrating into the latter island; and that the gulf of Carpentaria is a basin of vast extent studded with islands. The expulsion of the Dutch from their insular settlements has also led to an intimate acquaintance with those territories, all knowledge of which they endeavoured to conceal. Travellers from British India have greatly increased our information with respect to the neighbouring regions. A mission to the court of Persia has thrown a light on the geography and policy of that distinguished empire, and shown how defective our information was with regard to Oriental nations. A field of discovery, however, yet remains to complete the geography of this part of the world. The origin, course, and progressive increase of some of its greatest rivers are unknown; scarce any of its internal seas, except the Caspian, have been the subjects of actual survey; and its mountains, perhaps the most stupendous masses on the globe, present a wholly unexplored field of enquiry. Siberia is but little known; and even of the coasts no perfect survey has ever been taken. The whole extent of country from the Caspian to the sea of Okhotsk, including a superficial area of many thousands of miles, is occupied by nations and people whose names are scarcely known. Little more than the borders of Arabia is known to Europeans. The interior regions of Tartary and the northern part of China require much illustration. The same remark may be applied to India and the interior of Asia generally. With regard to the probable population of this continent so defective is our knowledge that differences of between one and two hundred millions exist in regard to that of China alone. Our knowledge of the islands is almost equally imperfect. Not a tenth part of New Holland has been attempted, and that only in a single line, although every journey unfolds novelties and wonders in nature which seem to distinguish this extensive island from every other region in the world. Borneo, Sumatra, Celebes, and Papua greatly demand the attention of travellers. The north-eastern angle of territorial Asia has been repeatedly visited by navigators and travellers since the civilization of Russia by the genius of Peter the Great; but the geography and natural history of that region have been hitherto described in a manner which is exceedingly imperfect. On the whole we are

looking for superior lights. The morning which dawned so many centuries ago has hitherto advanced but slowly; and we hail the approach of a brighter period, which is not very remote, when the sun of discovery shall burst the clouds in which he has been enveloped, and irradiate the geography of this interesting section of the globe.

The propagation of Mahomedanism, and the exterminating wars by which it was attended, effected a complete revolution by the states of this continent. The Greek empire sunk in the arms of the victorious Moslems. The caliphs for a time prevailed to a considerable degree over their Constantinopolitan predecessors, and were in their turn humbled by the Tatarian Jengerè and Témür. The latter were finally absorbed in the overwhelming power of the Turks who now, having no formidable enemy to oppose, overran the west of Asia, and in the middle of the fifteenth century extinguished the Eastern Empire, and laid the foundations of those great divisions of this continent which subsist at the present day.

With respect to the modern divisions of Asia, we observe that the Russian empire extends from the Uralian mountains to the sea of Kamtschatka, and from the Arctic Ocean to the parallel of fifty degrees north latitude. It is inhabited by Tartars, Mongols, Mantchirs, &c., under the general name of Siberia. The Asiatic part of the Ottoman Empire, consisting of Anatolia, Syria, and Diyar-Bekr, the ancient Mesopotamia, lies between the Black Sea and the Mediterranean; the canal of Constantinople and the Tigris; Arabia lies to the south of the latter country; and Persia lies east of the Tigris, as far as the Indus, between the Caspian Sea and the Persian Gulf. East of the Caspian, as far as east longitude 100 degrees, between Russia and Persia, are the independent Tartars. From the above meridian, to the Sea of Japan, lies eastern or Chinese Tartary, inhabited by the Mantchirs who subdued China in the middle of the seventeenth century, and whose original country forms at present the northern part of that empire. Thibet is on the north side of the Himàlaya mountains, the Alps of Hindostan. South and east of China lies the peninsula of India, beyond the Ganges. West of the Burman empire is India on this side the Ganges, comprehending Kashmir, Hindostan, and the Deccan. The islands are under various governments, and have been made the seat of various commercial establishments by the different powers of Europe, of which an account will be given under their names separately.

ASIA MINOR is the western portion of Asia, having the Black Sea on the north, the Euphrates on the east, and the seas Mediterranean and Marmora, with the Hellespont and Bosphorus, on the west. It is of an irregularly oblong figure, 1000 miles from east to west, and 400 or 500 from north to south, variously indented by bays and inlets, and having a few peninsulas and promontories. Its streams and rivers are numerous but not large; the interior abounding with saline lakes, crystal fountains, and hot-springs, whose waters have been cele-

brated for their medicinal qualities. The climate is fine, and its valleys warm, washed in some places by mountain torrents, shaded by the mountains, and tempered by cool and refreshing breezes from the sea. Long ranges of hills, from which branches diverge in all directions, isolated rocks and mountains crowned with trees and verdure, delightfully change the prospect; while the luxuriance of the soil and abundance of grain, fruits, and every species of vegetation, render subsistence comfortable and happy. Earthquakes are, however, frequent, overwhelming entire cities and their inhabitants; and the plague sweeps away its thousands. The whole country is subject to the Turkish government, and inhabited chiefly by Mahomedans and Christians. It is divided into several large provinces, of which Natolia and Caramania are the most important. It contains

the cities of Angora, Bursa, Smyrna, and Tocat besides the ruins of many others which have been highly celebrated in history. The southern shore of Caramania is overspread with remains of Grecian antiquities; and Natolia abounds with ancient curiosities and columns, having been the theatre of important events from the earliest history. The several islands in the Archipelago, belonging to this country, are also highly classical and important.

This part of Asia is the most interesting region of the earth, the parent of education, arts, and arms—the cradle of mythology, poetry, and eloquence—the favorite abode of the muses—the soil in which lay the ancient roots of genius, which have since struck round the world, beautified the moral wastes, and still luxuriantly expand their blossoms in almost every clime of the civilised globe.

ASIAGO, one of the seven Venetian communes in Upper Italy, in the midst of mountains, in the north of the circle of Vicenza, and now belonging to Austria. The inhabitants are descendants of the ancient Germans, and lead a purely pastoral life. They enjoyed great privileges under the Venetian government, and have more than once defended the passes of their country against the inroads of a foreign foe. The large town of Asiago is the seat of the court of justice for all the communes; has a castle, and 11,000 inhabitants. It is twenty miles north of Vicenza.

ASIDE. On side. See **SIDE**.

And he took him *asidis* frō the people and puttede hise fingris into hise ceris and he spette and touchide hise tonge. *Wyclif. Mark ch. vii.*

FRAN. Sir, he may live.

I saw him beat the surges under him,
And ride upon their backs; he trod the water,
Whose enmity he flung *aside*, and breasted
The surge most swoln that met him; his bold head
'Boveth contentuous waves he kept, and oar'd
Himself with his good arms in lusty strokes
To the shore; that o'er his wave-worn basis bowed.

Shakspeare's Tempest.

Thus (she pursu'd) I discipline a son,
Whose uncheck'd fury to revenge would run;
He chumps the bit, impatient of his loss,
And starts *aside*, and flounders at the cross.

Dryden's Hind and Panther.

It is the custom of the Mahometans, if they see any printed or written paper upon the ground, to take it up and lay it *aside* carefully, as not knowing but it may contain some piece of the Alcoran. *Addison.*

ASILUS, in entomology, the hornet-fly, a genus of insects belonging to the order of insecta diptera. It has two wings; and a horny, strait, two-valved, beak. There are seventeen species of this insect. Many of them would in a very painful manner, and are particularly troublesome to cattle in low meadows; others of them are quite harmless.

ASILUS, in ornithology, the name used by many for the luteola, or regulus non cristatus, an extremely small bird, common among willows.

ASINARI, an appellation given, by way of

reproach, to the ancient Christians, as well as Jews, from a mistaken opinion, among heathens, that they worshipped an ass.

ASINESIA, in medicine, an immovableness of the body, or in any part of it, as in apoplexy, palsy, &c.

ASINIUS LAPIS, a name given by some writers of the middle ages, to a stone, said to be found in those places frequented by the wild ass. See **BEZOAR**.

ASINUS PISCIS, in ichthyology, a name given by some to the agefinus, or common haddock, called also onos.

ASIO, in ornithology, a name given by Aldrovandus and others, to the otus, or lesser horn owl.

ASISIA, or **ASSISTA**, a town of Liburnia, now in ruins, but exhibiting many monuments of antiquity. It is the Asseria or Assesia of Pliny, and is now called Podgraje. See **ASSERIA**.

ASISIO, or **ASITIO**, a city of the Pope's territories in Italy, situated about sixteen miles east of Perugia, and eighty north of Rome. It is seated on a mountain, and is said to have been the birth-place of St. Francis.

ASK, } Ang.-Sax. *secan*, *ascecan*, to seek,
ASK'ER. } to ask; *asecan*, to seek, to ask. To seek, enquire, demand, require, petition, beg.

As it is a great point of art, when our matter requires it, to enlarge and veer out all sail; so to take it in and contract it, is no less praise, when the argument doth *ask* it.

Ben Jonson.

A lump of ore, in the bottom of a mine, will be stirred by two men's strength; which, if you bring it to the top of the earth, will *ask* six men to stir it.

Bacon.

When thou dost *ask* me blessing, I'll kneel down,
And *ask* of thee forgiveness. *Shakspeare.*

We have nothing else to *ask*; but that,
Which you deny already: yet will *ask*;
That, if we fail in our request, the blame
May hang upon your hardness. *Id.*

In long journeys, *ask* your master leave to give ale to the horses. *Swift.*

Let him pursue the promis'd Latian shore,

A short delay is all I *ask* him now;

A pause of grief, an interval of woe. *Dryden.*

Ask of the learn'd the way; the learn'd are blind;
This bids to serve, and that to shun mankind;
Some place the bliss in action, some in ease,
Those call it pleasure, and contentment these.

Pope. Essay on Man.

Upon my *asking* her who it was, she told me it
was a very grave elderly gentleman, but that she did
not know his name. *Addison.*

ASKANI, a town of Hindostan, in the northern
circar, Cicacole, thirty-six miles north by
west of Ganjam. It stands in N. lat. 19° 44',
E. long. 84° 55'.

ASKANCE', } Supposed to be from *as-*
ASKAUNCE', } *chined*, participle of the Dutch
ASKAUNT', } verb *schuinen*, to cut awry.
ASQUINT'. } From whence probably are
squint and asquint; sideways, oblique.

And wrote alway the names, as he stood,

Of file folk that gave hem any good,

Askance that he wolde for hem preyre.

Chaucer. The Sempnour's Tale.

Some say, he bid his angels turn *askance*

The poles of earth, twice ten degrees and more,

From the sun's axle: they with labour push'd
Oblique the centric globe. *Milton.*

Zelmaue, keeping a countenance *askance*, as she
understood him not, told him, it became her evil.

Sidney.

His wannish eyes upon them bent *askance*;

And when he saw their labours well succeed,

He wept for rage, and threaten'd dire mischance.

Fairfax.

While thus their worke went on with lucky speed,

And reared rammes their horned fronts aduance,

The ancient foe to man, and mortal seed,

His wannish eyes vpon them bent *askance*.

Fairfax's Tasso, book iv.

At this Achilles roll'd his furious eyes,

Fix'd on the king *askaunt*; and thus replies,

O, impudent—

Dryden.

Since the space, that lies on either side

The solar orb, is without limits wide;

Grant, that the sun had happened to prefer

A seat *askaunt*, but one diameter:

Lost to the light by that unhappy place,

This globe had lain a frozen loansome mass.

Blackmore.

Through his bright disk the stormy weapon flew,

Transpierc'd his twisted mail, and from his side

Drove all the skin, but to his nobler parts

Found entrance none by Pallas turn'd *askance*.

Couper's Iliad, book xi. p. 195.

—Panic-fix'd he stood,

His seven-fold shield behind his shoulder cast,

And hem'd by numbers with his eyes *askant*,

Watchful retreated.

Id. book xi.

ASKERON, a place five miles from Don-
caster, noted for a medicinal spring. It is a strong
sulphureous water, slightly impregnated with a
purging salt. It is recommended internally and
externally in strumous and other ulcers, scabs,
leprosy, and similar complaints. It is good in
chronic obstructions, in cases of worms, &c.

ASKEW'. Dan. *skiaert*, crooked; from *skiaer-*
er, to twist.

For, when ye mildly look with lovely hue,

Then is my soul with life and love inspir'd:

But, when ye lowre, or look on me *askew*,

Then do I die.

Spenser.

Then take it, Sir, as it was writ;

Nor look *askew*, at what it saith:

There's no petition in it

Prior.

This said, her spear she push'd against the ground,
And, mounting from it with an active bound,
Flew off to heaven: the hag with eyes *askew*
Look'd up, and mutter'd curses as she flew.

Addison. Ovid's Met. book ii.

ASKEW (Anne), an English lady, the
daughter of Sir William Askew, of Kelsay, in
Lincolnshire. She was born at her father's
seat about 1520; and received a liberal educa-
tion. Early in life she was married to a Mr.
Kyme, contrary to her own inclination; and,
being harshly treated by her husband, she went
to the court of Henry VIII. to sue for a separa-
tion. Here she attracted the particular notice
of such ladies as were attached to the reforma-
tion: on this account she was arrested; and,
acknowledging her religious principles, was sent
prisoner to Newgate. After having been put to
the rack with savage cruelty in the Tower, she
was burnt in Smithfield, along with her tutor,
and two other persons of the same faith, in 1546.
Her letters in Fox and Strype show her to have
been an accomplished and pious woman.

ASKEYTON, a market town of Limerick,
seated on the river Deel, 110 miles from Dub-
lin; noted for its castle, built by the earl of
Desmond, and for its beautiful abbey.

ASLA'KE. Ang.-Sax. *aslacian*, to abate;
to resolve, to unbend, to reduce to its compo-
nent parts, to slake, or slacken.

But this continual, cruel, civil war

No skill can stint, nor reason can *aslake*.

Spenser.

Whilst, seeking to *aslake* thy raging fire,

Thou in me kindest much more great desire. *Id.*

But suche as of ther golde ther only idoll make,
Noe treasure may the rauyn of their hungry hands
aslake. *Surrey.*

ASLAN, or **ASLANI**, in commerce, a name
given to the Dutch dollar in most parts of the
Levant. The word is also written corruptly,
asselani. It is originally Turkish, and signifies
a lion, which is the figure stamped on it. The
Arabs, taking the figure of a lion for a dog,
called it *abusket*. It is silver, but much al-
loyed, and is current for 115 or 120 aspers. See
ASPER.

ASLANT. On slant. See **SLANT**.

There is a willow grows *aslant* a brook,

That shews his hoar leaves in the glassy stream.

Shakspeare. Hamlet.

He fell; the shaft

Drove thro' his neck, *aslant*: he spurrs the ground;

And the soul issues through the weapon's wound.

Dryden.

Lo! now apparent all

Aslant the dew-bright earth and coloured air,

He looks in boundless majesty abroad,

And sheds the shining day that burnished plays

On rocks, and hills, and towers, and wandering
streams,

High gleaming from afar.

Thomson.

ASLEEP. On sleep. See **SLEEP**.

This false knight vpon delate

Hath taried till they were *asleepe*,

As he that woll time kepe

His deadly workes to fulfillle.

Gouer. Con. Am. book ii.

How many thousand of my poorest subjects

Are at this hour *asleep*! O gentle sleep,

Nature's soft nurse, how have I frighted thee!

Shakspeare

The diligence of trade, and noiseful gain,
 And luxury, more late asleep were laid:
 All was the night's; and, in her silent reign,
 No sound the rest of nature did invade. *Dryden.*
 For gorg'd with flesh, and drunk with human wine,
 While fast asleep the giant lay supine
 Snoring aloud, and belching from his maw
 His indigested foam and morsels raw:
 We pray, we cast the lots, and then surround
 The monstrous body, stretch'd along the ground.

Id. Virgil, Æneid iii.

There is no difference, between a person asleep,
 and in an apoplexy; but that the one can be awaked,
 and the other cannot. *Arbuthnot on Diet.*

ASLOPE'. On slope, or slip. See SLOPE.

For many times I have it seen,
 That many have begyled been,
 For trust that they have set in hope,
 Which fell them hereafter asleep.

Chaucer. Romaunt of the Rose, fol. 137. c. 1.

Set them not upright, but aslope, a reasonable
 depth under the ground. *Bacon.*

The curse aslope

Glanc'd on the ground; with labour I must earn
 My bread! what harm? Idleness had been worse;
 My labour will sustain me. *Milton.*

The knight did stoop,

And sate on further side aslope. *Hudibras.*

Where porters' hogsheads roll from carts aslope,
 Or brewers down steep cellars stretch the rope;
 Where counted billets are by carmen tost,
 Stay thy rash step, and walk without the post.

Gay. Trivia, book ii.

ASMODAI, the name given by the Jews
 to the prince of dæmons; and according to R.
 Elias, the same with Sammael.

ASMONEUS, or ASSAMONEUS, the father of
 Simon, and chief of the Asmoneans, a family that
 reigned over the Jews 126 years.

ASNA, or ESNA, a town in Upper Egypt,
 seated upon the Nile, believed by some authors
 to be the ancient Syena, though others say the
 ruins of it are still to be seen near Assuan. It
 is so near the cataracts of the Nile, that they
 may be heard from thence, and it contains sev-
 eral monuments of antiquity; among the rest an
 ancient Egyptian temple, painted throughout.
 The columns are full of hieroglyphic figures. A
 little way from hence are the ruins of an ancient
 nunnery, said to be built by St. Helena, and
 surrounded with tombs. Asna is the principal
 town in these parts, and the inhabitants are rich
 in corn and cattle.

ASNAPPER, an Assyrian prince, mentioned
 in Ezra iv. 10, who settled the original Samari-
 tans in the country of the ten tribes. It is un-
 certain, whether he was Salmaneser or Esar-
 haddon, or one of their generals.

ASOLA, a town of Upper Italy, in the terri-
 tory of Brescia, on the Chiese, with a popula-
 tion of 4000. It is twenty miles S.S.E. of Brescia.

ASOLO, a Venetian prefecture, in the March of
 Treviso, Italy; belonging to Austria. It con-
 sists of the town of Asolo, and thirty-six vil-
 lages, with 25,000 inhabitants. They cultivate
 grapes, corn, fruit, silk, oil, and garden ve-
 getables, trade in cattle, and manufacture silk and
 woollen stuffs. The town of Asolo is seated on
 some agreeable rising grounds, skirted on the
 north and west by the Musone.

ASOPH, or AZOPH. See AZOPH.

ASOPUS, a town of Laconia, on the Sinus

Laconius, with a port in a peninsula, between
 Boæ to the east, and the mouth of the Eurotas to
 the west. The citadel only remains standing.

ASOPUS, in ancient geography, the name o
 several rivers, viz. 1. In Bœotia, which, running
 from mount Cithæron, and watering the territory
 of Thebes, separates it from the territory of Pla-
 tæa, and falls with an east course into the Eurip-
 us, at Tanagra. On this river, Adrastus, king
 of Sicyon, built a temple to Nemesis, and from it
 Thebes came to be surnamed Asopides. It is
 now called Asopo. 2. In Peloponnesus, which
 runs by Sicyon, and with a north-west course
 falls into the Sinus Corinthiacus, west of Corinth.
 3. In Phrygia Major, which with the Lycus
 washes Laodicea. 4. On the borders of Thes-
 saly, rising in Mount Eta, and falling into the
 Sinus Maliacus.

ASOR, or ASORUS, in ancient geography, 1.
 A town in the south-west of Judah, near Asca-
 lon, called also Hazor, and Hasor-Hadata, trans-
 lated by the seventy *Ασωρη Ταυρη*. 2. A town of
 Galilee; called the capital of all the kingdoms
 north of Palestine. It was taken by Joshua; the
 inhabitants were put to the sword, and their
 houses burnt. It was afterwards rebuilt, but
 remained still in the hands of the Canaanites,
 though in the tribe of Naphthali. It lay north
 of the Lacus Samachonites, called in Scripture
 the waters of Merom.

ASORUS, in ichthyology, a species of the silurus.

ASP, } Gr. *ασπασω*, to tremble, to quiver.
 AS'PEN. } Shaking, trembling; because the
 leaves of the aspen tree tremble with each breath
 of air.

This Sompnour in his stirops high he stood
 Upon this frere his herte was so wood
 That like an aspen leef he quoke for ire.

Chaucer. The Sompnour's Prologue, vi. p. 292.

He to him raught a dagger sharp and keene,
 And gave it him in hand: his hand did quake
 And tremble like a leafe of aspin greene.

Spenser's Faerie Queene, book i. c. ix. s. 51.

The aspen or asp tree hath leaves much the same
 with the poplar, only much smaller, and not so
 white. *Mortimer.*

ASP, } Gr. *ασπις*, a serpent, said to be
 AS'PIK. } peculiar to Egypt and Lybia, whose
 bite is mortal and its effect immediate. Modern
 naturalists have not yet discovered this reptile.

High-minded Cleopatra, that with stroke
 Of asp's sting herself did kill. *Faerie Queene.*

Scorpion, and asp, and amphibæna dire,
 And dipsas. *Milton.*

ASP, ASPIK, thus denominated from the
 Greek, *ασπις*, shield; on account of its lying
 convolved in a circle, in the centre of which is
 the head, which it exerts, or raises, like the umbo
 or umbileus of a buckler. This species of ser-
 pent is very frequently mentioned by authors;
 but so carelessly described, that it is not easy to
 determine which, if any, of the species known at
 present, may probably be called by this name.
 It is said to be common in Africa, and about the
 banks of the Nile; and Bellonius mentions a
 small serpent which he had met with in Italy,
 and which had a sort of callous excrescence on
 the forehead, which he takes to have been the
 aspis of the ancients. It is with the asp that
 Cleopatra is said to have despatched herself, and

prevented the designs of Augustus, who intended to have carried her captive to adorn his triumphal entry into Rome. But the fact is contested. Brown places it among the vulgar errors. The indications of that queen's having used the ministry of the asp, were only two almost insensible pricks found in her arm; and Plutarch says it is unknown of what she died. At the same time it must be observed, that the slightness of the pricks found in her arm furnishes no presumption against the fact; for no more than the prick of a needle-point dipped in the poison was necessary for the purpose of destroying life. Lord Bacon says, the asp is the least painful of all the instruments of death. He supposes it to have an affinity to opium, but to be less disagreeable in its operation; and his opinion seems to correspond with the accounts of most writers, as well as with the effects described to have been produced upon Cleopatra. The ancients had a plaster called *ὁ Ἀσπίδων*, made of this terrible animal, of great efficacy as a discutient of strumæ and other indurations, and used likewise against pains of the gout. The flesh and skin, or exuvie of the creature, had also their share in the ancient materia medica.

ASPA, a town of Parthia, now called Ispahan.

ASPALATHIUS, AFRICAN BROOM, a genus of the decandria order, diadelphia class of plants; ranking in the natural method under the thirty-second order, papilionacæ. The calyx consists of five divisions; the pod is oval, and contains two seeds. Of this genus there are nineteen species; all of which are natives of warm climates, and must be preserved in stoves by those who would cultivate them here. The rose wood, whence the oleum Rhodii is obtained, is one of the species, but of which we have no particular description.

ASPALATHUS, in pharmacy, is also called lignum Rhodium, or rose wood; and by some Cyprus wood: the former on account of its sweet smell, or growth in the island of Rhodes; the latter from its being also found in the island of Cyprus. It was anciently in much repute, as an astringent and strengthener, but is now little used internally. In virtue, taste, smell, and weight, it resembles the lignum aloes; and in physic they are frequently substituted for each other. Aspalathus is chiefly used in scenting pomatums, and liniments.

ASPARAGIN, the name given to white transparent crystals, of a peculiar vegetable principle, which form in asparagus juice after it has been evaporated to the consistence of syrup. They are in the form of rhomboidal prisms, with a slight nauseous taste. They do not change vegetable blues; nor are they affected by hydro-sulphuret of potash, oxalate of ammonia, or acetate of lead; but lime extracts from them ammonia. Along with the asparagin crystals, others in needles of little consistency appear, analogous to mannite, from which the first can be easily picked out.

ASPARAGUS, SPARAGUS, SPERGE, or SPARROW-GRASS, a genus of the monogynia order, and the hexandria class of plants; ranking in the natural method under the eleventh order, sarnen-

tacæ: CAL. quinquepartite, and erect; the three inferior petals bent outwards; the berry has three cells, and contains two seeds. There are ten species; but the only one cultivated in the gardens is the common asparagus, with an upright herbaceous stalk, bristly leaves, and equal stipula. The other species are kept only in the gardens of the curious, for the sake of variety. The garden asparagus is cultivated with great care for the use of the table. The propagation of this useful plant is from seed; and, as much of the success depends upon the goodness of the seed, it is much better to save it than to buy. The manner of saving it is this: Mark with a stick some of the fairest buds; and when they are run to berry, and the stalks begin to dry and wither, cut them up; rub off the berries into a tub, and, pouring water upon them, rub them about with your hands; the husks will break and let out the seed, and will swim away with the water in pouring it off; so that in repeating this two or three times, the seeds will be clean washed, and found at the bottom of the tub. These must be spread on a mat to dry, and in the beginning of February, must be sown on a bed of rich earth. They must not be sown too thick, and must be trod into the ground, and the earth raked over them smooth: the bed is to be kept clear of weeds all the summer; and in October, when the stalks are withered and dry, a little rotten dung must be spread half an inch thick over the whole surface of the bed. Next spring, the plants will be fit to plant out; the ground must therefore be prepared for them by trenching it well, and burying a large quantity of rotten dung in the trenches, so that it may lie at least six inches below the surface of the ground: when this is done, level the whole plot exactly, taking out all the loose stones. This is to be done just at the time when the asparagus is to be planted out; which must be in the beginning of March, if the soil is dry, and the season forward; but in a wet soil, it is better to wait till the beginning of April, which is about the season that the plants are beginning to shoot. The season being now come, the roots must be carefully taken up with a narrow-pronged dung-fork, shaking them out of the earth, separating them from each other, and observing to lay all their heads even, for the more conveniently planting them; which must be done in this manner:—Lines must be drawn, at a foot distance each, straight across the bed; these must be dug into small trenches of six inches deep, into which the roots must be laid, placing them against the sides of the trench, with their buds in a right position upwards, and so that, when the earth is raked over them, they may be two inches under the surface of the ground. Between every four rows, a space of two feet and a half should be left for walking in to cut the asparagus. When the asparagus is thus planted, a crop of onions may be sown on the ground, which will not at all hurt it. A month after this, the asparagus will come up, when the crop of onions must be thinned, and the weeds carefully cleared away. About August the onions will be fit to pull up. In October following, cut off the shoots of the asparagus, within two inches of the ground, clear well all

weeds away and throw up the earth upon the beds, so as to leave them five inches above the level of the alleys. A row of coleworts may be planted in the middle of the alleys, but nothing must now be sown on the beds. In the spring the weeds must be hoed up, and all the summer the beds kept clear of weeds. In October they must be turned up and earthed again, as the preceding season. The second spring after planting, some of the young asparagus may be cut for the table. The larger shoots should only be taken, and these should be cut at two inches under ground, and the beds every year managed as in the second year. But as some people are very fond of early asparagus, the following directions are given, by which it may be obtained any time in winter:—Plant some good roots at one year old in a moist rich soil, about eight inches apart; the second and third year after planting, they will be ready to take up for the hot-beds; these should be made pretty strong, about three feet thick, with new stable dung that has fermented a week or more; the beds must be covered with earth six inches thick; then, against a ridge made at one end, begin to lay in your plants, without trimming or cutting the fibres; and between every row lay a little ridge of fine earth, and proceed thus till the bed is planted; then cover the bed two inches thick with earth, and encompass it with a straw band; and in a week, or as the bed is in the temper, put on the frames and glasses, and lay on three inches thick of fresh earth over the beds, and give them air and add fresh heat to them as it requires. These beds may be made from November till March, which will last till the natural grass comes on.

The roots have a bitterish mucilaginous taste, inclining to sweetness; the fruit has much the same kind of taste; the young shoots are more agreeable than either. Asparagus promotes appetite, but affords little nourishment. It gives a strong ill smell to the urine in a little time after eating it, and for this reason chiefly is supposed to be diuretic; it is likewise esteemed aperient and deobstruent; the root is one of the five called opening roots. Some suppose the shoots to be most efficacious; others, the root; and others, the bark of the root. Stahl is of opinion, that none of them have any great share of the virtues usually ascribed to them. Asparagus appears from experience to contribute very little either to the exciting of urine when suppressed, or increasing its discharge: and in cases where aperient medicines generally do service, this has little or no effect.

ASPASIA, among ancient physicians, a constrictive medicine for the pudenda muliebra. It consisted of wool, moistened with an infusion of unripe galls.

ASPASIA, of Miletus, a courtesan, who settled at Athens under the administration of Pericles, and one of the most noted ladies of antiquity. She was of admirable beauty; yet her wit and eloquence, still more than her beauty, gained her extraordinary reputation among all ranks in the republic. In eloquence she surpassed all her contemporaries; and her conversation was so entertaining, and instructive, that notwithstanding the dishonourable commerce she carried on,

persons of the first distinction, male and female, resorted to her house as to an academy; she even numbered Socrates among her hearers and admirers. She captivated Pericles in such a manner, that he dismissed his own wife, to espouse her; and, by her universal knowledge, irresistible elocution, and intriguing genius, she in a great measure influenced the administration of Athens. She was accused of having excited, from motives of personal resentment, the war of Peloponnesus; yet, calamitous as that long and obstinate conflict proved to Greece, and particularly to Athens, Aspasia occasioned still more incurable evils to both. Her example and instructions, formed a school at Athens, by which her dangerous profession was reduced into a system. The companions of Aspasia served as models for painting and statuary, and themes for poetry and panegyric. Nor were they merely the objects but the authors of many literary works, in which they established rules for the behaviour of their lovers, particularly at table; and explained the art of gaining the heart and captivating the affections. The dress, behaviour, and artifices of this class of women, became continually more seductive and dangerous; and Athens thenceforth remained the chief school of vice and pleasure, as well as of literature and philosophy.

ASPASTICUM, or ASPATICUM, i. e. a greeting-house; from *ασπάζομαι*, I salute; in ecclesiastical writers, an apartment adjoining to the ancient churches, wherein the bishops and presbyters sat to receive the salutations of those who came to visit them, desire their blessing, or consult them.

ASPECT, *v. & n.* Lat. *aspicio, aspectum*, ASPECTABLE, } (from the obsolete word ASPECTED, } *spicere*), to look towards. ASPECT. } The appearance any thing presents when looked at; the point of view; the relation or influence which one thing has or bears with respect to another.

We see likewise the Scripture calleth Envy, an evil eye, and the astrologers call the evil influences of the stars, evil aspects; so that there still seemeth to be acknowledged in the act of envy, an ejaculation or irradiation of the eye. *Lord Bacon's Essays.*
The islands prince, of frame more than celestial,
Is rightly called the all-seeing Intellect;
All glorious bright such nothing is terrestrial;
Whose sun-like face, and most divine aspect,
No human sight may ever hope describe;
For when himself on's self reflects his eye,
Dull and amazed he stands, at such bright majesty.

Fletcher's Purple Island.

If nature's concord broke
Among the constellations war were sprung,
Two planets, rushing from aspect malign
Of fiercest opposition, in mid sky
Should combat, and their jarring spheres confound.

Milton's Paradise Lost, book vi.

Happy in their mistake, those people, whom
The northern pole aspects; whom fear of death
(The greatest of all human fears) ne'er moves.

Temple.

To this use, of informing us what is in this aspect-able world, we shall find the eye well fitted.

Ray on the Creation.

Her motions were steady and composed, and her aspect serious but cheerful; her name was Patience.

Aldous.

Why does not every single star shed a separate influence, and have aspects with other stars of their own constellation?
Bentley's Sermons.

With aspect mild, and elevated eye,
Behold him seated on a mount serene,
Above the fogs of sense and passion's storm:
Wrong he sustains with temper, looks on heaven,
Nor stoops to think his injurer his foe;
Nought but what wounds his virtue wounds his peace.
Young.

ASPECT, in astronomy and astrology, denotes the situation of the planets and stars with respect to each other. There are five different aspects. 1. Sextile aspect is when the planets or stars are 60° distant, and marked thus ✱. 2. The quartile, or quadrate, when they are 90° distant, marked □. 3. Trine, when 120° distant, marked △. 4. Opposition, when 180° distant, marked ○. And, 5. Conjunction, both in the same degree, marked ∪. Kepler, who added eight new ones, defines aspect to be the angle formed by the rays of the two stars meeting on the earth, whereby their good or bad influence is measured; for it is to be observed that these aspects, being first introduced by astrologers, were distinguished into benign, malignant, and indifferent; the quartile and malignant being accounted malign; the trine and sextile, benign or friendly; and the conjunction indifferent.

ASPECT, in gardening, signifies exposure.

ASPECT, DOUBLE, is used in painting, where a single figure is so contrived, as to represent two or more different objects, either by changing the eye, or by means of angular glasses. See OPTICS.

ASPECT, in architecture. The aspect of the principal rooms of a house, demands the greatest attention from the architect, especially in an exposed situation. The south-east is the best for Britain; and the south and due east the next. The south-west is the worst, because from that quarter it rains oftener than from any other. A north aspect is gloomy, because deprived of sunshine; but woods look best when viewed from rooms with a north aspect, because all plants and trees are most luxuriant on the side next the sun. An aspect due east is nearly as bad as the north, because there the sun shines only early in the morning; and the aspect due west is intolerable, from the sun dazzling the eye through the greatest part of the day. Hence we may conclude, a square house placed with its front, opposite to the four cardinal points, will have one good and three bad aspects.

ASPEN or Asp. See POPLAR, of which it is a species. The leaves of this tree always tremble. The aspen or asp tree has leaves much the same with the poplar.

ASPER, in commerce, or aspre, a little Turkish silver coin, wherein most of the Grand Seigneur's revenues are paid. The asper is worth something more than an English halfpenny. The only impression it bears, is that of the prince's name under whom it was struck. The pay of the Janissaries is from two to twelve aspers per diem.

ASPER, in grammar, an accent peculiar to the Greek language, marked thus (´); and importing, that the letter over which it is placed ought to be strongly aspirated, or pronounced as if an *h* were prefixed.

ASPER, in ichthyology, a small fish caught in the Rhone, so called from the roughness of its scales. Its head is large, in proportion to its body, and of a pointed shape. It has no teeth, but its jaws are sharp to the touch. It is of a dark red color, with large black spots. It is good to eat, and is esteemed aperitive.

ASPERA ARTERIA, in anatomy, the windpipe or trachea. See ANATOMY.

ASPERJELLOUS, in botany, the name given by Michaeli to that genus of mosses, called by Dillenius and others, byssus.

ASPERGILE, or ASPERGILIUM, in antiquity, a long brush made of horse-hair, fixed to a handle, wherewith the lustral water was sprinkled on the people in lustrations and purifications. The ancients, instead of a brush, made use of branches of laurel and olive. It is also still applied to the instrument in Romish churches with which holy water is sprinkled.

ASPERIFOLIÆ PLANTÆ, rough-leaved plants. The name of a class in Hermannus, Boerhaave, and Ray's methods, consisting of plants which have naked seeds, and whose leaves are rough to the touch. In Tournefort's system, these plants constitute the third section or order of the second class; and in Linnæus's sexual method, they make a part of the pentandria monogynia.

ASPERIFOLIATE, or ASPERIFOLIOUS, among botanists, such plants as are rough-leaved, having their leaves placed alternately on their stalks, and a monopetalous flower divided into five parts. They constitute the forty-ninth order of plants in the *Fragmenta Methodi Naturalis* of Linnæus, in which are these genera: *tourneortia*, *cerinthe*, *symphytum*, *pulmonaria*, *anchusa*, *lithospermum*, *myosotis*, *heliotropium*, *cynoglossum*, *asperugo*, *lycopsis*, *echium*, *barago*: *magis minusve, oleraceæ, mucilaginosæ, et glutinosæ sunt.*

ASPERITY, the inequality of the surface of any body, which hinders the hand from passing over it freely. From the testimony of some blind persons, it has been supposed that every color hath its particular degree of asperity; though this has been denied by others. See the article BLIND.

ASPERN, a market town, castle, and lordship of Lower Austria, in the circle of lower Mannhartsberg, belonging to the count of Brenner, ten miles south east of Laba.

ASPERN, a market town of Austria, situated on a small arm of the Danube, on the north side of the river, at some distance below Vienna, the scene of a battle fought on the twenty-first and twenty-second of May, 1809, between Buonaparte and the Austrians. It was completely destroyed at the time, but has since been rebuilt.

ASPER/SE, } Lat. *ad*, and *spargo*, to scat-
ASPER/SION. } ter. To sprinkle or scatter;
metaphorically to censure, to calumniate.

In the business of Ireland, besides the opportunity to *asperse* the king, they were safe enough.

Clarendon.

Curb that impetuous tongue; nor rashly vain,
And singly mad, *asperse* the sov'reign reign. *Pope*
Unjustly poets we *asperse*;
Truth shines the brighter clad in verse. *Swift.*

He set his voice

At highest pitch, and thus *aspers'd* the king.

Cæper's Iliad, book vi.

Legions of impure spirits were believed to take often possession of the bodies of men, from whence nothing could drive them but *aspersions* of holy water.

Bolingbroke's Essay on Human Knowledge.

ASPERUGO, small wild bugloss, in botany, a genus of the pentandria monogynia class; ranking in the natural method under the asperifoliae. The calyx of the fruit is compressed, with folds flatly parallel, and sinuous. There are two species, viz. 1. *A. Ægyptiaca*, a native of Egypt. 2. *A. procumbens*, or wild bugloss, a native of Britain; which is eaten by horses, goats, sheep, and swine; but cows are not fond of it.

ASPERULA, **WOODROOF**, in botany, a genus of the monogynia order, and the hexandria class of plants; ranking in the natural method under the forty-seventh order, stellatæ. The corolla is infundibuliform; and the capsule contains two globular seeds. There are two species; which both grow wild in Britain, and therefore are seldom admitted into gardens, viz. 1. *A. cynanchica*, found on chalky hills. The roots are used for dyeing red in Sweden. 2. *A. odorata*, a low umbelliferous plant, growing wild in woods and copses, and flowering in May. It has an exceeding pleasant smell, which is improved by moderate exsiccation; the taste is subsaline, and somewhat austere. It imparts its flavour to vinous liquors. *Asperula* is supposed medicinally to attenuate viscid humors, and strengthen the tone of the bowels; modern practice has nevertheless rejected it.

ASPEYTLA, a town of Spain, in Biscay, seated on the Urola, in a fine valley, near the districts of Loyola and Onis.

ASPHALITES, in anatomy, the fifth vertebra of the loins.

ASPHALTITES, a lake of Judea, so called from the great quantity of bitumen it produces: called also the Dead Sea; and from its situation the East, the Salt Sea, the Sea of Sodom, the Sea of the Desart, and the Sea of the Plain, in the sacred writings. It is enclosed on the east and west with high mountains; on the north it has the plain of Jericho; or, if we take in both sides of the Jordan, it has the Great Plain, properly so called, on the south, which is open, and extends beyond the reach of the eye. Josephus makes this lake 580 furlongs in length, from the mouth of the Jordan to the opposite end, that is about twenty-two leagues; and about 150 furlongs, or five leagues, in its greatest breadth; but our modern accounts commonly give it twenty leagues in length, and six or seven in breadth. On the west side of it is a kind of promontory, where the remains of Lot's metamorphosed wife were for a long time said to be visible. Josephus says this pillar was standing in his time; and Mr. Maundrell was shown a block or stump of it.

In what has been said and written of the Lake Asphaltites, fable is much blended with truth. We are told that it arose from the submersion of the vale of Siddim, where once stood, as is commonly reported, the three cities which perished in the miraculous conflagration, with Sodom and Gomorrah; and this lake has been regarded as a tasting monument of the just judgment of God,

on the abominations for which they perished. It has been stated that its waters are so impregnated with salt, sulphur, and other bituminous matter, that nothing will sink or live in them; and that it emits such a horrid smoke that the very birds die in attempting to cross over it. The description likewise of the apples that grew about it, fair without, and only ashes and bitterness within, were looked upon as a further demonstration of God's anger. Travellers have also described the country round about as sulphureous, bituminous, and suffocating; and it has even been affirmed that the ruins of the five cities are still to be seen through the waters in clear weather.

It appears to be true, that the quantity of salt, alum, and sulphur, with which they are impregnated, render its waters so much specifically heavier (Dr. Pococke says one fifth) than fresh water, that bodies will not easily sink in them: yet that author and others assure us they have swam and dived in it. Dr. Pococke also, though he neither saw fish nor shells, tells us, on the authority of a monk, that fish had been caught in it; and M. Volney affirms that it is very common to see swallows skimming its surface, and dipping for the water necessary to build their nests. The soil around it, he adds, impregnated with salt, produces no plants; and the air itself, which becomes loaded with it from evaporation, and which receives also the sulphureous and bituminous vapours, cannot be favorable to vegetation: hence the deadly aspect which reigns around this lake. In other respects the ground about it, however, is not marshy, and its waters are limpid and incorruptible, as must be the case with a dissolution of salt. On the south-west shore are mines of fossil salt, of which I have brought away several specimens. They are situated on the side of the mountains which extend along that border; and from time immemorial have supplied the neighbouring Arabs, and even the city of Jerusalem. We find also on this shore fragments of sulphur and bitumen, which the Arabs convert into a trifling article of commerce: as also hot fountains and deep crevices, which are discovered at a distance by little pyramids built on the brink of them. Likewise a sort of stone, which on rubbing emits a noxious smell, burns like bitumen, receives a polish like white alabaster, and is used for the paving of court-yards. At intervals we also meet with unshapen blocks, which prejudiced eyes mistake for mutilated statues, and which pass with ignorant and superstitious pilgrims for monuments of the adventure of Lot's wife; though it is no where said she was metamorphosed into stone like Niobe, but into salt, which must have melted the ensuing winter.

This lake is at present called by the Arabs Almotanah and Bahret Lout, and Ula Deguis by the Turks. It is remarkable that but one European has hitherto succeeded in making the circuit of it; and Nau, who in his travels had recorded this expedition of Daniel, abbot of St. Saba, states on his authority, that 'the Dead Sea, at its extremity, is separated as it were into two parts, and that there is a way by which you may walk across it, being only mid-leg deep. at

least in summer; that there the land rises, and bounds another small lake of a circular or rather oval figure, surrounded with plains and mountains of sand, and that the neighbouring country is peopled by innumerable Arabs. Seetzen in the year 1805-6 passed round the southern extremity, but a short account only of his route, in a correspondence with M. de Zach, printed by the Palestine Association in 1810, has yet appeared. Mr. Burckhardt was unable to reach its borders. He was informed in the neighbourhood that there were spots in a ford about three hours north of Szaffye (the extreme southern point of the lake), in which the water is quite hot, and the bottom of red earth. This ford may be crossed in three hours and a half: the water here is generally not more than two feet deep, and it is probable there are hot springs in the bottom. It is so strongly impregnated with salt that the skin peels off the legs of those who wade across it.

M. de Chateaubriand, who visited this country in 1807, has given the first decided testimony that the Lake Asphaltites abounds with fish. He reached it when it was dark, and passed the night among some Arab tents. 'About midnight,' says he, 'I heard a noise upon the lake, and was told by the Bethlehemites, who accompanied me, that it proceeded from legions of small fish, which come out and leap about the shore.' He speaks in the following terms of its saline properties; 'The first thing I did on alighting was to walk into the lake up to my knees, and to taste the water. I found it impossible to keep it in my mouth. It far exceeds that of the sea in saltiness, and produces upon the lips the effect of a strong solution of alum. Before my boots were completely dry they were covered with salt: our clothes, our hats, our hands, were in less than three hours impregnated with this mineral.'

A modern Scottish traveller, Mr. Gordon of Clunie, who bathed in it, brought home a phial of its water, and Dr. Marcet found its specific gravity to be 1.211; a degree of density, says he, 'not to be met with in any other natural water.' The whole process with its results is detailed in the Philosophical Transactions for 1807. It was found that 100 grains of the water contain the following substances in the undermentioned proportions:

	grains.
Muriat of lime . . .	3,920
Muriat of magnesia . . .	10,246
Muriat of soda . . .	10,360
Sulphat of lime . . .	0,054
	<hr/>
	24,580

Another celebrated chemist, M. Klaproth, who procured a specimen brought from the East by the abbé Martin, found the specific gravity to be 1.245 instead of 1.211; agreeing in this respect more nearly with Macquer and Lavoisier, who stated it at 1.240. But the specific gravity of Dr. Marcet's specimen may have been less from its having been taken from the lake not far from the influx of the Jordan, where it might be somewhat diluted.

Dr. Clarke says that the inhabitants of the country still regard the Dead Sea with feelings of terror; owing probably to the tradition that its waters cover the engulfed cities of Sodom and Gomorrah, or to the ideas entertained of the peculiar insalubrity of its exhalations. But it is greatly to be regretted that this traveller was prevented by the Arabs from exploring the lake, which he only saw at a distance.

Hasselquist asserts the apples of Sodom to be the production of the solanum melongena of Linnæus. This is found, he says, in great abundance round Jericho and in the neighbourhood of the Dead Sea. The dust with which it is sometimes filled is the work of an insect (tenthredo) which pulverises the whole of the inside, leaving the rind entire and unchanged in color. M. Seetzen saw at Kerek a species of cotton which he was told was produced from a fruit resembling a pomegranate, growing on the borders of the Dead Sea, and he thinks it is this pulpless fruit which is the malum sodomæum. Viscount Chateaubriand saw a third fruit, which he conjectures to be the famous apples in question, growing on a thorny shrub; and which, before it is ripe is filled with a corrosive and saline juice; when dried it yields a blackish seed, which may be compared to ashes, and which in taste resembles bitter pepper.

ASPHALTUM, BITUMEN JUDAÏCUM, or Jew's Pitch, is a light solid bitumen of a dusky color on the outside, and a deep shining black within; of very little taste, and having scarcely any smell, unless heated, when it emits a strong pitchy one. It is found in a soft or liquid state on the surface of the Dead Sea, and by age grows dry and hard. The same kind of bitumen is met with likewise in the earth in China, America, and in some places of Europe, as the Carpathian Hills, France, &c. The most abundant deposits of this substance, in modern times, are said to be in the islands of Barbadoes and Trinidad; in the former it is found as an highly bituminous earth, but, being in a state of great impurity, is only used as a coal for fuel. In the latter island is a complete lake of this substance. A specimen from Albania of the specific gravity of 1.205, examined by M. Klaproth, was found to be soluble only in oils and in æther. Five parts of rectified oil of petroleum dissolved one of the asphaltum without heat in twenty-four hours; 100 grains of asphaltum afforded 32 of bituminous oil, 6 of water faintly ammoniacal, 30 of charcoal, 7½ of silex, 7½ of alumina, ¾ of lime, 1¼ oxide of iron, ½ oxide of manganese, and 36 cubic inches of hydrogen gas. The true asphaltum was formerly used in embalming the bodies of the dead. At present the thick and solid asphaltum are employed in Egypt, Arabia, and Persia, as pitch for ships; the fluid ones for burning in lamps and for varnishes. Some writers relate that the walls of Babylon and the temple of Jerusalem were cemented with bitumen instead of mortar. This much is certain, that a true natural bitumen, that for instance which is found in the district of Neufchatel, proves an excellent cement for walls, pavements, and other purposes; uncommonly firm, very durable in the air, and not penetrable by water. The watch and clock-makers use a com-

position of asphaltum, fine lamp black, and oil of spike or turpentine, for drawing the black figures on dial-plates; this composition is prepared chiefly at Augsburg and Nuremberg.

ASPHODEL, ASPHODELUS, or KING'S SPEAR, in botany, a genus of the monogynia order, and hexandria class of plants. The calyx is divided into six parts; and the nectarium consists of six valves covering the nectarium. There are five species, viz. 1. *A. albus*, the white asphodel, with keel-shaped leaves, has roots composed of small fibres and knobs at bottom; the leaves are long, almost triangular, and hollow like the keel of a boat; the stalks seldom rise above two feet high, and divide into several spreading branches; these are terminated by loose spikes of white flowers. 2. *A. luteus*, or common yellow asphodel, has roots composed of many thick fleshy fibres, which are yellow, and joined to a head at the top; from whence arise strong round single stalks nearly three feet high, garnished on the upper part with yellow star-shaped flowers, which appear in June, and the seeds ripen in autumn. 3. *A. nonramosus*, or the unbranched asphodel, roots like the ramosus (which see), but the leaves are longer and narrower; the stalks are single; the flowers appear at the same time with the former, are of a purer white, and grow in longer spikes. 4. *A. ramosus*, or branching asphodel, has roots composed of fleshy fibres, to each of which is fastened an oblong bulb as large as a small potatoe; the leaves are long and flexible, having sharp edges; between these come out the flower-stalks, which arise more than three feet high, sending forth many lateral branches. They come out in the beginning of June, and the seeds ripen in autumn. 5. *A. stulosus*, or annual branching spiderwort, hath roots composed of many yellow fleshy fibres; the leaves are spread out from the crown of the root, close to the ground, in a large cluster; these are convex on their underside, but plain above. The flower-stalks rise immediately from the root, and grow about two feet high, dividing into three or four branches upward, which are adorned with white starry flowers, with purple lines on the outside. These flower in July and August, and their seeds ripen in October.

The way to increase these plants is by parting their roots in August, before they shoot up their fresh green leaves. They may also be raised from seeds sown in August; and the August following the plants produced from these may be transplanted into beds, and will produce flowers the second year. They must not be planted in small borders among tender flowers, for they will draw away all the nourishment and starve every thing else. The Lancashire asphodel is thought to be very noxious to sheep, whenever through poverty of pasture they are necessitated to eat it; although they are said to improve much in their flesh at first, they afterwards die with symptoms of a diseased liver. This is the plant of which such wonderful tales have been told by Pauli Bartholine, and others, of its softening the bones of such animals as swallow it; and which they thence called *gramen ossifragum*. Horned cattle eat it without any ill effect.

ASPHURELATA, in natural history, are semi-metallic fossils, fusible by fire, and not malleable in their purest state, being in their native state intimately mixed with sulphur and other adventitious matter, and reduced to what are called ores. Of this series of fossils there are five bodies, each of which makes a distinct genus; viz. antimony, bismuth, cobalt, zinc, and quicksilver.

ASPHYXIA; from α privative, and $\sigma\upsilon\phi\chi\iota\varsigma$, a pulse; in medicine, the state during life in which the pulsation of the heart and arteries cannot be perceived. Medical writers usually divide this suspended animation into lipothymia, apoplexia, syncope, submersio, suspensio, and congelatio. Mr. Sage has published a treatise recommending the volatile alkali fluor as the most effectual remedy in asphyxies. Asphyxia is also used by some for a privation of pulse in a part of the body, e. g. in the arm, &c.

The following extraordinary case of asphyxia is related by Dr. Cheyne, in his *English Malady*, p. 307. 'Case of the Hon. Colonel Townshend.—Col. Townshend, a gentleman of excellent natural parts, and of great honor and integrity, had for many years been afflicted with a nephritic complaint, attended with constant vomitings, which had made his life painful and miserable. During the whole time of his illness he had observed the strictest regimen, living on the softest vegetables, and lightest animal foods, drinking asses milk daily, even in the camp; and for common drink, Bristol water, which the summer before his death he had drank on the spot. But his illness increasing, and his strength decaying, he came from Bristol to Bath in a litter, in autumn, and lay at the Bell-inn. Dr. Baynard (who is since dead) and I were called to him, and attended him twice a day for about the space of a week, but his vomitings continuing still incessant and obstinate against all remedies, we despaired of his recovery. While he was in this condition he sent for us early one morning: we waited on him with Mr. Skrine, his apothecary, (since dead also); we found his senses clear and his mind calm, his nurse and several servants were about him. He had made his will and settled his affairs. He told us he had sent for us to give him some account of an odd sensation he had, for some time observed and felt in himself; which was that, composing himself, he could die or expire when he pleased, and yet, by an effort or some how, he could come to life again; which it seems he had sometimes tried before he had sent for us.

'We heard this with surprise; but as it was not to be accounted for from any common principles, we could hardly believe the fact as he related it, much less give any account of it, unless he should please to make the experiment before us, which we were unwilling he should do, lest in his weak condition he might carry it too far. He continued to talk very distinctly and sensibly above a quarter of an hour about this (to him) surprising sensation, and insisted so much on our seeing the trial made, that we were at last forced to comply. We all three felt his pulse first; it was distinct, though small and thready; and his heart had its usual beating. He composed him-

self on his back, and lay in a still position some time; while I held his right hand, Dr. Baynard laid his hand on his heart, and Mr. Skrine held a clear looking-glass to his mouth. I found his pulse sink gradually, till at last I could not feel any by the most exact and nice touch. Dr. Baynard could not feel the least motion in his heart, nor Mr. Skrine the least soil of breath on the bright mirror he held to his mouth; then each of us by turns examined his arm, heart, and breast; but could not, by the nicest scrutiny, discover the least symptom of life in him. We reasoned a long time about this odd appearance as well as we could, and all of us judging it inexplicable and unaccountable, and finding he still continued in that condition, we began to conclude that he had indeed carried the experiment too far, and at last were satisfied he was actually dead, and were just ready to leave him. This continued about half an hour, by nine o'clock in the morning, in autumn. As we were going away we observed some motion about the body, and, upon examination, found his pulse and the motion of his heart gradually returning; he began to breathe gently, and speak softly; we were all astonished to the last degree at this unexpected change, and after some further conversation with him, and among ourselves, went away fully satisfied as to all the particulars of this fact, but confounded and puzzled, and not able to form any rational scheme that might account for it. He afterwards called for his attorney, added a codicil to his will, settled legacies on his servants, received the sacrament, and calmly and composedly expired about six o'clock that evening. Next day he was opened (as he had ordered); his body was the soundest and best made I had ever seen; his lungs were fair, large, and sound, his heart big and strong, and his intestines sweet and clean; his stomach was of a due proportion, the coats sound and thick, and the villous membrane quite entire; but when we came to examine the kidneys, though the left was perfectly sound and of a just size, the right was about four times as big, distended like a blown bladder, and yielding as if full of pap; he having often passed a wheyish liquor, after his urine, during his illness. Upon opening this kidney we found it quite full of a white chalky matter, like plaster of Paris, and all the fleshy substance dissolved and worn away by what I called a nephritic cancer. This had been the source of all his misery; and the symptomatic vomitings, from the irritation on the consentient nerves, had quite starved and worn him down. I have narrated the facts as I saw and observed them, deliberately and distinctly, and shall leave the philosophic reader to make what inferences he thinks fit. The truth of the material circumstances I will warrant.

ASPER, in botany, a plant which grows in plenty in Languedoc, in Provence, and especially on the mountain of St. Baume in France. It is a kind of lavender, nearly like what grows in our gardens, both with regard to the figure and color of its leaves and flowers. The botanists call it *lavendula mas*, or *spica nardi*, *pseudo nardus*, &c.

ASPHATES, or **ASPHENITHS**, in the writings

of the ancients, the name of a stone, famous for its virtues against the spleen, and many other disorders; it was to be applied externally, and fastened to the part with camel's hair.

ASPINY, or **ANGLIARY-THORN**, a drug used in medicine, on which particular duties are imposed by the tariff of the custom-house at Lyons.

ASPIRE',
ASPIR'ANT,
ASPIR'ATE, *v. n. & adj.*
ASPIR'ATION,
ASPIRE'MENT,
ASPIR'ER,
ASPIR'ING.

Aspiro; from *ad*, and *spiro*; to breathe; to search after diligently, and in consequence of the arduous exertion to breathe frequently, and with apparent difficulty; to pant after; to pursue with eagerness an object deemed worthy of our ambition; to desire with eagerness. To aspirate is to breathe strongly upon a letter in sounding it.

'Tis he; I ken the manner of his gait:
 He rises on his toe; that spirit of his
 In aspiration lifts him from the earth.

Shakspeare.

Horace did ne'er *aspire* to epic bays;
 Nor lofty Maro stoop to lyric lays.

Roscommon.

Till then a helpless, hopeless, homely swain;
 I sought not freedom, nor *aspired* to gain.

Dryden.

Aspiring to be gods, if angels fell,
Aspiring to be angels, men rebel.

Pope.

H is only a guttural *aspiration*, i. e. a more forcible impulse of the breath from the lungs.

Holder.

A soul inspired with the warmest *aspirations* after celestial beatitude, keeps its powers attentive.

Watts.

Know thine own worth, and reverence the lyre.

Wilt thou debase the heart which God refined?

No! let thy heaven-taught soul to heaven *aspire*,

To fancy, freedom, harmony, resign'd;

Ambition's groveling crew for ever left behind.

Beattie's Minstrel.

Some more *aspiring* catch the neighbouring shrub,
 With clasping tendrils, and invest her branch.

Cowper.

Ye stars! which are the poetry of heaven!
 If in your bright leaves we would read the fate
 Of men and empires,—'tis to be forgiv'n,
 That in our *aspirations* to be great,
 Our destinies o'erleap their mortal state,
 And claim a kindred with you;

Lord Byron's Child Harold.

ASPIUS, in ichthyology, a species of the cyprinus, belonging to the abdominal order. It is met with in the lakes of Sweden.

ASPORTATION. Lat. *ad*, and *porto*, to carry; a carrying to.

A bare removal from the place in which he found the goods, though the thief does not quite make off with them, is a sufficient asportation or carrying away.

Blackstone.

ASPOTAGOEN MOUNT, a sea-mark on the coast of Nova Scotia, from which ships bound from Europe to Halifax generally look out. It rises on the promontory, between Mahone and Margaret's bay, to about 500 feet above the level of the sea.

ASPRE,
ASPRELY,
ASPRENESS,
ASPERATE,
ASPERITY,
ASPEROUS.

Lat. *asper*, rough in its nature; applied to that which is harsh, rugged, grating, bitter, morose.

Black and white are the most *asperous* and unequal of colours; so like, that it is hard to distinguish them: black is the most rough. *Boyle.*

I hope it is no very cynical *asperity*, not to confess obligations where no benefit has been received, or to be unwilling that the public should consider me as owing to a patron, that which Providence has enabled me to do for myself. *Dr. S. Johnson.*

The patience of Job is proverbial. After some of the convulsive struggles of our irritable nature, he submitted himself, and repented in dust and ashes. But even so, I do not find him blamed for reprehending, and with a considerable degree of *asperity*, those ill-natured neighbours of his who visited his dunghill to read moral, political, and œconomical lectures on his misery. *Burke.*

ASP'Y, *v. & n.* See ESPY.

In due season, as she always *aspied*
Every thing to execute conveniently,
The one lower first friendly she cied,
The second she offered the cuppe curtesly.

Chaucer. The Rein of Loue.

For Ion seide to Eroute, it is not leueful to thee to have the wyf of thi brother, and Erodias leide *aspies* to him and wolde sle him and myghte not.

Wiclif. Mark, ch. vi.

ASRAEL, the angel, according to the Mahomedan system, who is appropriated to take care of the souls of those who die.

ASS,

AS'INE, } Lat. *asinus*, a well known animal.
ASS'LIKE. }

You have among you many a purchas'd slave;

Which, like your *asses* and your dogs and mules,

You use in abject and in slavish part,

Because you bought them.

Shakspeare.

You shall have more ado, to drive our dullest youth, our stocks and stubs, from such nurture; than we have now, to hale our choicest and hopefullest wits, to that *asinine* feast of sow-thistles and brambles. *Milton.*

Ass, in zoology. See EQUUS.

ASS, CORONATION OF THE, in antiquity, was a part of the ceremony of the feast of Vesta, wherein the bakers put crowns on the heads of these quadrupeds; Ecce coronatis panis dependet asellis! Hence, in an ancient calendar, the ides of June are thus denoted: Festum est Vestæ. *Asinus coronatur!* This honor it seems was done the beast, because, according to the mythology, by its braying it had saved Vesta from being ravished by the Lampsacan god. Hence the formula, *Vestæ delicium est asinus.*

ASSAC, or ASSAX, in the materia medica of the ancients, the name given by the Arabians to the gum ammoniac of the Greeks; but by many of the qualities attributed to this drug it does not appear to be the same that is now called so.

ASSACH, or ASSATH, a kind of purgation, anciently used in Wales, by the oaths of 300 men.

ASSAI, in music, signifies quick; or, according to others, that the motion of the piece be kept in a middle degree of quickness or slowness: as, *assai allegro*, *assai presto*. See ALLEGRO and PRESTO.

ASSAIL', } Fr. *assailir*, Lat.
ASSAIL'ABLE, } *adsalire*, to leap upon.
ASSAIL'ANT, *v. & adj.* } To assault; to make a
ASSAIL'ER, } sudden and vehement
ASSAIL'MENT, } attack by various means
of annoyance.

So, when he saw his flatt'ring arts to fail,
With greedy force he 'gan the fort t' *assail*.

Færie Queene

I'll put myself in poor and mean attire,
And with a kind of umber smirch my face;
The like do you: so shall we pass along,
And never stir *assailants*.

Shakspeare.

My gracious lord, here in the parliament
Let us *assail* the family of York. *Id.*

She will not stay the siege of loving terms,
Nor bide th' encounter of *assailing* eyes. *Id.*

How have I fear'd your fate! but fear'd it most,
When love *assail'd* you on the Libyan coast. *Dryde..*

Prompt to *assail* and careless of defence,
Invulnerable in his impudence;
He dares the world; and eager of a name,
He thrusts about, and jostles into fame.

Id. Hind and Panther.

All books he reads, and all he reads *assails*,
From Dryden's *Fabies* down to D—y's *Tales*.

Pope.

Sensible of their own force, and allured by the prospect of so rich a prize, the northern barbarians, in the reign of Arcadius and Honorius, *assailed* at once all the frontiers of the Roman empire. *Hume.*

When winds the mountain oak *assail*,

And lay its glories waste,

Content may slumber in the vale,

Unconscious of the blast.

Beattie.

ASSAM, or ASHAM, a country between Bengal and Thibet, 700 miles in length, by about 70 in breadth. It is intersected by the Brahmapoetra and several rivers. On the north it is bounded by the mountains of Bootan and Thibet, on the south by the Garrow mountains, on the west by Bengal and Bisnee, and on the east by the tributaries of Ava and China. Assam is very fertile, and produces a considerable quantity of gold, found in the beds of the rivers; it also yields ivory, lac, pepper, silk, and cotton, and exports a considerable quantity of borax and musk, said to be procured from Bootan and Thibet. Its imports from Bengal are principally salt, various European commodities, and a few fine muslins. The inhabitants are genuine Hindoos, and are very shy of permitting foreigners to come among them. During the period that the Afghans and Moguls had possession of Bengal they frequently invaded this country, and even took possession of Ghergong the capital, but the unhealthiness of the climate compelled them always to retire with great loss. In the year 1793 a detachment of the East India Company's troops, under the command of Colonel Welsh, entered Assam for the purpose of reinstating the rajah Surjee Deo; and, in consequence of the services then rendered him, the rajah established a reciprocal liberty of commerce between himself and the British; and it was finally agreed that no European merchant or adventurer, of any description, should be allowed to fix his residence in Assam, without having previously obtained the permission of the British government, and of Maha Rajah Surjee Deo, of Assam.

ASSANCALA, or ASSANCALE, a strong town in Armenia, near the river Arras, in the road between Erzerum and Erivan, noted for its hot baths. It stands on a high hill, twenty-two miles east of Erzerum; the walls are built in a spiral line all round the rock, and strengthened

with square towers. The ditches are about two fathoms over, cut out of hard rock.

ASSAPOORY, in natural history, a name given by the people of the East Indies to a peculiar species of slate, which they use in medicine, reducing it to powder, and strewing it on burning coals that the sick person may receive the fumes of it. It is principally used for children when they are disordered by taking cold. The smell of it, while burning, is very offensive.

ASSARIUM, a small copper coin, being a part of the as. The word is used by Suidas indifferently with *οβολος*, and *νομισμα*, to denote a small piece of money; in which he is followed by Cujacius, who defines *ασσαριον*, by *minimus æris nummus*. We find mention of the assarion in Matthew, chap. x. ver. 29., translated a farthing.

ASSARON, an ancient Jewish measure of capacity, equal to the tenth part of an ephah. The assaron is the same with the omer. Josephus calls it *ασσαρον*; in the Hebrew it is written assarith. It was the measure of manna appointed for each person.

ASSAS'SIN, *v. & n.* } The etymology of
ASSAS'SINACY, } this word has given
ASSAS'SINATE, *v. & n.* } rise to much learned
ASSASSINATION. } discussion, and the
question is still undecided. Applied to one who attacks and kills those unprepared for defence, by treachery, or sudden violence.

It were done quickly; if th' *assassination*
Could trammel up the conscience. *Shakspeare.*

Such usage as your honourable lords
Afford me, *assassinated* and betray'd;
Who durst not, with your whole united pow'rs,
In fight withstand one single and unarm'd.

Milton.

The Syrian king; who, to surprise
One man, *assassin* like, had levy'd war,
War unproclaim'd.

Id.

The duke finished his course by a wicked *assassination*.
Clarendon.

In the very moment, as the knight withdrew from the duke, the *assassinate* gave him, with a back blow, a deep wound into his left side. *Wotton.*

The old king is just murdered; and the person that did it is unknown—Let the soldiers seize him, for one of the *assassinates*; and let me alone, to accuse him afterwards. *Dryden.*

Here hired *assassins* for their gain invade;
And treach'rous pois'ners urge their fatal trade.

Creech.

When she hears of a murder, she enlarges more on the guilt of the suffering person, than of the *assassin*. *Addison.*

Orestes brandish'd the revenging sword;
Slew the dire pair; and gave to fun'ral flame
The vile *assassin*, and adult'rous dame,
Useful, we grant; it serves what life requires;
But, dreadful too, the dark *assassin* hires.

Id.

ASSASSINS, a tribe or clan in Syria, called also Ismaelians and Batenists, or Batenians. These people probably owed their origin to the Karmatians, a famous heretical sect among the Mahomedans, who settled in Persia about the year 1090; whence, in process of time, they sent a colony into Syria, where they became possessed of a considerable tract of land among the mountains of Lebanon, extending itself from the neighbourhood of Antioch to Damas-

cus. The first chief and legislator of this extraordinary tribe was Hassan Sabah, a subtle impostor; who, by his artifices, made fanatical and implicit slaves of his subjects. Their religion was compounded of that of the Magi, the Jews, the Christians, and the Mahomedans: but the capital article of their creed was to believe that the Holy Spirit resided in their chief; that his orders proceeded from God himself, and were real declarations of the divine pleasure.

To this monarch the orientals gave the name of Scheik; but he is better known in Europe by the name of the Old Man of the Mountain. This chief, from his residence on mount Lebanon, sent, like a vindictive deity, inevitable death to all quarters of the world; and many sovereigns paid secretly a pension to the Scheik, for the safety of their persons. The Knights Templars alone dared to defy his secret machinations and open force. Indeed, they were a permanent dispersed body, not to be cut off by massacres or assassinations. In 1090, Mâlek Shâh, third sultan of the Seljukians, of Iran, sent a messenger to Hassan, the Old Man of that period, calling on him for obedience, and accompanying the demand with threats in the case of his refusal. Hassan desired the ambassador might be admitted; and having assembled around him his troops, commanded one of them to draw his dagger, and plunge it into his own breast; the man, without the slightest hesitation, stabbed himself to the heart, and fell dead at his sovereign's feet. He then commanded a second to precipitate himself from the nearest tower; and was instantaneously obeyed. 'Go,' said Hassan, 'to the sultan, your master, and inform him, that I have no other reply to make him, excepting that I have seventy thousand troops equally obedient with those you have this day witnessed.' The sultan took the hint; and having, as Ebn Amed states, other matters in his hands, thought it not advisable to prosecute a war against this prince.

In 1192, the assassins penetrated the palace of Courade, marquis of Montserrat, who had displeased them, and put him to death. In 1213, they assassinated Lewis of Bavaria. Hulakn, a khan of the Mogul Tartars, in the year 655 of the Hegira, or 1254 of the Christian era, entered their country, and dispossessed them of several places. In 1257, the Tartars conquered them and killed their prince; but it was not till 1272, that they were totally extirpated; an achievement owing principally to the conduct and intrepidity of the Egyptian forces sent against them by the sultan Bibaris.

by the parliament, which produced its dissolution, there followed a composure. *Clarendon.*

Theories built upon narrow foundations, are very hard to be supported against the assaults of opposition. *Locke.*

The king granted the Jews, to gather themselves together, and to stand for their life, to destroy all the power, that would assault them. *Esther*, viii. 11.

Before the gates, the cries of babes new-born, Whom fate had from their tender mothers torn, Assault his ears. *Dryden.*

Now cursed steel, and more accursed gold, Gave mischief birth, and made that mischief bold; And double death did wretched man invade, By steel assaulted, and by gold betray'd. *Id.*

Neither liking their eloquence, nor fearing their might, we esteemed few swords, in a just defence, able to resist many unjust assaulters. *Sidney.*

This just rebuke inflamed the Lycian crew, They join, they thicken, and th' assault renew; Unmov'd th'embodied Greeks their fury dare, And fix'd, support the weight of all the war. *Pope. Homer's Iliad*, xii. 505.

ASSAULT, in law, is an attempt to beat another, and may be committed without touching him: as if one lifts up his cane or fist in a threatening manner at another; or strikes at him, but misses him; this is an assault, insultus, which Finch describes to be 'an unlawful setting upon one's person.' This also is an inchoate violence, amounting considerably higher than bare threats; and, therefore, though no actual suffering is proved, yet the party injured may have redress by action of trespass vi et armis, wherein he shall recover damages as a compensation for the injury.

ASSAULT, in the military art, a furious effort made to carry a fortified post, camp, or fortress, wherein the assailants do not screen themselves by any works: while the assault continues, the batteries cease, for fear of killing their own men.

ASSAY, *v. & n.* Fr. *essayer*, Ital. *assaggiare*, to try, examine, prove; to submit to experiment; to test.

One, that to bounty never cast his mind;
No thought of honour never did assay
His baser breast. *Spenser.*
She heard with patience all, unto the end;
And strove, to master sorrowful assay. *Faerie Queene.*

Gray and Bryan obtained leave of the general, a little to assay them; and so, with some horsemen, charged them home. *Hayward.*

What unweighed behaviour hath this drunkard picked out of my conversation, that he dares in this manner assay me? *Shakespeare.*

Be sure to find,
What I foretell thee; many a hard assay
Of dangers, and adversities, and pains,
Ere thou of Israel's sceptre get fast hold. *Milton.*
The men he prest but late
To hard assays unfit, unsure y need;
Yet arm'd to point, in well attempted plate. *Faerie Queene.*

She thrice assay'd to speak; her accents hung,
And fal'ring dy'd unfinish'd on her tongue,
Or vanish'd into sighs: with long delay
Her voice return'd; and found the wonted way. *Dryden's Fables.*

ASSAYING, or ESSAYING, in metallurgy, is a method of ascertaining the actual quantity of pure gold or silver in a given metallic mass.

The term might, with equal propriety, be applied to ascertaining the presence and quantity of any metal, perfect or imperfect, in a mass of ore: but it has, from the universal value of the pure or precious metals, been gradually appropriated to the best modes of separating them from all admixture, the baser metals being considered by the assayer as of no value or consideration. We thus, therefore, apply the term in this paper; referring to the article METALLURGY, and the names of other metallic ores, in their alphabetical places, for more general observations.

Assaying is a species of chemical analysis, owing its origin probably, like the rest of the modern terms of chemistry, to the alchemy of darker ages. In this country the Liber Niger Scacarii, cited by Du Cange, attributes the first assay of money to the bishop of Salisbury, a royal treasurer, in the reign of Henry I. It states, that if the examined money was found to be deficient above sixpence in the pound, it was not deemed lawful money of the king, Du Cange, Gloss. i. p. 343. And thus is explained the first application of the terms *arsas* and *arsuram*, to money, in the Exchequer-book. But, it is clear, that some species of assay was practised by our ancestors as early as the Norman conquest, Domesday-book expressly stating, vol. i. f. 15, 16, that £65 of coined money was only worth £50 in pure silver, 'according to the assay of the Mint.' This is the passage: 'Totum manerium T. R. E. et post valuit xl. libras. Modo similiter xl. lib. Tamen reddit 2 lib. ad arsuram et pensum quæ valent lxx. lib.' It also appears, by the same authority, that the king had this right of assay in several places beside the capital. It is remarkable, as Mr. Turner has observed, that we have no Anglo-Saxon gold coins, though numerous silver coins of that period have come down to us. That learned historian thinks, that both gold and silver uncoined, were, however, in circulation at this date. According to Dr. Henry's account of the conduct of Henry VIII. in respect to the coinage, it became indeed, most important that some system should be adopted for regulating the standard value of our coins.

'That monarch,' he remarks, 'after he had squandered all his father's treasures, the grants he had received from parliament, and the great sums he had derived from the dissolution of the religious houses, began to diminish his coins both in weight and fineness. This diminution at first was small, in hopes, perhaps, that it would not be perceived; but, after he had got into this fatal career, he proceeded by rapid steps to the most pernicious lengths. In the thirty-sixth year of his reign, silver money of all the different kinds was coined, which had only one-half silver and the other half alloy. He did not even stop here; in the last year of his reign, he coined money that had only four ounces of silver and eight ounces of alloy in the pound weight; and the nominal pound of this base money was worth only 9s. 3½d. of our present money. He began to debase his gold coins at the same time, and proceeded by the same degrees. But it would be tedious to follow him in every step. In this degraded and debased condition Henry

the Eighth left the money of his kingdom to his son and successor Edward the Sixth. This shameful debasement of the money of his kingdom, was one of the most imprudent, dishonorable, and pernicious measures of his reign: it was productive of innumerable inconveniences and great perplexity in business of all kinds; and the restoration of it to its standard purity was found to be a work of great difficulty,' Henry's History of Great Britain, vol. xii. p. 336, 337. It is worthy of observation, that since that period, we have had no such capricious and nefarious attempts; and the regulations of the royal British Mint may now be quoted as at once most scientific and effective.

The art, to which this paper is devoted, consists of two distinct branches or operations, the separation of alloy, or base metals, from the precious ores, accomplished by what is technically called cupellation; and the separation of the precious metals, gold, platina, and silver from each other, called quartation and parting.

The separation of gold, silver, and platina, from baser metals, is conducted by exposing the whole metallic mass, in which they are supposed to be contained, mixed with a certain portion of lead, to a strong heat, in a shallow crucible, made of burned bones, called a cupel; which is placed in a muffle or small earthen oven, fixed in the midst of a furnace. The lead now vitrifies, or becomes converted into a glassy calx, which dissolves the imperfect metals: and this calx, with those metals which it absorbs, soaks into the cupel, and leaves the precious metals in a state of purity. 'In proportion to the violence of the heat,' says Dr. Aikin, 'is the density of the fume, the violence with which it is given off, the convexity of the surface of the globule of melted matter, and the rapidity with which the vitrified oxide circulates (as it is termed), or falls down the sides of the metal. As the cupellation advances, the melted button becomes rounder, its surface becomes streaky with large bright points of the fused oxide, which moves with increased rapidity, till at last the globule, being now freed from all the lead and other alloy, suddenly lightens; the last portions of litharge on the surface disappear with great rapidity; showing the melted metal bright with iridescent colors, which directly after becomes opaque, and suddenly appears brilliant, clean, and white, as if a curtain had been withdrawn from it. The operation being now finished, and the silver left pure, the cupel is allowed to cool gradually, till the globule of silver is fixed, after which it is taken out of the cupel while still hot, and when cold weighed with as much accuracy as at first. The difference between the globule and the silver at first put in, shows the quantity of alloy, the globule being now perfectly pure silver, if the operation has been well performed. The reason of cooling the globule or button gradually is, that pure

silver, when congealing, assumes a crystalline texture, and if the outer surface is too suddenly fixed, it forcibly contracts on the still fluid part in the centre, causing it to spurt out in arborescent shoots, by which some minute portions are often thrown out of the cupel, and the assay spoiled.'

The assay of gold and silver is alike, it will be observed, throughout the process of cupellation. As lead is the medium required for the absorption of other metals, both the quality and quantity of that metal employed become important to ascertain. If it contains much silver, it will be easy to perceive a source of material error in the operations of the assayer. Lead revived from litharge contains only about half a grain in the pound weight, and is therefore preferred to lead immediately revived from the ore, which usually contains a larger quantity.

As to the proper quantity of lead, it is desirable at first to ascertain the comparative state of purity of the ingot to be assayed. In this country, such a judgment is generally formed from inspection of the color, hardness, tenacity, &c. of the metal, but formerly touch-needles were employed for this purpose. These, which are not entirely in disuse, consist of small bars of differently proportioned alloys, of known composition. If a streak is made with the ingot upon the surface of black flint, or basalt, a species of indurated slate, called by the ancients *βάσανος*, and still known by the name of basanite, or even upon a fragment of black pottery, by comparing the streaks with those made on the same stone from needles of known composition, the relative purity of the ingot may be inferred. 'Copper' says Dr. Aikin, 'the usual alloy of the fine metals, when taken singly, is found to require from ten to fourteen times its weight of lead for complete scorification on the cupel. Now, all admixtures of fine metal tend to protect the copper from the action of the litharge and the more obstinately, the greater the proportion of fine metal. So that copper, with three times its weight of silver (or 9 oz. fine), requires forty times as much lead as copper; with eleven parts of silver it requires seventy-two parts of lead, and the like in an increasing ratio. The following is the table of the proportions of lead required to different alloys of copper; of which a few points are founded on the above-mentioned experiments, and the rest filled up according to the estimated ratio of increase, being multiples of the assy integer 24 in arithmetical progression. In the three first columns is shown the absolute increase of the quantity of lead in alloys of decreasing fineness; in the three last columns will be seen the gradual diminution of the protecting power of fine metal against scorification, in proportion to the increase of alloy, shown by the decreasing quantity of lead required for the same weight of copper, under different mixtures.'

TABLE.

Silver		Copper		Lead	Ratio of increase		Copper		Silver		Lead
23	with	1	requires	96	= 4 × 24	and hence	1	with	23	requires	96
22		2		144	= 6 × 24		1		11		72
20		4		192	= 8 × 24		1		5		48
18		6		240	= 10 × 24		1		3		40
16		8		288	= 12 × 24		1		2		36
14		10		336	= 14 × 24		1		1½		33
12		12		384	= 16 × 24		1		1		32
10		14		432	= 18 × 24		1		¾		30
8		16		480	= 20 × 24		1		½		30
6		18		528	= 22 × 24		1		¼		29
4		20		576	= 24 × 24		1		⅓		28
2		22		624	= 26 × 24		1		⅕		28

It should be remarked, however, that many assayers of good authority use proportions of lead considerably different from the above table; and the whole of the numbers here given may be considered as rather high, in regard to the quantity of lead. The assaying of gold, if that noble metal contained copper as an alloy, would be as simple and expeditious as that of silver; but all gold contains a portion of silver, which cannot be destroyed by cupellation: it may also contain platina; but this is not commonly found.

After it has passed the cupel, quartation and parting become necessary. The former consists in adding (generally) three parts of silver to the mass of supposed gold, and fusing them together. It is an object of importance to prevent the cornets from being broken, the result being less likely to be accurate when the gold is in fragments; and to prevent this, the quantity of silver used is no more than is absolutely necessary, it being found that the less the quantity of gold, compared to the silver, used in the assay, the more likely is the gold to be broken into pieces. 'Suppose, for example,' says Mr. Mushet, 'that a gold assay is made from the integer, or pound, weighing twelve grains Troy, an addition of from twenty-four to thirty-six grains of pure silver is made in addition to the small portion already supposed to exist in the mass. This becomes thoroughly incorporated with the gold in the process of cupellation. The globule, or button, as soon as it is taken from the furnace, is passed between a pair of polished steel rollers, and drawn out into a thin lamina, or plate, of the thickness of a sixpence, and returned into the furnace to be annealed. After being kept in a red heat for some time, it is taken out and suffered to cool. It is then wound up into a cornet. This is put into a glass matrass, of the shape of an inverted cone, and with about twice or thrice its weight of very pure nitric acid. M. Vauquelin recommends it to be 1:25 specific gravity.'

The hot acid being very carefully poured from the matrass, warm water is added to wash any remains of silver from the gold, and the addition repeated until the water comes off perfectly clear. The cornets of gold, which are of a dull brown color, are then put according to their numbers

into small clay crucibles, into which they are allowed gently to fall by inverting the matrass, with a portion of water in it, which breaks their fall, and also collects any grains of gold that may be in the matrass. The water is then poured off, and they are put into the furnace, and annealed under a bright cherry heat. When cooled, the pieces of gold exhibit their beautiful characteristic lustre, and possess all the softness and flexibility of that metal. The weight of the original metallic mass before cupellation and in the subsequent stages, compared with the final weight now ascertained, indicates the degree of fineness of the ingot, or ore, of which it is a part. In estimating or expressing this fineness in regard to gold, the whole mass spoken of is supposed to weigh twenty-four carats of twelve grains each, either real, or merely proportional, like the assayer's weights; and the pure gold is called fine. Thus, if gold be said to be twenty-three carats fine, it is to be understood, that in a mass weighing twenty-four carats, the quantity of pure gold amounts to twenty-three carats.

The assay report of gold, says the official gentleman we have quoted above, is made according as it is better or worse than standard. The standard of our gold coin is twenty-two carats fine, and two carats alloy. If, by assay, an ingot of gold was found to contain twenty-one carats of fine gold, it would be reported worse one carat, the mass containing a carat of alloy more than the proportion of two carats to twenty-two carats fine. If the ingot weighed fifteen pounds Troy, there would be deducted from the gross weight one carat, or 240 grains Troy, reducing the standard of the mass to 14 lbs. 11 ozs. 10 dwts. If, on the contrary, the mass was found to contain twenty-three carats fine gold, it would be reported one carat better than standard; and this carat would be added to the gross weight of the ingot, which we have supposed to weigh fifteen pounds Troy, and would be called 15 lbs. 0 oz. 10 dwts. of standard gold. When the gold assay pound or integer is only twelve grains, the quarter assay grain weighs only ¼ part of a Troy grain. This will show how delicate the scales must be by which the assayer works in order to obtain accuracy. In the royal mint the scales of the assayers will be sensibly affected even with

the $\frac{1000}{1000}$ th part of a Troy grain. When the emperor of Russia lately visited the mint, he was particularly struck with the extreme delicacy of the assay scales of Mr. Bingley, the king's assayer. That gentleman requested the favor of his imperial majesty to put one of the hairs of his head into the scale, which he did, and, to the great satisfaction of his majesty, it very sensibly affected the equilibrium of the beam.'

It is necessary to be careful that the silver used in this last process should contain no gold, otherwise a source of material error would arise in the operation; and, as silver generally contains a small portion of gold, the best assayers use that which is revived from a precipitation of the nitrate of silver. This nitrate of silver is precipitated by immersing in it plates of copper: it may also be recovered by a solution of common salt, which converts the silver into luna cornea, of which, when washed and well dried, 100 parts contain seventy-five of silver. The accuracy of the assay may also be proved by this process. The luna cornea, however, is more difficult to reduce to the metallic state.

Many dealers in bullion (the bank of England we believe uniformly) refuse to purchase any foreign gold bullion, until it has been remelted by refiners or melters on whose integrity they can rely.

Platina, on account of its great value, is not likely to be used in debasing silver; but it may be fraudulently added to gold. Like gold and silver, it resists the action of lead upon the cupel; but an expert assayer will recognise its presence by the very different appearance which it gives to the button of metal in fusion. This is less perfect; a much greater heat is required; and the color less bright; and, in a very small proportion, it gives to the gold a strong tendency to crystallisation. Nothing is required for its separation but to proceed exactly as in a gold assay; and, by reducing the lamina of metal very thin, to form the cornet, the platina, though alone insoluble in nitric acid, may, with the silver, be totally removed from the gold.

Some idea of the delicacy required through the whole of the foregoing operations may be formed from an authentic statement, that in our national mint an assay of twenty grains is relied on for giving the value of a mass of gold of fifteen pounds, or of silver of sixty pounds in weight.

The *Annales de Chimie*, vol. vi. p. 64, contain some very interesting details of recent attempts of the French government to establish an accurate assay of gold. The general result is as follows, nearly in the terms of the experimenters:—

Six principal circumstances appear to affect the operation of parting: namely, the quantity of acid used in parting, or in the first boiling; the concentration of this acid; the time employed in its application; the quantity of acid made use of in the reprise, or second operation; its concentration; and the time during which it is applied. From the experiments it has been shown, that each of these unfavorable circumstances might easily occasion a loss of from the half of a thirty-second part of a carat, to two thirty-second parts. The writers explain their technical language by observing, that, the whole

mass consisting of twenty-four carats, this thirty-second part denotes $\frac{1}{768}$ th part of the mass. It may easily be conceived, therefore, that if the whole six circumstances were to exist, and be productive of errors falling the same way, the loss would be very considerable.

It is indispensably necessary, therefore, that one uniform process should be followed in the assays of gold; and it is a matter of astonishment, that such an accurate process should not have been prescribed by government for assayers in an operation of such great commercial importance, instead of every one being left to follow his own judgment. The process recommended in the report before us is as follows:—

Twelve grains of the gold intended to be assayed must be mixed with thirty grains of fine silver, and cupelled with 108 grains of lead. The cupellation must be carefully attended to, and all the imperfect buttons rejected. When the cupellation is ended, the button must be reduced by lamination into a plate of one inch and a half, or rather more, in length, and four or five lines in breadth. This must be rolled up upon a quill, and placed in a matrass capable of holding about three ounces of liquid, when filled up to its narrow part. Two ounces and a half of very pure aqua-fortis, of the strength of twenty degrees of Baume's areometer, must then be poured upon it; and the matrass being placed upon hot ashes, or sand, the acid must be kept gently boiling for a quarter of an hour; the acid must then be cautiously decanted, and an additional quantity of one ounce and a half must be poured on the metal, and slightly boiled for twelve minutes. This being likewise carefully decanted, the small spiral piece of metal must be washed with filtered river water, or distilled water, by filling the matrass with this fluid. The vessel is then to be reversed, by applying the extremity of its neck against the bottom of a crucible of fine earth, the internal surface of which is very smooth. The annealing must then be made, after having separated the portion of water which had fallen into the crucible; and, lastly, the annealed gold must be weighed. For the certainty of this operation, two assays must be made in the same manner, together with a third assay upon gold of twenty-four carats, or upon gold the fineness of which is perfectly and generally known.

No conclusion must be drawn from this assay, unless the latter gold should prove to be of the fineness of twenty-four carats exactly, or of its known degree of fineness; for, if there be either loss or surplus, it may be inferred, that the other two assays, having undergone the same operation, must be subject to the same error. The operation being made according to this process, by several assayers, in circumstances of importance, such as those which relate to large fabrications, the fineness of the gold must not be depended on, nor considered as accurately known, unless all the assayers have obtained a uniform result without communication with each other. The authors observe, however, that this identity must be considered as existing to the accuracy of half of the thirty-second part of a carat. For notwithstanding every possible precaution or

uniformity, it very seldom happens that an absolute agreement is obtained between the different assays of one and the same ingot; because the ingot itself may differ in its fineness in different parts of its mass.

The assaying of silver does not differ from that of gold, excepting that the parting operation is not necessary. A certain small portion of the silver is absorbed by the cupel and the more when a larger quantity of lead is used, unless the quantity of lead be excessive; in which case most of it will be scorified before it begins to act upon the silver. Messrs. Hellot, Tillet, and Macquer, from their experiments made by order of the French government, have ascertained, that four parts of lead are requisite for silver of eleven pennyweights twelve grains fine, or containing this weight of pure silver, and twelve grains of alloy, in twelve pennyweights; six parts of lead for silver of eleven pennyweights; eight parts lead for silver of ten pennyweights; ten parts lead for silver of nine pennyweights: and so on in the same progression. The following is the assay table of M. D'Arcet:

Titles of the Silver.	Quantities of copper in the alloy.	Doses of lead necessary, the weight of silver being 1.	Relation between the lead and copper.
Silver at 1000	0	3-10ths.	
950	50	3	70 to 1
900	100	7	60—1
800	200	10	50—1
700	300	12	40—1
600	400	14	35—1
500	500	from 16 to 17	32—1
400	600	16—17	26·66—1
300	700	16—17	22·857—1
200	800	16—17	20—1
100	900	16—17	17·77—1
Pure copper,	1000	16—17	16—1

This table supposes, that the title of the silver to be assayed is known; but when it is not, it may be determined approximately, by exposing in the cupel 0·1 part of this silver with 1 of lead. French gold and silver coin contains 1-10th of copper united to the precious metal. British silver coin consists of 12½ silver and 1 copper; our gold coin contains 11-12ths of gold. The remainder is either copper, or a mixture of silver and copper.

In our plate entitled ASSAYING we give the assay furnace and its instruments, as used at the Royal Mint, and Goldsmith's Hall, London.

Fig. 1. AAAA is a front elevation of the assay furnace; *aa* one of two iron rollers on which the furnace rests; *b* the ash-pit; *cc* the ash-pit dampers, moving in a horizontal direction towards each other, for regulating the draught of the furnace; *d* the door, or opening by which the cupels are introduced into the muffle; *e* a movable tunnel or chimney, by which the draught of the furnace is increased.

BBBB, Fig. 2, is a perpendicular section of fig. 1; *aa* ends of the rollers; *b* the ash-pit; *c* one of the ash-pit dampers; *d* the grate; *e* the

plate upon which the muffle rests, and which is covered with loam nearly one inch thick; *f* a section of the muffle representing the situation of the cupels; *g* the mouth-plate, and upon it are laid pieces of charcoal, which during the process are ignited, and heat the air that is to pass over the surface of the cupels; *h* the interior of the furnace, exhibiting the fuel.

The total height of the furnace is two feet six inches and a half; from the bottom to the grate six inches; the grate, muffle, plate, and bed of loam with which it is covered three inches; from the upper surface of the grate to the commencement of the funnel, *e*, is six inches. The square of the furnace which receives the muffle and fuel is eleven inches and three-quarters by fifteen inches. The external sides of the furnace are made of plates of wrought iron, and are lined with a two-inch fire brick.

Fig. 3 is the muffle, a sort of small oven, made of crucible clay, and open at one end. On the floor of the muffle the cupels are ranged in order, so that by a corresponding board as a register, the position of each may be preserved with reference to their respective contents. At the sides of the muffle are three or four slits to allow of the circulation of the air, which is essential to the process. It is usual to spread over the floor of the muffle a thin layer of sand, or powdered chalk, to prevent the fused oxide of lead which may penetrate the cupel, from cementing it to the bottom of the muffle.

Fig. 4 is the muffle plate on which it rests in the furnace.

Fig. 5 is the door seen at *d* in fig. 1, with *n* its sliding mouth-plate.

Fig. 6 represents the mode of closing the mouth of the furnace with cylinders of charcoal, which being ignited, heat the air, before it arrives at the surface of the metal in the cupels.

Fig. 7 two cupels; they are made of bones calcined and reduced to a moderately fine powder, which is mixed up with water so as to form a paste. The shape is produced by ramming this paste into truncated conical moulds, a cavity is then formed at the upper surface of each by means of a round ended pestle or rammer. The cupel is disengaged from the mould, and suffered to become thoroughly dry in the open air before it can be made use of for an assay. The core of ox horns is considered the best substance for producing the phosphate of lime for cupels. Those commonly employed in the mint are one inch in diameter by seven-eighths in depth.

Fig. 8 the teaser for cleaning the grate.

Fig. 9 a larger teaser, which is introduced at the top of the furnace, for keeping a complete supply of charcoal around the muffle.

Fig. 10 the tongs used for charging the assays into the cupels.

Fig. 11 represents a board of wood used as a register, and is divided into forty-five equal compartments, upon which the assays are placed previous to their being introduced into the furnace. When the operation is performed, the cupels are placed in the furnace in situations corresponding to these assays on the board; by these means all confusion is avoided, and with-

out this regularity, it would be impossible to preserve the accuracy which the delicate operation of the assayer requires.

ASSAY-MASTER, an officer, under certain corporations, entrusted with the care of making true touch, or assay, of gold and silver; and giving a just report of the goodness or badness thereof. Such is the assay-master of the mint in the Tower, called also assayer of the king.

The assay-master of the goldsmith's company is an assistant-warden, called also a touch-warden, appointed to survey, assay, and mark all the silver-work, &c. committed to him. There are also assay-masters, appointed by statute, at York, Exeter, Bristol, Chester, Norwich, Newcastle, and Birmingham, for assaying wrought plate. The assay-master is to retain eight grains of every pound Troy of silver brought to him; four whereof are to be put in the pix, or box of deal, to be re-assayed the next year; and the other four to be allowed him for his waste and spillings. 12 and 13 Will. III. c. 4. 1 Ann. c. 9.

Note. The number of pennyweights set down in the assay-master's report, is to be accounted as per pound, or so much in every pound of twelve ounces Troy. For every twenty pennyweights, or ounce Troy, the silver is found by the assay to be worse than standard, or sterling, sixpence is to be deducted; because every ounce will cost so much to reduce it to standard goodness, or to change it for sterling. In gold, for every carat it is set down to be worse than standard, you are to account that in the ounce Troy it is worse by so many times 3s. 8d. And for every grain it is set down worse, you must account it worse by so many times 11d. in the ounce Troy. And for every half grain, 5½d.; for so much it will cost to make it of standard goodness, &c.

ASSAY-BALANCE, a balance used in the operation of assaying. See **BALANCE**.

ASSAY OF WEIGHTS AND MEASURES, often signifies the trial or examination of common weights and measures by the clerk of a market.

ASSECURE, } Barbarous Lat. *assecu-*
ASSECURANCE, } *rare*, Lat. *securus*, to give
ASSECURATION. } assurance.

Can never mischief end as it begun;
But being once out, must farther out of force?
Think you that any means under the sun
Can assure us to indirect a course?

Daniel. Civil War. bk. iii. p. 473.

But how far then reaches this *assurance*? So far as to exclude all fears, all doubting and hesitation? Neither of these. *Bishop Hall's Sermons.*

ASSECUTION. Lat. *assequor, assecutus*, from *ad* and *sequor*, the act of following up, obtaining.

By the canon law, a person after he has been in full possession of a second benefice, cannot return to his first, because it is immediately void by his *assecution* of a second. *Ayliffe's Parergon.*

ASSELYN (John), a famous Dutch painter, the disciple of *Isaiah Vandevelde*. He distinguished himself in historical pieces, battles, landscapes, with ruins and animals, particularly horses. He travelled into France and Italy; and was much pleased with the manner of *Bamboccia*, which he always followed, except in the

painting landscapes, in which *Claude Lorraine* was his model. Twenty-four of his landscapes have been engraved by *Perelle*, and sold at high prices. He died at Amsterdam in 1660.

ASSEMANI, I. S. and S. E. two learned librarians of the Vatican, in the seventeenth and eighteenth centuries. *Joseph Simon* was born at Rome 1687, and died 1768. He wrote *Bibliotheca Orientalis Clementino Vaticana*, Romæ, 1719-28, 4 vols. folio, affording ample proof of his learning in the numerous notices it contains of Syriac, Arabic, and Persian manuscripts, with lives of their authors. S. Ephræm, Syri, Opera omnia, quæ extant, Græcæ, Syriacæ, et Latine, Romæ, 1732-34, 6 vols. folio; *Italicæ Historiæ Scriptores ex Bibl. Vat.*, Romæ, 1751-53, 4 vols. 4to; *Kalendaria Ecclesiæ Universæ*, &c. Romæ, 1755-57, 6 vols. 4to. *Assemani*, S. E. nephew of the foregoing, wrote *Bibliothecæ Medicæ Laurentinæ et Palatinæ Codd. MSS. Orientalium Catalogus*, Florentiæ, 1742, 2 vols. folio; *Acta Sanctorum Martyrum Oriental et Occidental*, Romæ, 1748, 2 vols. folio.

ASSEMBLANCE. Fr. *sembler*, a likeness. See **SEMBLANCE**.

FALST. Will you tell me, Master Shallow, how to chuse a man? Care I for the limbe, the thewes, the stature, bulke, and bigge *assemblance* of a man? Give me the spirit, Master Shallow.

Shakspeare. Henry IV. part ii.

ASSEMBLE, *v. & n.* } Fr. *assembler*, from
ASSEMBLAGE, } the Latin *ad*, to, and
ASSEMBLANCE, } *simul*, together. To
ASSEMBLER, } bring together, or in
ASSEMBLING, } one place; to collect;
ASSEMBLY. } to convene.

A rout of people there *assembled* were,
Of every sort and nation under sky,
Which, with great uproar, pressed to draw near
To the upper part, where was advanced high
A stately seat of sovereign majesty. *Spenser.*

Mahomet made the people believe that he would call a hill to him; and from the top of it offer up his prayers for the observers of his law. The people *assembled*; Mahomet called the hill to come to him, again and again; and, when the hill stood still, he was never a whit abashed, but said; 'If the hill will not come to Mahomet, Mahomet will go to the hill.'

Lord Bacon's Essays.

These men *assembled*, and found Daniel praying. *Daniel.*

And he shall set up an ensign for the nations, and shall *assemble* the outcasts of Israel, and gather together the dispersed of Judah. *Isaiah xi. 12.*

He wonders for what end you have *assembled*
Such troops of citizens to come to him.

Shakspeare.

Assemble all in choirs, and with their notes
Salute and welcome up the rising sun. *Otway.*

O Hartford (fitted, or to shine in courts
With unaffected grace, or walk the plains,
With innocence and meditation join'd
In soft *assemblage*) listen to my song! *Thomson.*

The ASSEMBLY OF DIVINES at Westminster, was an association of ministers and others, summoned by ordinance of parliament, in the year 1643, to meet at Westminster, 'for settling the government and liturgy of the church of England, and for vindicating and clearing the said church from false aspersions and interpretations.'

It also met expressly according to the words of the covenant, 'for the extirpation of prelacie, that is church-government by arch-bishops, bishops, their chancellors, and commissaries, deans and chapters, archdeacons and all other ecclesiastical officers.' This assembly consisted of 121 divines and thirty laymen, 'celebrated 'in their party,' says Mr. Hume, 'for piety and learning.' The leading parties were the Presbyterians, Erastians, and Independents. The works of the assembly, besides some letters to foreign churches, and occasional admonitions were, 1. Their humble Advice to Parliament, for Ordination of Ministers, and settling the Presbyterian Government. 2. A Directory for Public Worship. 3. A Confession of Faith. 4. A larger and a shorter Catechism. 5. A Review of some of the Thirty-nine Articles. Both the larger and shorter Assembly's catechism, are largely in use at the present time among the English Calvinistic dissenters.

ASSEMBLIES of the clergy are otherwise called convocations, synods, councils. The annual meeting of the church of Scotland is called the General Assembly; in which his Majesty is represented by his commissioner, generally a Scottish nobleman, but who has no voice in the deliberations: his duty being confined to the calling and dissolution of the meeting, which he does in the name of his Majesty, whilst the Moderator does the same in the name of the Lord Jesus Christ. This assembly possesses the highest authority in the church of Scotland; a presbytery, composed of fewer than twelve parishes, sends two ministers and one ruling elder to the assembly; if it contains between twelve and eighteen ministers, it sends three of these, and one ruling elder; if it contains between eighteen and twenty-four ministers, it sends four ministers and two ruling elders; and of twenty-four ministers, it sends five with two ruling elders. Every royal borough deposes one ruling elder, and Edinburgh two; their election must be attested by the kirk-session of their respective boroughs. Every university sends one commissioner from its own body. The commissioners are chosen annually six weeks before the meeting of the assembly; and the ruling elders are often men of the first eminence for rank and talents.

ASSEMBLIES of the Roman people were called comita.

ASSEMBLIES OF THE STATES. Under the Gothic governments, the supreme legislative power was lodged in an assembly of the states of the kingdom held annually for the like purposes as our parliaments. There were some feeble remains of them in France and Poland before the late revolutions and counter-revolutions.

ASSEMBLY, in the military art, the second beating of a drum before a march; at which the soldiers strike their tents, roll them up, and stand to arms. See DRUM.

ASSENS, a bailiwick and town of Denmark, on the west coast of the island of Funen, which carries on a considerable trade in corn. It is also called Asnes, which signifies the holy promontory. A battle was fought in it, in 1536, wherein Christian III. obtained a decisive victory

over Christian II. Here is a ferry across the little Belt to Holstein. Long. 9° 54' E., lat. 55° 20' N.

ASSENT, *v. & n.* } Lat. *assentior*, from *ad*,
ASSENTA'TION, } and *sentio*, to think to,
ASSENTA'TOR, } be of the same opinion.
ASSENT'ER, } To agree to what is pro-
ASSENT'MENT. } posed, to bring one's
mind to a thing, to comply. Assentation is synonymous with flattery; obsequiousness.

And the Jews also *assented*, saying that these things were so. Acts xxiv. 9.

Their arguments are but precarious, and subsist upon the charity of our *assentments*.

Brown's Vulgar Errors.

To urge any thing upon the church; requiring thereunto that religious *assent* of Christian belief, wherewith the words of the holy prophets are received, and not to show it in scripture; this did the Fathers evermore think unlawful, impious, and execrable. Hooker.

The evidence of God's own testimony, added unto the natural *assent* of reason concerning the certainty of them, doth not a little comfort and confirm the same. Id.

Without the king's *assent* or knowledge,

You wrought to be a legate. Shakspeare

Faith is the *assent* to any proposition, not thus made out by the deduction of reason, but upon the credit of the proposer. Locke.

All the arguments on both sides must be laid in balance; and, upon the whole, the understanding determine its *assent*. Id.

Man is the world's high-priest, he doth present
The sacrifice for all, while they below,
Unto the service mutter an *assent*,
Such as springs use, that fall, and winds that blow.

Herbert.

One would think that hell should have little need of the fawning *assentation* of others, when men carry so dangerous parasites in their own bosoms; but sure, both together must needs help to people that region of darkness. Bishop Hall's *Soliloquies*.

He ceased; th' assembled warriors all *assent*,

All but Atrides. Cumberland.

Precept gains only the cold approbation of reason, and compels an *assent* which judgment frequently yields with reluctance, even when delay is impossible.

Haynesworth.

The ROYAL ASSENT is the approbation given by the king in parliament, to a bill which has passed both houses, after which it becomes a law.

The royal assent may be given in two ways. 1. In person; when the king comes to the house of peers, in his crown and royal robes, and sending for the commons to the bar, the titles of all the bills that have passed both houses are read; and the king's answer is declared by the clerk of the parliament in Norman-French. If the king consents to a public bill, the clerk usually declares, 'le roy le veut; the king wills it so to be;' if to a private bill, 'soit fait comme il est desiré; be it as it is desired.' If the king refuses his assent, it is in the gentle language of 'le roy s'avisera; the king will advise upon it.' When a money-bill, or bill of supply, is passed, it is carried up and presented to the king by the speaker of the house of commons; and the royal assent is thus expressed 'le roy remercie ses loyal sujets, accepte leur benevolence, et aussi le veut;

the king thanks his loyal subjects, accepts their benevolence, and wills it so to be.'

In case of an act of grace, which originally proceeds from the crown, and has the royal assent in the first stage of it, the clerk of the parliament thus pronounces the gratitude of the subject; 'les prelats, seigneurs, et communs, en ce present parlement assembleés, au nom de tous vous autres sujets, remercient tres humblement votre majeste, et prient a Dieu vous donner en sante bone vie et longue; the prelates, lords, and commons, in this present parliament assembled, in the name of all your other subjects, most humbly thank your majesty, and pray to God to grant you health and wealth long to live.'

2. By the statute 33 Hen. VIII. c. 21., the king may give his assent, by letters patent, under his great seal, signed with his hand, and notified in his absence to both houses, assembled together in the high house. And when the bill has received the royal assent in either of these ways it is then, and not before, a statute or act of parliament: a copy of which is usually printed at the king's press, for the information of the whole land. See Blackst. Com. book i. chap. 2.

ASSER, or ASER, a Jewish rabbi of the fifth century, who, with other learned rabbins, compiled the collection of Hebrew traditions called the Babylonian Talmud. This was printed at Leyden, 1630, in 4to.; but the most complete edition is one published in 1744, at Amsterdam, twelve volumes folio, with an ample commentary. Asser died in 427, aged seventy-four.

ASSER (John), or ASSERIUS MENEVENSIENSIS, (i. e. Asser of St. David's), bishop of Sherborne in the reign of Alfred the Great. He was born in Pembroke-shire, South Wales; and educated in the monastery of St. David's. By his assiduous application he soon acquired universal fame as a person of profound learning and great abilities. Alfred the munificent patron of genius, about the year 880, sent for him to his court, then held at Dean in Wiltshire. He was so charmed with Asser, that he made him his preceptor and companion: appointed him abbot of two or three different monasteries; and at last promoted him to the see of Sherborne, where he died in 910. He is said to have been principally instrumental in persuading the king to restore the university of Oxford to its pristine dignity; and wrote *De Vita et Rebus Gestis Alfredi*, &c. Lond. 1574, published by archbishop Parker, in the old Saxon character, at the end of Walsinghami Hist.—Francf. 1602, 6s. Oxf. 1722, 8vo. Many other works are ascribed to this author by Gale, Bale, &c. but on very doubtful authority.

ASSERIA, ASS-ESTIA, or AS-ESTIA, an ancient town of Laburnia, now in ruins. Pliny, having specified the Laburnian cities that were obliged to attend the congress of Scardonia, adds to the catalogue the free Asserians, immunesque Asserriates; a people who created their own magistrates, and were governed by their own municipal laws.

ASSERIDA, in botany, a name given by the people of Guinea to a kind of shrub, the leaves of which being chewed, are a cure for the colic.

ASSERT'Y,
ASSERTA'CION,
ASSERT'ION,
ASSERT'IVE,
ASSERT'IVELY,
ASSERT'OR,
ASSERT'ORY.

Assero, assertum, to kri to, to sew to. To abide by, to bear the consequence of an opinion, to hold, to maintain, to affirm.

That tongue

Inspir'd with contradiction, durst oppose
A third part of the gods, in synod met,
Their deities to assert.

Milton.

Among th' asserters of free reason's claim,
Our nation's not the least, in worth or fame,
The world to Bacon does not only owe
It's present knowledge, and its future too.

Dryden's Epistles.

Faithful assertor of thy country's cause,
Britain with tears shall bathe thy glorious wound.

Prior.

It is an usual piece of art to undermine the authority of fundamental truths, by pretending to shew how weak the proofs are which their assertors employ in defence of them.

Atterbury.

He was not so fond of the principles he undertook to illustrate, as to boast their certainty; proposing them, not in a confident and assertive form, but as probabilities and hypotheses.

Glanville.

The Epicureans contented themselves with the denial of a Providence, asserting at the same time the existence of gods in general, because they would not shock the common belief of mankind.

Adisson.

We, as it were, lean forward with surprise and trembling, to behold the human soul collecting its strength, and asserting a right to superior fates.

Usher.

When the great soul buoys up to this high point,
Leaving gross nature's sediments below,
Then, and then only, Adam's offspring quits
The sage and hero of the fields and woods,
Asserts his rank and rises into man.

Young.

It is an erect countenance; it is a firm adherence to principle; it is a power of resisting false shame and frivolous fear, that assert our good faith and honour, and assure us of the confidence of mankind.

Burke.

Sophocles also, in a fragment of one of his tragedies, asserts the unity of the supreme being.

Cumberland.

But, lo! from high Hymettus to the plain,
The queen of night asserts her silent reign.

Lord Byron's Corsair.

ASSESS', v. & n. } Ital. *assessare*, to set to,
ASSESS'IONARY, } impose a tax. Legally
ASSESS'MENT, } done by a sitting or council, and agreement of those
ASSESS'OR. } authorised to impose it. Assessor is a legal adviser to a magistrate, sitting by him on the bench.

To his Son,

Th' assessor of his throne, he thus began.

Milton.

Twice stronger than his sire, who sat above,
Assessor to the throne of thund'ring Jove.

Dryden.

Minos, the strict inquisitor, appears;
And lives and crimes, with his assessors, hears:
Round, in his urn, the blended balls he rolls;
Absolves the just, and dooms the guilty souls.

Id.

What greater immunity and happiness can there be to a people, than to be liable to no laws, but what they make themselves? To be subject to no contribution, assessment, or any pecuniary levy whatsoever, but what they vote, and voluntarily yield unto themselves.

Howell.

One of the answers of the jury, upon their oaths, at the *assessionary* court, I have inserted.

Carew's Survey of Cornwall.

Pausanias sat the judge;

Callicrates and Aemnestus wise,

His two *assessors*. *Glover's Athenaid.*

ASSETS, in law, are either real or personal. Where a man hath lands in fee simple, and dies seized thereof, the lands which come to his heir are assets real; and where he dies possessed of any personal estate, the goods which come to the executors are assets personal. Assets are also divided into assets per descent, and assets inter males.

1. **ASSETS BY DESCENT** are where a person is bound in an obligation, and dies seized of lands which descend to the heir, the land shall be assets, and the heir shall be charged as far as the land to him descended will extend.

2. **ASSETS INTER MAINES** are when a man indebted makes executors, and leaves them sufficient to pay his debts and legacies; or where some commodity or profit ariseth to them in right of the testator, which are called assets in their hands. This term is also applied commercially to any available property for the payment of a man's debts.

ASSEVERER, } Lat. *assevero*; *ad*, and *se-*
ASSEVERATION. } *verus*. To say or affirm severely or solemnly; to assure; to maintain seriously.

GUISE. You must, you will, and smile upon my murder.

MARMONTIER. Therefore, if you are conscious of a breach,

Confess it to me: lead me to the king,
He has promis'd me to conquer his revenge,
And place you next him; therefore, if you're right,
Make me not fear it by *asseverations*,
But speak your heart, and O resolve me truly.

Dryden. Duke of Guise.

'I will come and some of you shall see me coming.' Can it be supposed that in such an *asseveration*, the word to 'come' may bear two different senses.

Horsley's Sermons.

ASSIDEANS, or **CHASIDÆANS**; from the Heb. חסידים, *chasideim*, merciful, pious; those Jews who resorted to Mattathias to fight for the law of God and the liberties of their country. They were men of great valor and zeal, having voluntarily devoted themselves to a more strict observation of the law than other men. For after the return of the Jews from the Babylonish captivity, there were two sorts of men in their church; those who contented themselves with that obedience only which was prescribed by the law of Moses, and who were called *Zadikim*, i. e. the righteous; and those who, over and above the law, superadded the constitutions and traditions of the elders, and other rigorous observances: these latter were called *Chasideim*, i. e. the pious. From the former sprung the Samaritans, Sadducees, and Caraites; from the latter, the Pharisees and the Essenes.

ASSIDENT SIGNS, in medicine, are symptoms which usually attend a disease but not always; hence differing from pathognomic signs, which are inseparable from the disease: e. g. in the pleurisy, a pungent pain in the side; in an acute fever, difficulty of breathing, &c collectively

taken, are pathognomic signs; but that the pain extends to the hypochondrium or clavicle, or that the patient lies with more ease on one side than on the other, are assident signs.

ASSID'UATE, } Lat. *assideo*, to sit down
ASSID'UITY, } at any thing constantly or
ASSID'UOUS, } daily. Constant in appli-
ASSID'UOUSLY. } cation, unwearied, diligent, sedulous.

And if by pray'r
Incessant I could hope to change the will
Of him who all things can, I would not cease
To weary him with my *assiduous* cries. *Milton.*
The most *assiduous* tale-bearers; and bitterest revilers, are often half-witted people.

Government of the Tongue.

In summer, you see the hen giving herself greater freedoms, and quitting her care for above two hours together; but in winter, when the rigour of the season would chill the principles of life, and destroy the young one, she grows more *assiduous* in her attendance, and stays away but half the time.

Addison.

Each still renews her little labour,
Nor justles her *assiduous* neighbour. *Prior.*
We observe the address and *assiduity* they will use to corrupt us. *Rogers.*

The habitable earth may have been perpetually the drier, seeing it is *assiduously* drained and exhausted by the seas. *Bentley.*

A scholar is industrious, who doth *assiduously* bend his mind to study for getting knowledge.

Barrow's Sermons.

Often as she mounts
Or quits the car, his arm her weight sustains
With trembling pleasure. His *assiduous* hand
From purest fountains wafts the living food.

Glover. Leonidas, book viii. p. 57.

ASSIDUI, in Roman antiquity, volunteers who served in the army at their own expense.

ASSIDUUS, or **ADSIDUUS**, from *as*, money, among the Romans, denoted a rich or wealthy person. Hence we meet with *assiduous* sureties, *assidui fide-jussores*. When *Servius Tullius* divided the Roman people into five classes, according as they were assessed, the richer sort who contributed *asses* were denominated *assidui*; and as these were the chief people of business who attended all the public concerns, those who were diligent in attendances came to be denominated *assidui*.

ASSIEGE'. Fr. *assiéger*, to sit down before. To sit down before a town, to besiege.

Swiche wondring was ther on this hors of brass,
That sin the gret *ussege* of Troye was,
Ther as men wondred on an hors also,
Ne was ther swiche a wondring, as was tho.

Chaucer. The Squier's Tale, vol. i. p. 431.

On th' other side th' *assieged* castles ward
Their stedfast arms did mightily maintain.

Spenser.

I leave what glory virtue did attain,
At th'ever memorable Agincourt.

I leave to tell, what wit, what pow'r did gain
The *assieg'd* Roan, Caen, Dreux; or in what sort.

Daniel. Civil War, book v.

ASSIENTO, Span. a contract. The first of this kind was made by the French Guinea Company; and, by the treaty of Utrecht, transferred to the English, who were to furnish 4800 negroes to Spanish America annually.

ASSIGN', *v. & n.* } Lat. *assigno*; *ad*, and
 ASSIGN'ABLE, } *signo*, to mark or sign.
 ASSIGNA'TION, } To mark off, to appoint,
 ASSIGN'EE', } to set apart, to appropriate
 ASSIGN'ER, } to a particular use, to
 ASSIGN'MENT. } allot, to bring forward as

a cause of reason.

At last, as forced by false Ulysses crye,
 Of purpose he brake fourth, *assigning* me
 To the altar. *Surrey.*
 He *assigned* Uriah unto a place where he knew that
 valiant men were. 2 Sam. xi. 16.

The two armies were *assigned* to the leading of two
 generals, both of them rather courtiers assured to the
 state, than martial men. *Bacon.*

The only thing which maketh any place publick,
 is the publick *assignment* thereof unto such duties.

Hooker.

Thus most invectively he (Jaques) pierceeth through
 The body of the country, city, court,
 Yea, and of this our life, swearing that we
 Are mere usurpers, tyrants, and what's worse
 To fright the animals, and to kill them up
 In their *assigned* and native dwelling-place.

Shakspeare. As You Like It.

The cause of love can never be *assigned*,
 'Tis in no face, but in the lover's mind.

Dryden. Tyrannic Love.

Both joining,

As join'd in injuries, one enmity
 Against a foe by doom express *assign'd* us,
 That cruel serpent. *Milton.*

This institution, which *assigns* it to a person whom
 we have no rule to know, is just as good as an *assign-
 ment* to nobody at all. *Locke.*

The lovers expected the return of this stated hour
 with as much impatience as if it had been a real *as-
 signation*. *Spectator.*

True quality is neglected, virtue is oppress'd, and
 vice triumphant. The last day will *assign* to every
 one a station suitable to the dignity of his character.

Addison.

The opel is at once the *assigner* of our tasks, and
 the magazine of our strength. *Decay of Piety.*

ASSIGN, or ASSIGNEE, in common law, a person
 to whom a thing is assigned or made over. The
 word *assign* is said to have been introduced in
 favor of natural children; who, because they can-
 not pass by the name of heirs, are included under
 that of assigns. For Assignee, in bankruptcy,
 see BANKRUPTCY.

ASSIGNABLE MAGNITUDE, in geometry, any
 finite magnitude.

ASSIGNABLE RATIO, the ratio of finite quanti-
 ties.

ASSIGNATS, a species of paper currency,
 issued by the government of France, for sums of
 different values, to the amount of many thousand
 millions of livres, to support the credit of the re-
 public during the course of the revolution.

ASSIGNMENT, may be more accurately de-
 fined, the act of transferring the interest or pro-
 perty a man has in any thing; or of appointing
 or setting over a right to another.

ASSIGNMENT of a Dowry, is the setting
 out of a woman's portion by the heir.

ASSIMILATE, } Lat. *assimilo*, *assimila-*
 ASSIMILATION, } *to*; from *ad*, and *similis*,
 ASSIMILATIVE, } to bring to the like, to
 ASSIMILATE, } make like, to liken, to
 ASSIMILATE, } resemble, to convert to its
 own substance by digestion, and the process car-
 ried on in animal or vegetable bodies.

The spirits of many will find but naked habita-
 tions; meeting no *assimilables* wherein to re-act their
 natures. *Brown's Vulgar Errors.*

How little must the ordinary occupations of men
 seem to one who is engaged in so noble a pursuit as
 the *assimilation* of himself to the Deity. *Berkeley.*

Fast falls a fleecy show'r: the downy flakes

Descending, and with never ceasing lapse

Softly alighting upon all below,

Assimilate all objects. *Cowper's Poems.*

A ruin is a sacred thing. Rooted for ages in the
 soil, *assimilated* to it, and become as it were a part of
 it, we consider it a work of nature, rather than of art.

Gilpin's Tour to the Lakes.

ASSIMILATION, in physics, is that motion
 by which bodies convert other bodies related to
 them, or at least such as are prepared to be con-
 verted, into their own substance and nature.
 Thus flame multiplies itself upon oily bodies,
 and generates new flame; air upon water, and
 produces new air; and all the parts, as well
 similar as organical, in vegetables and animals,
 first attract with some election or choice, nearly
 the same, common or not very different juices for
 aliment, and afterwards *assimilate* or convert them
 to their own nature.

ASSINIBONS, a native tribe of North Ameri-
 cans, whose name has been given to the western
 branch of the Great Red River. This stream
 divides itself into two branches, about thirty
 miles from its estuary in lake Winnipeg, the
 eastern branch bearing the name of the Red
 River from its source, the western, which rises
 in N. lat. 51° 15', and W. long. 103° 20', that
 of Assinibons. Extensive plains, covered with
 a short rank grass, and crowded with buffaloes
 and elks, extend between these streams, but tim-
 ber even for firewood is scarce. The soil is
 gravelly, and beds of lime and stone form the
 rapids of these rivers; which are both navigable
 by canoes up to their source.

ASSINT, a parish of Scotland in the county
 of Sutherland, about fifteen miles in breadth,
 and twenty-five in length.

ASSIRATUM, in antiquity, a bloody draught,
 wherewith treaties were ratified. It was made of
 wine and blood, called by the ancient Romans
assir.

ASSIS, in physiology, opium, or a powder
 made of hemp-seed, which being formed into
 boluses about the bigness of chestnuts, is swal-
 lowed by the Egyptians, who hereby become
 intoxicated and ecstastic. It is called by the
 Turks *asserac*.

ASSISA CADERE, in law; from *assideo*, to be
 nonsuited; when the complainant, from defect of
 legal evidence can proceed no further. *Assisa*
cadit in juratum, is where a thing in controversy
 is so doubtful that it must necessarily be tried by
 a jury. *Assisa continuanda*, a writ directed to
 justices of assize for the continuation of a cause
 when certain records alleged cannot be produced
 in time by the party that has occasion to use them.
Assisa proroganda, a writ for the stay of proceed-
 ings by reason of the parties being employed in
 the king's business. *Assisa panis et cerevisiæ*,
assize of bread and beer, a statute for regulat-
 ing their weight and quantity. *Assisa No-*
cuamenti, see NUISANCE. *Assisa capi in mo-*
duum assize, when the defendant pleads di-
 rectly to the *assize*.—*Assisa judicum*, a judg-

ment of the court given either against the plaintiff or the defendant.

ASSISI, a small town in the papal dominions, in the duchy of Spoleto: the see of a bishop. St. Francis, the celebrated founder of the Franciscan order, was born here; and lies buried in the Sacro Convento. Near the foot of the hill on which the town stands is a rustic chapel, dedicated to the virgin and the angels, in which St. Francis is supposed to have received his first call to devotion. Over this a spacious church has been erected; and, on the second of August, multitudes of pilgrims flock to it from the adjoining provinces. When Mr. Eustace passed it in 1802, one of the fathers informed him, that more than 10,000 persons had attended the last anniversary, and that ten had been suffocated or trampled to death, in pressing forward to touch the altar. Here are the ruins of a temple of Minerva, built about the time of Augustus. The portico consisted of six fluted Corinthian columns, each having a distinct pedestal. It is now used as the portico of the church of Santa Maria di Minerva. In the neighbourhood of Assisi are other vestiges of Roman magnificence; ruins of baths, temples, and an aqueduct. The bishopric was dissolved by the French in 1810. Twenty miles N.N.W. of Spoleto. Long. 12° 30' E., lat. 43° 3' N.

ASSISI, in ecclesiastical writers, persons benefited in a cathedral church, not in a rank below that of canons; thus called, either because they were allowed an assisia or pension, or from assiduus, diligent.

ASSIST, ASSIST'ANCE, ASSIST'ANT, ASSIST'LESS, } *Assisto*; from *ad*, and *sisto*, to stop or stay. To place one's self by another so as to give him our strength; to stand by, not in the sense of to look on, but to give support—to help.

The council of Trent commends recourse, not only to the prayers of the saints, but to their aid and assistance: what doth this aid and assistance signify?

Stillingfleet.
You have abundant assistances for this knowledge, in excellent books. *Wake's Prep. for Death.*

One bull, with curl'd black head beyond the rest,
And dew-laps hanging from his brawny chest,
With nodding front awhile did daring stand,
And with his jetty hoof spurn'd back the sand:
Then, leaping forth, he bellow'd out aloud:
Th' amazed assistants back each other crowd,
While monarch-like he rang'd the listed field;
Some toss'd, some gor'd, some trampling down, he kill'd. *Dryden. Conquest of Granada, part i.*

Let us entreat this necessary assistance, that by his grace he would lead us. *Rogers.*

Loose at each joint; each nerve with horror shakes,
Stupid he stares, and all assistless stands.
Such is the force of more than mortal hands.

Pope. Homer's Iliad, book xvi.
God assists us in the virtuous conflict, and will crown the conqueror with eternal rewards. *Blair.*

While my thoughts were thus employed, I was sent by Metophis towards the mountains of the desert Oasis, that I might assist his slaves in looking after his flocks, which were almost without number.

Hawkesworth's Telemachus.
Eternal God,

Guide thou my footsteps in the way of truth,
And oh! assist me so to live on earth,
That I may die in peace, and claim a place
In thy high dwelling. *Kirke White's Poem.*

ASSISTANTS, in various trading or public companies, members who have the whole power of managing the company's affairs; and commonly called the court of assistants.

ASSISUS, in ancient law writers, a thing farmed out for a certain rent, in money or provisions.

ASSITHMENT; from *ad*, to, Lat. and *sithe*, Sax. instead of; a weregild, or compensation by a pecuniary mulct, quod vita supplicii ad expiandum delictum solvitur.

ASSIZE', *v. & n.* Fr. *assis*, part. past, from the verb *asseoir*, to sit. To sit judicially, or under the sanction or appointment of the law.

There nas not a point truely
That it nas in his right assise.

Chaucer. The Romaunt of the Rose, ch. i.

When in mid air the golden trump shall sound,
To raise the nations under ground;

When in the valley of Jehosaphat

The judging God shall close the book of fate;

And there the last assizes keep,

For those who wake, and those who sleep.

Dryden. Ode to the Memory of Mrs. A. Killigrew.

ASSIZE, in old English law books, is defined to be an assembly of knights, and other substantial men, together with a justice, in a certain place, and at a certain time; but the word, in its present acceptation, implies a court, place, or time, when and where the writs and processes, whether civil or criminal, are decided by judge and jury. All the counties of England were, very anciently, divided into six circuits, and two judges assigned by the king's commission, to hold their assizes twice a-year in every county, except London and Middlesex. They were afterwards directed by magna charta, c. 12. to be sent into every county once a-year to take or try certain actions then called recognitions or assizes; the most difficult of which they are directed to adjourn into the court of common pleas to be there determined. But the present justices of assize and nisi prius are more immediately derived from the statute Westm. 2. 13 Edw. I. c. 30. explained by several other acts, particularly the statute 14 Edw. III. c. 16. and must be two of the king's justices of the one bench or the other, or the chief baron of the exchequer, or the king's sergeants sworn. They usually make their circuits in the respective vacations after Hilary and Trinity terms; assizes being allowed to be taken in the holy time of Lent by consent of the bishops at the king's request, as expressed in statute Westm. 1. 3 Edw. I. c. 51. The judges upon the circuits now sit by virtue of five several authorities. 1. The commission of the peace in every county of the circuits; and all justices of the peace of the county are bound to be present at the assizes; and sheriffs are also to give their attendance on the judges, or they shall be fined. 2. A commission of oyer and terminer, directed to them and many other gentlemen of the county, by which they are empowered to try treasons, felonies, &c and this is the largest commission they have. 3. A commission of general gaol-delivery, directed to the judges and the clerk of assize associate, which gives them power to try every prisoner in the gaol committed for any offence whatsoever, but none except

prisoners in the gaol: so that one way or other they rid the gaol of all the prisoners in it. 4. A commission of assize, directed to the judges and clerk of assize, to take assizes; that is to take the verdict of a peculiar species of jury called an assize, and summoned for the trial of landed disputes: the other authority is, 5. That of *nisi prius*, which is a consequence of the commission of assize, being annexed to the office of those justices by the statute of Westm. 2. 13 Edw. I. c. 30. And it empowers them to try all questions of fact issuing out of the courts of Westminster, that are then ripe for trial by jury. Formerly, the judges could not act in counties where they resided or were born; but this custom is abrogated by 49 Geo. 3. c. 91.

ASSIZE, or jury, in Scots law, consists of fifteen sworn men, (juratores,) picked out by the court from a greater number, not exceeding forty-five, who have been summoned for that purpose by the sheriff, and given in a list to the defender, at serving him with a copy of his libel.

ASSIZER, or ASSISER, from assize; an officer that has the care and oversight of weights and measures in various parts of England.

ASSOCIATE, *v. n. & adj.* } Lat. *adsocio*,
ASSOCIATION, } from *ad*, and *so-*
ASSOCIATOR. } *cio*, from *sequor*,
to follow. To meet together as equals, to keep in company, to be partners, confederates.

Their defender, and his *associates*, have sithence proposed to the world a form, such as themselves like.

Hooker.

The church, being a society, hath the self-same original grounds which other politic societies have; the natural inclination which all men have unto sociable life, and consent to some certain bond of *association*; which bond is the law that appointeth what kind of order they should be *associated* in. *Id.*

A fearful army, led by Caius Marcius,
Associated with Aufidius, rages

Upon our territories.

Shakespeare.

Sole Eve, *associate* sole, to me (beyond
Compare) above all living creatures dear.

Milton.

Associate in your town a wand'ring train;

And strangers in your palace entertain.

Dryden.

He was accompanied with a noble gentleman, no
unsuitable *associate*.

Wotton.

They persuade the king, now in old age, to make
Plangus his *associate* in government with him.

Sidney.

Self-denial is a kind of holy *association* with God;
and, by making you his partner, interests you in all
his happiness.

Boyle.

Association of ideas is of great importance, and may
be of excellent use.

Watts.

But my *associates* now my stay deplore,

Impatient.

Pope. Odyssey.

ASSOCIATE PRESBYTERY, the title first assumed
by those clergymen who associated together,
after seceding from the church of Scotland, in
1733.

ASSOCIATE SYNOD, was the highest ecclesiastical
court among the Antiburgher Seceders of
Scotland. Its decisions being final, like those of
the General Assembly. See Antiburgher and
Seceders.

ASSOCIATION, in law, is a patent by the king,
either of his own motion, or at the suit of
a party plaintiff, to the justices of assize; to

have other persons *associated* with them, in
order to take the assize.

ASSOCIATION OF IDEAS, is where two or more
ideas constantly and immediately accompany
or succeed one another in the mind, so that
one shall almost infallibly produce the other,
whether there be any natural relation between
them or not. See METAPHYSICS. Wrong com-
binations of ideas, Mr. Locke shows, are a great
cause of the irreconcilable opposition between
different sects of philosophy and religion: for
we cannot imagine, that all who hold tenets dif-
ferent from, and sometimes even contradictory
to one another, should wilfully and knowingly
impose upon themselves, or refuse truth offered
by plain reason: but some loose and independ-
ent ideas are by education, custom, and the
constant din of party, so coupled in their minds,
that they always appear there together: these
they can no more separate in their thoughts,
than if they were but one idea; and they operate
as if they were so. This gives the appearance
of sense to jargon, of demonstration to absurdities,
and of consistency to nonsense. It is the
foundation of the greatest, and almost of all the
errors in the world. Association forms a prin-
cipal part of Dr. Hartley's mechanical theory of
the mind. He distinguishes it into synchronous
and successive; and ascribes our simple and
complex ideas to the influence of this principle
or habit. Particular sensations result from pre-
vious vibrations conveyed through the nerves to
the medullary substance of the brain; and these
are so intimately associated together, that any
one of them, when impressed alone, shall be
able to excite in the mind the ideas of all the
rest. Thus we derive the ideas of natural
bodies from the association of the several sen-
sible qualities with the names that express them,
and with each other. The sight of part of a
large building suggests the idea of the rest in-
stantaneously, by a synchronous association of
the parts; and the sound of the words, which
begin a similar sentence, brings to remembrance
the remaining parts, in order, by successive as-
sociation. Dr. Hartley maintains, that simple
ideas run into complex ones by association;
and apprehends, that, by pursuing and perfecting
this doctrine, we may some time or other be
enabled to analyse those complex ideas, that are
commonly called the ideas of reflection, or intel-
lectual ideas, into their several component parts,
i. e. into the simple ideas of sensation of which
they consist; and that this may be of con-
siderable use in the art of logic, and in ex-
plaining the various phenomena of the human
mind.

ASSODES, in medicine, a continued fever,
wherein the surface is moderately warm, but the
internal heat great.

ASSOIL, } Supposed to be from the
ASSOILMENT. } Fr. *absoudre*; Lat. *absolvere*,
to loose or free from. To absolve from guilt; to
liberate from punishment; to pardon, to forgive.

This is my drede, and ye, my brethren tweic,
Assolleth me this question I prie.

Chaucer. The Marchantes Tale.

But secretly *assailing* of his sin,
No other med'cine will unto him lay.

Mirror for Manistrates

I also will aske of you a certayne questio., whiche yf ye *assoyle* me, I in lykewyse will tell you by what auctorite. In these thynges.

Bible, 1551. *Matthew* ch. xxi.

But with such guilefull appendices of oathes imposed on him, that this *assoilement* was not so much the epilogue of his olde, as the prologue of his new tragical vexations.

Speed's History of Great Britaine.

To *ASSOILE*, in our ancient law books, signifies to absolve from an excommunication.

ASSONANCE, in rhetoric and poetry, a term used where the words of a phrase or verse have the same sound or termination, and yet make no proper rhyme. These are usually accounted vicious in English; though the Romans sometimes used them with elegance: as, *Militem comparavit, exercitum ordinavit, aciem lustravit.*

ASSORT, } Fr. *assortir*, from the Lat.
ASSORTMENT. } *sors*, lot. To sort, to put things of the same kind or class together, to match, to suit.

Ye ne be but fools of good disport!

I wole you teachen a new play;

Sit down here by one *assort*,

And better mirth never ye seigh.

Sir Ferumbas, in *Ellis*, v. ii. p. 401.

A taylor sat musically at it in a shed over against the convent, in *assorting* four dozen of bells for the harness, whistling to each bell as he tied it on with a thong.

Sterne's Tristram Shandy.

An adjective is by nature a general, and in some measure an abstract word, and necessarily presupposes the idea of a certain species or assortment of things, to all of which it is equally applicable.

Smith's Moral Sentiments.

ASSOS, a sea-port of Natolia, subject to the Turks, on a bay of the Ægean Sea, twelve miles south-east of Troas.

ASSRUMINA, in botany, the name given by the people of Guinea to the shrub whose leaves they use as a cure for long worms, which are found in their flesh: they bruise the leaves, and apply a large lump of the mass to the part.

ASSUAGE, } Old Fr. *assouager*. The
ASSUAGEMENT, } modern Fr. is *soulager*. To
ASSUASIVE. } soften, to alleviate pain or grief, to lessen, to allay, to render tranquil.

Tell me, when shall these weary woes have end;
Or shall their ruthless torment never cease,

But all my days in pining languor spend,
Without hope of *assuagement* or release?

Spenser's Sonnets.

Shall I, t' *assuage*

Their brutal rage,

The regal stem destroy?

Dryden's Albion.

The rest

Was broiled and roasted for the future feast,

The chief invited guests were set around;

And, hunger first *assuag'd*, the bowls were crown'd,

Which in deep draughts their cares and labours
drown'd. *Id. Fables.*

If in the breast tumultuous joys arise,

Musick her soft *assuasive* voice supplies.

Pope's St. Cæcilia.

Refreshing winds the summer's heats *assuage*;

And kindly warmth disarms the winter's rage.

Addison.

Patroclus sat contentedly beside
Eurypylos, with many a pleasant theme,
Soothing the generous warrior, and his wound
Sprinkling with drugs *assuasive* of his pains.

Cowper's Iliad, bk. xv. p. 274.

ASSUEFAC'TION, } *Assuefacio*, *assuefac-*
AS'SUETUDE. } *tum*, to accustom. The
state of being accustomed.

We see that *assuetude* of things hurtful, doth make them lose the force to hurt.

Bacon's Natural History.

Right and left, as parts inservient unto the motive faculty, are differenced by degrees from use and *assuefaction*, or according whereto the one grows stronger.

Brown's Vulgar Errors.

ASSUME', } *Assumo*, *assumptum*, *ad*
ASSUMER, } and *sumo*, to take to [one's
ASSUMING, } self.] To appropriate, to
ASSUMPT', v. & n. } claim more than is due, to
ASSUMPTION. } arrogate, to suppose something granted without proof.

Preserve the right of thy place, but stir not questions of jurisdiction; and rather *assume* thy right in silence, and de facto, than voice it with claims and challenges.

Lord Bacon's Essays.

His majesty might well *assume* the complaint and expression of king David.

Clarendon.

With ravish'd ears

The monarch hears;

Assumes the god,

Affects to nod;

And seems to shake the spheres. *Dryden.*

His haughty looks, and his *assuming* air,

The son of Isis could no longer bear. *Id.*

This makes him over-forward in business, *assuming* in conversation, and peremptory in answers. *Collier.*

For spirits freed from mortal laws, with ease

Assume what sexes and what shapes they please.

Pope.

This, when the various god had urg'd in vain,

He strait *assum'd* his native form again. *Id.*

The personal descent of God himself, and his *assumption* of our flesh to his divinity, more familiarly to insinuate his pleasure to us, was an enforcement beyond all methods of wisdom.

Hammond's Fundamentals.

In every hypothesis something is allowed to be *assumed*.

Boyle.

Upon the feast of the *assumption* of the Blessed Virgin, the pope and cardinals keep the vespers.

Stillington.

Adam, after a certain period of years, would have been rewarded with an *assumption* to eternal felicity.

Wake.

It is scarce possible to conceive any scene so truly agreeable, as an assembly of people elaborately educated, who *assume* a character superior to ordinary life, and support it with ease and familiarity. *Usher.*

It very seldom happens that a man is slow enough in *assuming* the character of a husband, or a woman quick enough in condescending to that of a wife.

Steele.

Habits are soon *assumed*, but when we strive
To strip them off, 'tis being flayed alive. *Cowper.*

ASSUMENT. *Assuo*, to stitch or tack on.
A tacking on.

This *assument* or addition, Dr. Marshall says, he never could find any where but in this Anglo-Saxonick translation, and that very ancient Greek and Latin MS copy of Beza's.

Lewis's Editions of the Eng. Trans. of the Bible.

ASSUMPSIT, in the law of England, or promise, is of the nature of a verbal covenant, and wants nothing but the solemnity of writing

and sealing to make it absolutely the same. If therefore, it be to do any explicit act, it is an express contract, as much as any covenant: and the breach of it is an equal injury. The remedy indeed is not exactly the same: since, instead of an action of covenant, there only lies an action upon the case. for what is called an assumption or undertaking of the defendant; the failure of performing which, is the wrong or injury done to the plaintiff, the damages whereof a jury are to estimate and settle. As, if a builder promises or undertakes, that he will build and cover a house within a limited time, and fails to do it, an action on the case arises against the builder, and the party injured may recover a pecuniary satisfaction. But some agreements, though ever so expressly made, are deemed of so important a nature, that they ought not to rest on a verbal promise only, which cannot be proved but by the memory of witnesses, and which oftentimes leads to perjury. To prevent this, the statute of frauds and perjuries, 29 Car. II. c. 3. enacts, that in the five following cases, no verbal promise shall be sufficient to ground an action upon; but at the least some note or memorandum of it shall be made in writing, and signed by the party to be charged therewith: 1. Where an executor or administrator promises to answer damages out of his own estate. 2. Where a man undertakes to answer for the debt, default, or miscarriage, of another. 3. Where any agreement is made upon consideration of marriage. 4. Where any contract or sale is made of lands, tenements, or hereditaments, or any interest therein. 5. And lastly, where there is any agreement that is not to be performed within a year from the making thereof. In all these cases, a mere verbal assumption is void.

ASSUMPTION, a festival in the Romish church, in honor of the miraculous ascent of the Virgin Mary into heaven: the Greek church, who also observe this festival, celebrate it on the 15th of August with great ceremony.

ASSUMPTION, or **ASSONGONG**, one of the Ladone islands, in the Pacific Ocean. Father Gobien asserts that it is eight en miles in circumference; but Pouse diminishes its size to three. It is of a conical figure, rising 600 feet in height, of dreary aspect, and almost covered with lava from the eruptions of a volcano in the centre. A few coconut trees are found on the island; but there is no anchorage near the shore. Fifteen miles south of St. Lawrence. Long. 140° 55' E., lat. 19° 45' N.

ASSUMPTION, the capital city of Paraguay, in America. It is situated on the eastern bank of the river Paraguay, eighteen miles above its junction with the first mouth of the Pilcomayo. It was originally a small fort, built in 1538, and in 1547 was erected into a bishopric. It is now inhabited by about 500 families of Spaniards, and several thousand Indians and Meztizoes.

ASSUMPTIVE ARMS, in heraldry, are such as a person has a right to assume, with the approbation of his sovereign, and of the heralds: thus, if a person, who has no right by blood,

and has no coat of arms, shall captivate, in any lawful war, any gentleman, nobleman, or prince, he is, in that case, entitled to bear the shield of that prisoner, and enjoy it to him and his heirs for ever.

ASSURE,
ASSUR'ED,
ASSUR'ANCE,
ASSUR'EDLY,
ASSUR'EDNESS, } Fr. *assurer*, to make sure.
 To secure, to assert, aver,
 warrant, vouch, certify, in-
 spire with confidence.

What man is he that boasts of fleshly might,
 And vain assurance of mortality;
 Which all so soon, as it doth come to fight
 Against spiritual foes, yields by and by.

Faerie Queene.

I must confess, your offer is the best;
 And, let your father make her the assurance,
 She is your own, else you must pardon me;
 If you should die before him, where's her dower?
Shakespeare.

I hold the entry of common-places to be a matter of great use and essence in studying, as that which assureth copiousness of invention, and contracteth judgment to a strength.
Bacon's Essays.

An assurance, being passed through for a competent fine, hath come back again by reason of some oversight.
Id.

I revive
 At this last sight; *assur'd*, that man shall live
 With all the creatures, and their seed preserve.
Milton.

Well is that part of us lost which may give assurance of the salvation of the whole.

Hall's Contemplations.

Assuredly he will stop our liberty, till we restore him his worship.
South.

It is the ennobling office of the understanding to correct the fallacious and mistaken reports of the senses, and to assure us that the staff in the water is straight though our eye would tell us it is crooked.
Id.

The obedient, and the man of practice, shall outgrow all their doubts and ignorances; till persuasion pass into knowledge, and knowledge advance into assurance.
Id.

Hath he found in an evil course that comfortable assurance of God's favour, and good hopes of his future condition, which a religious life would have given him?
Tillotson.

ALMANZ. No; there is a necessity in fate;
 Why still the brave bold man is fortunate;
 He keeps his object ever full in sight,
 And that assurance holds him firm and right.
Dryden. Conquest of Granada, part i.

A man without assurance is liable to be made uneasy by the folly or ill-nature of every one he converses with.

Melmoth's Translation of Cicero's Laelius

How happy it is to believe with a steadfast assurance that our petitions are heard even while we are making them, and how delightful to meet with a proof of it in the effectual and actual grant of them.

Cowper's Letters.

The soul reposing on assured relief,
 Feels herself happy amidst all her grief;
 Forgets her labour, as she toils along,
 Weeps tears of joy, and bursts into a song.

Corp r.

A S S U R A N C E .

ASSURANCE, or **INSURANCE**, in commercial affairs. Under the latter word, every thing connected with the subjects, both of life and of marine insurance, might with great propriety be arranged. But mercantile usage, and the titles of various respectable societies in this country, have appropriated the former word to contracts for paying sums of money upon the continuance of life, or in the event of death; and the latter, to the insurance of property against the contingencies of the sea. We propose, under **LIFE ANNUITIES**, to enter further into the principles on which the contingency of life is calculated; under **MARINE INSURANCE**, to treat of all that is usually comprised under that head; confining ourselves in this paper to the practical detail of the methods adopted by the most respectable Assurance companies in the conduct of their affairs, and the actual calculations on which they proceed.

Assurance on lives is the guaranteeing a certain sum of money to be paid in the event of a person named being alive at a certain time, or dying within a certain time, or to be paid within a certain time after the death of a person named. The party agreeing to pay this sum, is termed the Assurer; the sum he receives for his hazard, or in compensation for what he is to pay, is called the Premium of assurance; and the instrument by which the parties are mutually bound to their contract, is called a Policy of assurance. These are granted sometimes by individuals; but in this case the policies, though often for larger sums than the companies insure, are usually for short periods, and at higher rates than the companies charge. It must be obvious, that as they are particular bargains between individuals under circumstances known, particularly, perhaps, or that ought to be known by those concerned, no uniform plan of proceeding can be expected.

But the respectable societies who conduct this business in the metropolis, and other parts of Great Britain, proceed upon settled and mathematical principles. Tables of the ordinary duration of human life, formed from bills of mortality, are the basis of their calculations. The register of mortality at Northampton, originally published by Dr. Price, is that generally adopted; it having been found by long experience that rather fewer deaths happen, according to the books of the Equitable Assurance Society, than are upon that scale to be expected. The most esteemed tables are those of Aikin, De Parcieux, Kerseboom, and Gorsuch. M. de Moivre assumes, that if eighty-six persons were born at the same time, one would die in each year, until the whole number ceased to live. Although this hypothesis has not been found accurate enough for extensive business in this way, it furnishes an easy rate for estimating the expectation of life. Subtract the given age of a person from 86; when, dividing the quotient by two, the remainder gives the expectation nearly. Thus, let the

age be 40, then $\frac{86-40}{2}$ is 23, which differs very

little from the Northampton table. At the age of 50 again, the error is trifling, the Northampton table giving 17.99, De Moivre's, 18. But, in the higher ages, the error becomes considerable.

A scale of life having been adopted, the table of premiums to be paid by the parties insuring, is calculated in the following manner:—The premium for a certain age being supposed to be known, then the premium for a person of one year younger, being compounded of the premium for one year and the present value of the above premium, is easily calculated from the table of lives, thus:—Multiply the premium on the oldest life into the number of persons alive in the tables of that age, and divide by the number of persons of the younger age alive in the tables. This sum, discounted for a year, gives the premium for assuring the desired sum at the end of the year. Then multiply the sum to be assured into the number of persons of the younger age, that die according to the tables in a year, and divide by the number of persons alive at that age, and this sum discounted for a year is the assurance of the sum for the first year, and consequently the two sums, added together, give the desired premium. Now, as the oldest person in the scale of life dies in the ensuing year, the premium on him is evidently the sum to be paid discounted for one year, and thence the premium for the age below is ascertained by the above rule; and so of every age in succession. Errors cannot be committed on this plan without detection, as every step is checked by a similar table drawn out for the value of an annuity at each age. In the same manner are tables formed for the assurance of a sum payable at the death of one out of two persons, or at the death of the survivor of two persons, or at the death of one on the contingency of his surviving another, and so on. The tables generally adopted by the companies, on the contingency of one person surviving another, being calculated by an approximation, founded on the expectation of their lives, do not partake of the mathematical accuracy of the other tables; but the companies, in this case, grant assurances at times to their own disadvantage; for if they take rather too much upon one life, they lose that sum upon the other; the premium payable on the death of one of two parties, being divided by the above-mentioned rule of approximation into two premiums, to be paid by the two parties on the contingency of one surviving the other. These rules apply to tables of rates for the payment of a gross premium: but as it is generally more convenient to pay an equivalent annual sum, a table of rates is made for this case, which is formed by dividing the gross premium by the value of an annuity upon each age added to unity. If the annual premium were paid at the end of the year, the addition of unity would be unnecessary; but a policy is not granted till one premium is paid, and hence the necessity of the addition is obvious.

Premiums being thus settled from a fixed table of observations on life, it is evident that, unless

the deaths happen exactly in the order prescribed by the tables, there will be a surplus or deficiency of capital for the payment of the assured sums. The management of the surplus, or apprehended surplus, which the prudence of respectable companies generally insures, is different in different companies. Either the company appropriates the whole of the surplus to itself, or makes a compensation to the assured for it. In the former case, the company pays the sum specified in the policy, and no more; consequently, a party may pay to the office a sum far greater than his executors or assigns receive in return. Thus, if an assurance is effected on a person between sixteen and seventeen for £100, receivable at his death, the annual premium is £2. 0s. 8d.; and if he lives forty-nine years, he will have paid more than the whole sum to be received, without computing interest on these payments. The surplus of the accumulation of premiums above the claims may be great from two causes: first, the increased interest obtained by the company above that by which the table of rates was computed; and, second, a longer duration of life in the earlier years than is assigned by the table; and here great circumspection on the part of the company is requisite to preserve it from imposition, and to secure the best lives that circumstances admit. In the companies where only the sum specified in the policy is paid, the surplus does not go entirely to the company; for it is common in these offices to allow a per centage on the premium to the party who brings an assurance to them, generally a solicitor, who thus participating in the gains of the company, has an interest in increasing its concerns, though to the evident disadvantage of his client.

Where the surplus is made advantageous to the assured, two methods are adopted; the one is to add, at certain periods, a sum to each policy; the other to diminish the premium. In both cases a valuation is made of all the annual premiums, with the past and future expected accumulations, and also of the claims upon every policy. If the former exceed the latter to a sufficient amount, then an addition is made to each policy, or the premium is diminished. It is necessary, however, that the utmost care should be taken to secure to each policy the sum named in it, with every addition made to it; and hence a third part of the surplus is constantly retained to guard against possible contingencies. This reservation has occasioned a singular anomaly in one of the most distinguished companies for life assurance. In that company all are partners, being mutually guarantees to each other for the payment of their respective claims. The surplus arising from the excess of premiums, with their accumulations above the claims, evidently belongs to the whole company, and consequently each partner is entitled to a portion of it. But of this surplus, a third being constantly reserved, and each person at his death ceasing to be a partner, every person leaves behind him a portion for his successors. Such has been the extreme caution of the Equitable Society.

This led to the formation of a plan, which is

adopted by the Rock Assurance Society, that vests this third in determinate hands. To do this, the company consists of a number of proprietors, each of whom is bound to keep up an assurance with it, and whose interest in these assurances is greater than that derived from the profit of assurances granted to non-proprietors. The company takes upon itself the whole risk of policies made with it, being bound to pay to each party assured the sum specified in his policy; and additions are made to each policy in the manner above-mentioned. But the third reserved is joined to, and makes part of the subscription capital stock; and the interest upon it is annually divided among the proprietors. Thus the third reserved belongs to, and continues to add to, the security of the company; and the non-proprietor, secured from all risk, participates in the two-thirds divisible at every period.

Other modes are sometimes adopted to dispose of accumulating property; such as, by diminishing, at certain periods, the premiums paid on assurance; in this case the sum specified in the policy is paid, though the party assured may have paid a much less sum than in the companies above mentioned. The diminution of premium depends on the excess of capital in hand, with the present value of future premiums, above the claims that are or may be made upon it, and consequently the same care is necessary to reserve a part of the surplus for fear of future contingencies. The public have thus a choice either to receive a fixed or an increasing sum; the fixed sum by means of a definite or a probably decreasing premium, and an increasing sum by means of a definite premium.

Assurance policies are generally confined to the limits of Europe, but they are capable of being extended to all parts of the world. In such cases an addition is made to the premium, according to the supposed addition to the risk from unhealthiness of climate, and danger of the seas. Additions are also made to the premium on account of the profession (as of the army) of the assured; on account of disease, as of gout, by which he is occasionally afflicted; or of diseases, as of small-pox and measles, to which he may be liable.

The oldest of the societies for assurances on lives in London, is the Amicable Society, instituted by charter in the year 1706. The same contribution was originally required from every member, whatever his age might be, and the sums received at the death of members were variable, depending on the number of persons that died in the same year. Subsequent alterations were made in this company by successive charters. At present the several interests of the members are divided into shares, each share being now warranted to produce £200 at the death of the insured, together with such additions as may arise from the circumstances of the year in which the death happens; and any number of shares, and half shares, not exceeding sixty-five shares, may be granted on one and the same life, by which assurances may be effected from £200 to £5000, and participate in the benefits of the society.

The Royal Exchange Assurance Company re-

ceived its charter in 1720, and is principally engaged in insuring ships and goods at sea, and of houses and goods from fire; but it also grants annuities and assurances on life. In the latter, it confines itself to the payment of the sum assured.

The Equitable is the most considerable in point of numbers, and, on the whole, perhaps the most respectable of the societies for the assurance of lives, to which it is chiefly confined. In this society all are partners, and mutually assurers of each other. It arose from small beginnings, and has made considerable alterations from the rate of its first premiums, till it settled in the table annexed to this article, which is that generally adopted by these associations. At certain periods additions have been made to the policies; and, in this manner, its affairs were conducted till December 7, 1809, when a change took place respecting the members then assured, namely, that instead of waiting till the end of the next interval, for assigning a sum out of the accumulations to each policy, every member should have two per cent. annually assigned to his policy, during the years of this period. Consequently, all holders of policies, prior to the year 1810, will leave to their heirs the sum assured by the policy, together with its accumulations up to the year 1810, and also two per cent. per annum for his life, within 1810 and 1820; but this benefit does not accrue to members entering at the close of the year 1809. Whether this plan can be continued or extended, time will show. The number of the members in this society made it necessary to change some of their regulations respecting votes; and it was wisely resolved, that persons becoming members, after the 19th December 1809, should not have a vote at the general meetings, unless they had been assured for five years, for the whole continuance of life, in the sum of £2000; and to be a director, the qualification is an assurance of £5000 for the same time, which must have been held for five years.

The history of this society is very important, and has been well treated by Dr. Price, in his *Observations on Reversionary Payments*, and by Mr. Morgan. In consequence of the connexion of Dr. Price with this institution, he drew up his remarks on the various societies which soon after sprung up, and whose names, but for his notice of them, would now be forgotten. They were formed chiefly about the years 1770 and 1771, offering very fallacious terms to the public, by which the aged were benefited at the expense of their juniors; and the evil is not yet cured.

For some time no other important society arose; but, in the year 1792, the Westminster Life Assurance was formed. The Pelican in 1797; the Globe in 1799; the Albion in 1805; the Rock and the Provident in 1806; the Eagle, Hope, London Life Association, and Atlas, in 1807. The Rock and Equitable we have noticed.

The Provident combines with life, policies on fire; but it assigns also, at certain times, additions to its policies. The Hope is also a fire and life office, and both are proprietary companies.

The rates in these societies are the same as those in the Equitable and Rock.

The Albion and the Globe are life and fire assurance companies; their rates are also the same. They pay also the sum assured; but a liberal commission is allowed to solicitors, and to others who effect assurances.

The London Life Association is confined entirely to life assurances; but it differs from the others in this, that its aim is, that the benefits resulting from its transactions shall be enjoyed by the members during life; in other words, the society assures to a person the sum named in the policy, and no more; but at certain times it considers whether the surplus of the accumulations above the claims is sufficient to admit of a diminution of premium, and one is made accordingly. In this society all are members and assurers one of the other, and consequently the surviving members at any time are bound to make up the deficiency, if any should arise by this mode of arrangement. This could be done by raising, in the first instance, the premiums that have been lowered; and it is very improbable, that, with good management, any thing farther would be necessary. In imitation of these London Companies, several have been formed throughout the country.

The practical mode of effecting an assurance in these societies is as follows: The party desirous of effecting an assurance, receives from the office of the company a printed paper called a declaration, which he fills up with the name of the party to be assured, his age, the place and time of his birth, and place of his present residence, with certain particulars as to his health. This declaration is then duly signed; and it contains a clause, stating, that any falsehood in the declaration invalidates the policy. To corroborate the statement, references are given to two persons well acquainted with the party on whom the assurance is made, one of whom is to be a medical person, and sometimes more references are required. The reasons for these precautions are obvious.

When the declaration has been thus completed, the person by whom the assurance is made makes his appearance before the directors of the company, who enquire into the general state of his health, and a minute is entered in their books accordingly. The letter of the referees, with the declaration, are subsequently laid before the court, which from these documents, and information frequently derived from other sources, forms its decision; and this is entered on the minutes of the court, and communicated to the applicant. A certain time is allowed for the payment of the premium; and if it is not paid within that time, the assurance cannot be effected, but by a fresh application to the court, according to the forms above mentioned. On the payment of the premium a receipt is given, containing the number of the policy, which is then made out according to the declaration, inspected by the court, signed by a certain number of directors, and delivered to the other party interested in it.

If the person, on whose life the assurance is made cannot appear before the directors, or any

one appointed by them for that purpose, an additional sum is charged for non-appearance. There is also a duty to be paid to government on each policy, and this, with a small entrance fee, makes an addition to the first year's premium. But the premium itself is only named in the policy, as on the future payment of this sum its existence depends.

A policy is assignable; and it often forms a security for sums advanced, and not unfrequently becomes an object of sale. In these cases, the holder of the policy pays the future premiums, and the advantage of a purchaser consists in holding a policy at a less premium than he must have paid at the present age of the party, on whose life the assurance was made. Thus, supposing a policy to have been granted for the payment of a thousand pounds, at the death of a party aged between thirty-seven and thirty-eight, when the policy was made; suppose it is sold when the party is between fifty and fifty-one; the purchaser will have to pay £32. 5s. annually, during the existence of the policy: whereas, if he had taken out a policy at the present age of the party, his premium would be £46. 15s. For the difference between these two sums, namely £14. 10s., a price is fixed on; but it is to be observed, that, in the sale of a policy in the market, this disadvantage attends it,—that the bidders, not being acquainted with the person on whose life the policy is made, and being liable to trouble and expense, to ascertain that he is alive at each payment of the premium, must make a deduction on this account, from what they might otherwise presume to be a compensation for the difference between the two premiums.

On the death of the party on whom the claim depends, certain documents are required, such as the register of the burial of the deceased; and references to the medical persons or others who attended him in his last illness; and, if he effected the policy himself, the probate of his will, or, if it has been assigned to another, the copy of the assignment. The grounds of these precautions are, with respect to the receiver of the sum assured, obvious; and the nature of the death must be ascertained; as, in case of suicide, or dying by the hands of justice, or on a voyage on the high seas, without licence from the company, (except, in general, in going from one part in the united kingdom to another,) the policy is vitiated. In the interval between the notice of the party's death, and the time assigned for the payment of the claim, due investigation is made; and, every thing having been found satisfactory, the claimant brings with him the policy and a receipt for the sum claimed, which is immediately paid to him; the seals are torn from the policy, and the contract is at an end. In the

case that a claim is payable, in the event of a person being alive at a certain time, his appearance before the court is requisite, or sufficient proof must be given that he was alive at the time defined by the policy.

Policies depending on a person being alive at a certain time, are very rare, and chiefly confined to endowments for children, in which case the payment of a gross sum down, or of an annual payment till the child attains the age of twenty-one, secures to that child, at that age, the sum named in the policy. This mode of assurance has led some offices to compose a table of rates, according to which, a person at the age of twenty is required to pay a premium, which would produce at legal interest more than he would receive at the expiration of the year, from the company; and thus a person, if any such could be found, to effect an assurance of this kind, would run the risk of losing the sum assured, and receive, if successful, not so much as he could have attained without any risk at all.

On the whole, the doctrine of assurance must always be considered a subject of the first importance, in a commercial state like that of Great Britain, and to involve an immense number of interests. When we consider the thousands of families in this country, who are living in a state of comparative affluence, without possessing any, or very little, disposable property; whose income, in fact, depends almost entirely on the exertions of the head of the family, and with the extinction of whose life every source of income ceases; when we contemplate the poverty and distress in which many widows, with their helpless children, would be plunged by such an event, we cannot estimate too highly the advantages which are held out by those societies, who, on honorable principles, furnish the means whereby every provident father and husband may, in part, avert the consequences of a premature death; to which every one is liable, and against which event every man ought to be provided. Perhaps, no part of the civil economy of this country shows more decidedly the high moral state of the middling classes of the people, than the immense amount of life assurances effected in the different offices of the metropolis, and in those of like local companies in several of the counties in England; nor, perhaps, can we have a stronger instance of the high degree of confidence that the people are disposed to place in the moral rectitude of the government; by far the greater part of the capital of the companies to which we have alluded being invested under government securities.

The following is a table of the rates generally acted upon by the Life Assurance Offices in the capital.

ASSURANCE OF SINGLE LIVES.							SURVIVORSHIP OF A LIFE ASSURED.			ASSURANCE ON TWO JOINT LIVES.								
To secure a Sum to the Nominee, or to the lawful Representatives of the Assured.							To secure a Sum to the Nominee or lawful Representatives of the Assured, in case a Person named shall survive another.			To secure a Sum, payable when either of Two Persons named shall happen to die.								
Age.	Premium per cent. if assured from year to year.			Premium per cent. per an. if assured for seven years.			Premium per cent. per an. if assured for the whole term of life.			Age of the life assured.	Age of the life against which the assured is made.	Premium per cent. per annum.	Age.	Age.	Premium per cent. per annum.

ASSURGENT LEAVES, in botany, denote such as are first bent down, and then rise erect towards the apex.

ASSUS, or Assos, in ancient geography, a town of Troas, though by others supposed to be of Mysia, and the same with Apollonia, but different from the Apollonia on the Rhyndacus. Ptolemy places it on the sea coast, but Strabo more inland. It was the country of Cleanthes, the stoic philosopher, who succeeded Zeno. St. Luke and others of St. Paul's companions in his voyage, Acts xx. 13, 14, went by sea from Troas to Assos: but St. Paul went thither by land; and, meeting them at Assos, they all went together to Mitlene.

ASSYRIA, an ancient kingdom of Asia, concerning the extent, commencement, and duration of which, historians differ greatly in their accounts. Several ancient writers, in particular Ctesias and Diodorus Siculus, have affirmed that the Assyrian monarchy, under Ninus and Semiramis, comprehended the greater part of the known world. Had this been the case, it is not likely that Homer and Herodotus would have omitted a fact so remarkable. The sacred records intimate that none of the ancient states or kingdoms were of considerable extent; for neither Chedorlaomer nor any of the neighbouring princes were tributary or subject to Assyria; and we find nothing of the greatness or power of this kingdom in the history of the judges and succeeding kings of Israel, though the latter kingdom was oppressed and enslaved by many different powers in that period. It is highly probable, therefore, that Assyria was originally of small extent. According to Ptolemy, it was bounded on the north by Armenia major; on the west by the Tigris; on the south by Susiana; and on the east by Media.

The revolutions of the Assyrian monarchy were numerous. Its founder was Ashur, the second son of Shem, who went out of Shinar, either by the appointment of Nimrod, or to elude the fury of that tyrant; conducted a large body of adventurers into Assyria, and laid the foundation of Nineveh, Gen. x. 11. These events happened not long after Nimrod had established the Chaldean monarchy, and fixed his residence at Babylon. The Persian historians suppose, that the kings of Persia of the first dynasty were the same with the kings of Assyria, of whom Zolath, or Nimrod, was the founder of Babel. Herodot. Orient. Bib. v. Bagdad. It does not, however, appear, that Nimrod reigned in Assyria. The kingdoms of Babylon and Assyria were originally distinct and separate, Micah v. 6; and in this state they remained until Ninus conquered Babylon, and made it tributary to the Assyrian empire. Ninus, the successor of Ashur, Gen. x. 11, Diod. Sic. lib. 1, seized on Chaldea, after the death of Nimrod, and united the kingdoms of Assyria and Babylon. This prince is said to have subdued Asia, Persia, Media, Egypt, &c. If he did so, the effects of his conquests were of short duration; for in the days of Abraham we do not find that any of the neighbouring kingdoms were subject to Assyria. He was succeeded by Semiramis, a princess of heroic mind; bold, enterprising, fortunate; but of whom many fabulous things have been recorded. It appears, however, that there were two

princesses of the same name, who flourished at very different periods. One of them was the consort of Ninus; and the other lived five generations before Nitocris, queen of Nebuchadnezzar, Euseb. Chron. p. 58. Herod. lib. 1, cap. 184. This fact has not been attended to by many writers. Whether there was an uninterrupted series of kings from Ninus to Sardanapalus, or not, is still a question. Some suspicion has arisen, that the list which Ctesias has given of the Assyrian kings is not genuine; for many names in it are of Persian, Egyptian, and Grecian extraction. Nothing memorable has been recorded concerning the successors of Ninus and Semiramis. Of that effeminate race of princes it is barely said, that they ascended the throne, lived in indolence, and died in their palaces at Nineveh. Diodorus relates, that in the reign of Teutames, the Assyrians solicited by Priam their vassal, sent to the Trojans a supply of 20,000 foot and 200 chariots, under the command of Memnon, son of Tithonus, president of Persia. But this is not confirmed by any other author. Sardanapalus was the last, and by all accounts the most effeminate of the ancient Assyrian kings. Historians have unanimously reprobated his character; and Lord Byron has made it the foundation of a beautiful poem. We have only to add, that Arbaces, governor of Media, taking advantage of Sardanapalus's indolence, withdrew his allegiance and rebelled against him. He was encouraged in this revolt by the advice and assistance of Belesis, a Chaldean priest, who engaged the Babylonians to follow the example of the Medes. These powerful provinces, aided by the Persians and other allies, who despised the effeminacy, or dreaded the tyranny of their Assyrian lords, attacked the empire on all sides. Their most vigorous efforts were, in the beginning, unsuccessful. Firm and determined, however, in their opposition, they at length prevailed; defeated the Assyrian army, besieged Sardanapalus in his capital, which they demolished, and became masters of the empire A. A. C. 821. The Assyrian empire was now divided into three kingdoms, viz. the Median, Assyrian, and Babylonian. Arbaces retained the supreme power and authority, and fixed his residence at Ecbatana in Media. He nominated governors in Assyria and Babylon, who were honored with the title of kings, while they remained subject and tributary to the Median monarchs. Belesis received the government of Babylon as the reward of his services; and Phul was entrusted with that of Assyria. The Assyrian governor gradually enlarged the boundaries of his kingdom, and was succeeded by Tiglath-pileser, Salmansar, and Sennacherib, who asserted and maintained their independency. After the death of Esar-haddon, the brother and successor of Sennacherib, the kingdom of Assyria was split, and annexed to the kingdoms of Media and Babylon. Several tributary princes afterwards reigned in Nineveh; but no particular account of them is found in the annals of ancient nations. We hear no more of the kings of Assyria, but of those of Babylon. Cyaxares, king of Media, assisted Nebuchadnezzar, king of Babylon, in the siege of Nineveh, which they took and destroyed, A. A. C. 606.

The most remarkable provinces of Assyria

were, 1. Arapachitis, bordering on Armenia. 2. Corduene, a mountainous territory, the ancient residence of the Carduchi, mentioned by Xenophon in his Anabasis. 3. Adiabene, in Strabo's time, the most considerable province in Assyria. 4. Calachene, lying between the mountains of Armenia and Zabus Major. 5. Apolloniatis, watered by the river Gorgus. 6. Settacene, by some reckoned a portion of Babylonia. 7. Chalontis, separated from Media by a branch of Mount Taurus.

ASSYRIAN LETTERS, a denomination given by several Rabbins and Talmudists, to the characters of the present Hebrew alphabet, as supposing them to have been borrowed from the Assyrians during the Jewish captivity in Babylon.

ASTA, an inland town of Liguria, a Roman colony, on the river Tanarus, now called Asti.

ASTA, or **ASTA REGIA**, a town of Bætica, situated at the mouth of the Bætis, which was choked up with mud, north of Cadiz, and sixteen miles distant from its port. Its ruins show its former greatness. Its name is Phœnician, denoting a frith or arm of the sea. It is said to be the same with the present Xeres.

ASTABAT, a town of Armenia, in Asia, three miles from the river Aras, and twelve south of Nakhshivan. The land about it is excellent, and produces very good wine.

ASTÆUS, a species of the crab insect.

ASTAKILLOS, a denomination given by Paracelsus to a malignant gangrenous ulcer in the legs, occasioned by a mercurial sult in the blood. It is also called by him araneus, and ulcus araneum, the spider's ulcer.

ASTANDA, in antiquity, a royal courier or messenger; the same with Angarus. Darius king of Persia, is said by Plutarch, in his book on the fortunes of Alexander, to have formerly been an astanda.

ASTARILÆ, **ASTARITÆ**, or **ASTAROTHITES**, a name given to those Jews who worshipped Astaroth.

ASTARTE, in ancient geography, a city on the other side Jordan; one of the names of Rahbah Ammon, in Arabia Petraea.

ASTARTE, in pagan mythology. See **ASHTAROTH**. On a medal of Cæsarea Palestina, Astarte is represented as in the annexed figure, in a short habit, crowned with battlements, holding the head of Osiris in her right hand, and a staff in her left, inscription *COLonia Prima Felix Augusta Flavia Commodiana, &c.*

ASTATE. See **ESTATE**.

The worlde stante ever upon debate,
So maie be siker none *astate*,
Now here, now there, now to, now fro,
Now up, now down, the world goth so,
And ever hath done, and ever shall.

Gover. Con. A. The Prologue.

ASTATI, in the ninth century, the followers of one Sergius, who renewed the errors of the Manichees. They prevailed much under the emperor Nicophorus; but his successor, Michael Curopalates, curbed them with very severe laws.

ASTEERING. In steeping. See **STEEP**.

Where Perah's flowers
Perfume proud Babel's bowers,
And paint her wall:
There we lay'd *asteering*
Our eyes in endless weeping,
For Sion's fall.

P. Fletcher's Poems, p. 163.

ASTEISM, in rhetoric, a pleasant kind of irony, or handsome way of deriding another. Such, e. g. is that of Virgil:

Qui Bavium non odit, amet tua carmina, Mavi, &c

ASTELL (Mary) was the daughter of an opulent merchant at Newcastle-upon-Tyne, where she was born about 1668. She was educated in a manner suitable to her station; and amongst other accomplishments was mistress of the French, and had some knowledge of the Latin tongue. Her uncle, a clergyman, observing in her marks of a promising genius, took her under his tuition, and taught her mathematics, logic, and philosophy. She left the place of her nativity when she was about twenty years of age, and spent the remaining part of her life in London and at Chelsea. Here she pursued her studies with great assiduity, made great proficiency in the above-mentioned sciences, and acquired a more complete knowledge of the classics. Amongst these Seneca, Epictetus, Hierocles, Antoninus, Tully, Plato, and Xenophon were her favorites. She wrote, 1. A Serious Proposal to the Ladies. 2. An Essay in Defence of the Female Sex. 3. Letters concerning the Love of God. 4. Essays upon Marriage, Crosses in Love, and Friendship. 5. Moderation truly stated. 6. The Christian Religion, as professed by a daughter of the Church of England. 7. Bart'lemy Fair, or an Enquiry after wit; and other works. She died in 1731, aged sixty-three, and was buried at Chelsea.

ASTENA, a genus of worms of the mollusca order, in the Linnæan system.

ASTER, in ancient pharmacy, a kind of medicine, invented by Andromachus, against defluxions and divers pains.

ASTER, in botany, starwort, a genus of the polygamia superflua order, and syngenesia class of plants; ranking in the natural method under the forty-ninth order, *compositæ discoides*. The receptacle is naked; the pappus simple; the rays of the corolla ten; and the calyx imbricated. There are above thirty species. All of them may be raised from seed sown either in autumn or spring: but the greater part being perennial plants, and increasing greatly at the roots, are generally propagated by parting their roots early in the spring. They will grow in almost any soil or situation; and the larger sorts increase very fast. They grow best in the shade: the lower kinds do not run so much at the root, but should be taken up and transplanted every other year; which will make them produce much fairer flowers. Some few sorts which are natives of warm climates, will require artificial heat to raise them, if not to preserve them.

ASTER, in mineralogy, a species of Samian earth.

ASTERABAD, a small province of Persia, bounded on the west by the Caspian sea, on the

south by the districts of Damgan and Bistan, and on the north and east by the river Ashor. This province is the ancient Hyrcania, and the paternal estate of the present king of Persia, as chief of the tribe Kajar, or Kujur, which has entire possession of it. The capital is situated on the south-east shore of the Caspian sea, at the mouth of the river Aster, or Ester. It was destroyed by Tamerlane, and is now governed by a descendant of the reigning family of Persia. 300 miles N. N. E. of Ispahan. Long. 54° E., lat. 36° 44' N.

ASTERAC, or ESTERAC, a ci-devant district of France, in Armagnac, now included in the department of Gers. It is fertile and populous.

ASTERIA, a gem, sometimes called the cat's eye, or oculus felis. It is a very singular and beautiful stone, and somewhat approaches to the nature of the opal, in having a bright included color, which seems to be lodged deep in the body of the stone, and shifts about, as it is moved, in various directions: but it differs from the opal in all other particulars, especially in its want of the great variety of colors seen in that gem, and in its superior hardness. It is usually found between the size of a pea and the breadth of a sixpence; is almost always of a semicircular form, broad and flat at the bottom, and rounded and convex at the top; and is naturally smooth and polished. It has only two colors, a pale brown and a white: the brown seeming the ground, and the white playing about in it, as the fire color in the opal. It is considerably hard, and will take a fine polish, but is usually worn with its native shape and smoothness. It is found in the East and West Indies, and in Europe. The island of Borneo affords some very fine ones, but they are usually small; they are very common in the sands of rivers in New Spain; and in Bohemia they are often found immersed in the same masses of jasper with the opal.

ASTERIA, an extraneous fossil, called in English the star-stone. These fossils are small, short, angular, or sulcated columns, between one and two inches long, and seldom above a third of an inch in diameter: composed of several regular joints; when separated, each resembles a radiated star. They are not without reason, supposed to be a part of some sea-fish petrified, probably the asterias or sea-star. The asteria is also called astrites, astroites, and asteriscus. They may be reduced to two kinds: those whose whole bodies make the form of a star; and those which in the whole are irregular, but are adorned as it were with constellations in the parts. The asterias spoken of by the ancients appears to be of this latter kind. The quality of moving in vinegar, as if animated, is scarcely perceivable in the astrites, but is signal in the asteria. The former must be broken in small pieces before it will move; but the latter will move, not only in a whole joint, but in two or three knit together. The curious frequently meet with these stones in many parts of England.

ASTERIA, in zoology, a name by which some authors have called the falco palumbarius, or os-hawk. See FALCO.

ASTERIAS, star-fish, or sea-star, in zoology, a name of objects of the order of vermes mol-

lusca. It has a depressed body, covered with a coriaceous coat; is composed of five or more segments, running out from a central part, and furnished with numerous tentacula; and has the mouth in the centre. The tentacula resemble the horns of snails, but serve the animal to walk with. They are capable of being contracted or shortened: and it is only at the creatures moving that they are seen of their full length; at other times, no part of them is seen but the extremity of each, which is formed like a sort of button, being somewhat larger than the rest of the horn. Aristotle and Pliny called this genus $\alpha\sigma\tau\eta\rho$, and stella marina, from their resemblance to the pictured form of the stars of heaven; and they asserted that they were so exceedingly hot, as instantly to consume whatsoever they touched! The fossil world has been greatly enriched by the fragments and remains of the several pieces of star-fish which have been converted into stones. See ASTERIA. There are many species of this genus: some of twelve, thirteen, and even fourteen rays. Most of them are found in our seas. We enumerate the principal: 1. *A. caput medusæ*, or arborescent sea-star, having five rays issuing from an angular body; the rays divided into innumerable branches, growing slender as they recede from the base. These the animal, in swimming, spreads like a net; and when he perceives any prey within them, draws them in again. It is called by some the Magellanic star-fish, and basket-fish. 2. *A. clathrata*, or cancelled sea-star, with five short thick rays, hirsute beneath, cancelled above, is found on our coasts, but is rare. 3. *A. decacnemus* having ten very slender rays, with numbers of long beards on the sides; the body small, and surrounded beneath with ten filiform rays. It inhabits the western coasts of Scotland. 4. *A. glacialis*, with five rays, depressed, round at the base, yellow, and having a round striated operculum on the back, is the most common; it feeds on oysters, and is very destructive to the beds. 5. *A. hispida*, with five rays, broad, angulated at top, and rough, with short bristles, is of a brown color, and found about Anglesea. 6. *A. oculata*, with five smooth rays, dotted or punctured, is of a fine purple color, also found about Anglesea. 7. *A. placenta*, with five very broad and membranous rays, extremely thin and flat, found about Weymouth. 8. *A. spherulata*, with a pentagonal indented body; a small globular head between the base of each ray; the rays slender, jointed, taper, and hirsute on their sides; found off Anglesea.

ASTERIAS, in ornithology, the ancient name of the bittern. See ARDEA.

ASTERION, in astronomy, one of the canes venatici.

ASTERISCUS, in botany, asteriodes buphthalmum, the ox eye.

ASTERISK, \ast Gr. $\alpha\sigma\tau\epsilon\rho\iota\sigma\kappa\omicron\varsigma$, a diminutive ASTERISM. \dagger Of $\alpha\sigma\tau\eta\rho$, a star. Asterisms denote a number of stars, a constellation. Asterisk is a character of reference used in printing, resembling a small star.

Dwell particularly on passages with an *asterism*, for the observations which follow such a note, will give you a clear light. *Dryden's Dufrenoy.*

Poetry had filled the skies with *asterisms*, and histories belonging to them; and then astrology devises the feigned virtues and influences of each.

Bentley's Sermons.

He also published the translation of the Septuagint by itself; having first compared it with the Hebrew, and noted by *asterisks* what was defective, and by obelisks what was redundant.

Grew.

ASTERIUS, or **ASTURIUS**, a Roman consul, who lived about A. D. 449. He wrote A Conference on the Old and New Testament, in Latin verse, which is extant, and in which each strophe contains, in the first verse, an historical fact in the Old Testament, and in the second an application of that fact to some point in the New.

ASTEREN. On the stern. See **STERN**.

Having left this strait *astern*, we seemed to be come out of a river of two leagues broad, unto a large and main sea.

The World encompassed by Sir F Drake, 1578.

The galley gives her side, and turns her prow,

While those *astern* descending down the steep,

Through gaping ways behold the boiling deep.

Dryden.

But at seven in the evening, finding we did not near the chase, and that the Wager was very far *astern*, we shortened sail, and made a signal for the cruizers to join the squadron.

Anson's Voyage, p. 50.

ASTEREN is used to signify any thing at some distance behind the ship; being the opposite of a-head, which signifies the space before her. See **AHEAD**.

ASTEROPEÛS, a Trojan hero, who fought with Achilles, in single combat, and proved him not invulnerable, by wounding him in the right arm; notwithstanding which Achilles slew him.

ASTEROPHYTON, in natural history, a kind of fish composed of a great number of cylindrical rays, each branching out into several others, so as to represent the branched stalks of a very intricate shrub.

ASTEROPODIUM, a kind of extraneous fossil, of the same substance with the *asteriæ* or star-stones, to which they serve as a base. See **ASTERIA** and **STAR-STONE**.

ASTESAN, the ancient county of Asti, a district of Upper Italy, bounded by Chieri and Carmagnola on the west, by the Vercellois on the north and east, and by the marquiseat of Gorzegno on the south. It is a fruitful and populous territory, about twenty-five miles long and ten broad, and belongs to the house of Savoy. It produces excellent wines, and exports to various parts of Italy large quantities of olives.

ASTETE'S ISLAND, an island to the north-west of the gulf of Carpentaria, New Holland, containing some traces of iron ore, and well wooded.

ASTHMA, a frequent, difficult, and short respiration, joined with a hissing sound and a cough, especially in the night-time, and when the body is in a prone posture; because then the contents of the lower belly bear so against the diaphragm, as to lessen the capacity of the breast, whereby the lungs have less room to move. See **MEDICINE**.

ASTI, a city of Montserrat in Italy, capital of the county. It has a bishop's see; is well fortified with strong walls and deep ditches: and is divided into the city, borough, citadel, and castle.

There are a great many churches, convents, and other handsome buildings in it. It is seated on the Tanaro, twenty-four miles east of Turin. Population 22,000. The inhabitants carry on a considerable trade in corn, wine, and silk, which is promoted by the situation of the town on the high-road from Alessandria to Turin.

ASTIGI, in ancient geography, a colony, and conventus juridicus, of Bœtica, situated on the Singulus, which falls into the Bætis; called also Colonia Astigitana, and Augusta Firma; now Ecyá, midway between Seville and Corduba.

ASTIPULATE, } To make an agreement.

ASTIPULATION. } See **STIPULATE**.

I do by my royal authority, confirm to persons of monastical religion, and by the consent and *astipulation* of my princes and peers do establish and consign to them that monastery.

Bp. Hall's Polemical Works, p. 187.

Shortly, all, but a hateful Epicurus, have *astipulated* to this truth.

Id. Devotional Works.

ASTIPULATOR, among the Roman Catholics, he by whose consent and leave a nun takes the religious habit.

ASTLE (Thomas), an English antiquary, was the son of a farmer in Staffordshire. After he had received a liberal education, Mr. Grenville took him under his patronage, and about 1763 gave him a place along with Sir Joseph Ayloffé and Dr. Ducarel, in the superintendance of the Westminster records. In 1766 he was chosen to conduct the printing of the ancient records of parliament; and in 1775 was appointed principal clerk in the record office in the Tower; from which, on the death of Sir John Shelly, he succeeded to the office of keeper of the records. He died in December 1803, and was the author of many curious papers in the volumes of the *Archæologia*; also of a work entitled *Origin and Progress of Writing*, as well hieroglyphic as elementary; which was first printed in 1784, 4to, and again in 1803.

ASTLEY (John), a native of Wem in Shropshire, though he studied painting under the same master with Sir Joshua Reynolds, is more memorable as a favorite of fortune, than as a limner. His best pictures are copies of the Bentivoglio's, Titian's Venus, &c. Lady Daniel, having sat to him for her picture, within a week after gave him the original, with the estate of Duckenfield, worth £5000 a year. He died in 1787.

ASTLEY (Philip), the founder of the royal amphitheatre near Westminster Bridge, was born at Newcastle-under-line in 1742, and bred a cabinet-maker. In 1759 he enlisted in the Light Horse, and served seven years in Germany, where he acquired the reputation of a good soldier. On his return home, he began to exhibit equestrian performances; and in 1780 erected a building which he called the amphitheatre riding house, for which he subsequently procured a license. In 1794 Mr. Astley went to the continent as a volunteer in the army. This campaign led to the publication of his *Descriptive and Historical Account of the places now the theatre of war in the Low Countries, with plans of fortifications: London, 1794, 8vo;* and *Remarks on the Profession and Duty of a Soldier*. Mr. Astley built amphitheatres at Dublin and at Paris, and the

Olympic Pavilion near the Strand. He closed an active and diversified life at Paris, October 20th, 1814, at the age of seventy-two. Another work of his is entitled *A System of Equestrian Education*, exhibiting the Beauties and Defects of the Horse, 1800, 4to.

ASTOMI, in anthropology, a people feigned to be without mouths. Pliny speaks of a nation of Astomi in India, who lived only by the smell or effluvia of bodies taken in by the nose!

ASTON (Sir Arthur), a commander in the service of Charles I. was at the head of the dragoons at the battle of Edgehill, and three times defeated the earl of Essex. He was successively governor of Reading and Oxford. He had the misfortune to break one of his legs in such a manner as to make amputation necessary; and, serving in Ireland after the death of the king, when Cromwell took Drogheda, where Aston was governor, his brains were beaten out with his wooden leg.

ASTON (Sir Thomas), of an ancient family in Cheshire, was created baronet in 1628, and appointed high sheriff of Cheshire in 1635. He raised a troop of horse for king Charles I., but was defeated and wounded in the vicinity of Nantwich in 1642. He was afterwards made prisoner, and carried to Stafford; and, while endeavouring to make his escape, a soldier struck him on the head, which, with other wounds he had received, brought on a fever, which ended in his death, in 1643. Sir Thomas was author of, 1. *A Remonstrance against Presbytery*, 1641, 4to; 2. *A Short Survey of the Presbyterian Discipline*; 3. *Brief Review of the Institution, Succession, and Jurisdiction of Bishops*.

ASTONE,	} Ang.-Sax. stunian, to stun. Old Fr. <i>estonne</i> , to amaze, to excite wonder, surprise; to strike as with thunder, startle, stupify, confound, benumb; to stony, or, as we say in modern phrase, to petrify. Astound is from the same root, and of a corresponding signification.
ASTON'Y.	
ASTON'YING,	
ASTON'IEDNESS,	
ASTON'ISH,	
ASTON'ISHEDLY,	
ASTON'ISHING.	
ASTON'ISHINGLY,	
ASTON'ISHMENT,	
ASTON'ED.	

But netheles how that it wende

He drad hym of his owne sonne

That maketh hym well the more *astone*.

Goucer. Con. A. book vi.

And with this word she fell to ground

Aswoune, and there she lay *astound*.

Id. ib. l. iv.

And anon all the puple seynge Jhesus was *astonyed* and thei dredden, and thei rennyngewritten him.

Wiclif. Mark, chap. ix.

Be *astonyshed* (O ye heauēns), be afrayde, and abashed at such a thinge, sayethe the Lord. For my people doue two euels. *Bible, 1539. Jeremy, c. ii.*

Her looks did so *astonish* me,

And set my heart a quaking;

Like stee that car'd, I was amaz'd,

And in a stranger taking.

Belchier, in Ellis, vol. iii.

These thoug'hts may startle well, but not *astound*, The virtuous mind; that ever walks, attended By a strong siding champion, conscience. *Milton.*

Now they lie

Groveling and prostrate on you lake of fire,

As we ere while, *astounded* and amaz'd,

No wonder, fall'n such a pernicious height.

Milton. Paradise Lost, b. i.

Princes, potentates,

Warriors, the flow'r of heaven, once yours, now lost,

If such *astonishment* as this can seize

Immortal spirits.

Id.

But all sate mute,

Pondering the danger with deep thoughts; and each

In other's countenance read his own dismay

Astonisht.

Id. b. ii.

As when some peasant in a bushy brake,

Has with unwary footing pressed a snake;

He starts aside, *astonish'd*, when he spies

His rising crest, blue neck, and rolling eyes.

Dryden's Virgil.

The palaces of Peru and Mexico were certainly mean and incommodious habitations, if compared to the houses of European monarchs; yet who could forbear to view them with *astonishment*, who remembered that they were built without the use of iron.

Johnson.

Whence many wearied e'er they had o'erpass'd

The middle stream (for they in vain have tried)

Again return'd *astounded* and aghast,

No one regardful look would ever backward cast.

Gilbert West.

A genius, universal as his theme,

Astonishing as chaos.

Thomson.

At first, heard solemn thro' the verge of heaven

The tempest growls; but as it nearer comes,

And rolls its awful burden on the wind,

The lightning's flash a larger curve, and more

The noise *astounds*.

Thomson's Seasons.

Unmanly dread invades

The French *astony'd*.

J. Philips.

Astonishment is that state of the soul in which all its motions are suspended, with some degree of horror.

Burke on the Sublime and Beautiful.

A character so exalted, so strenuous, so various, so authoritative, *astonished* a corrupt age, and the treasury trembled at the name of Pitt, through all her classes of venality.

Grattan's Character of Lord Chatham.

ASTORCHA, in botany, a name given by some botanists to the stoechas.

ASTORGA, an ancient city of Spain, in the kingdom of Leon, with a bishop's see, seated on the river Tuerto, and well fortified. It stands in a most agreeable plain, about 160 miles north-west of Madrid. It is now the chief place in a small marquisate, the castle of which it contains. In its territory lies the lake of Sanabria, through which the Tuerto passes with such rapidity as to agitate the whole surface.

ASTRÆA, in astronomy, a name of the sign Virgo, by others called Erigone, and sometimes Isis.

ASTRÆA, in mythology, the goddess of justice, and daughter of Jupiter by Themis, or, as others say, by Nemesis, the goddess of vengeance. The poets feign that Astræa quitted heaven to reside on earth, in the golden age; but, growing weary of the iniquities of mankind, she left the earth, and returned to heaven, where she commenced a constellation of stars, and from her orb still looks down on the ways of men.

ASTRAGAL, in architecture, a little round moulding, which in the orders surrounds the top of the shaft or body of the column. Its etymo-

logy is derived from its resemblance to the bone of the heel, called astragalos. It is also called the talon and tondino; it is used at the bottoms as well as the tops of columns, and on other occasions; it properly represents a ring, on whatever part of a column it is placed; and the original idea of it was that of a circle of iron put round the trunk of a tree used to support an edifice, to prevent its splitting. The astragal is often cut into beads and berries, and is used in the ornamented entablatures to separate the several faces of the architrave. See ARCHITECTURE.

ASTRAGAL, in gunnery, a round moulding encompassing a cannon, about half a foot from its mouth.

ASTRAGALOIDES, in botany, the phaca of Linnæus.

ASTRAGALOMANCY; from *αστραγαλος*, and *μαντικα*, divination; a species of divination performed by throwing small pieces, with marks corresponding to the letters of the alphabet; the accidental disposition of which formed the answer required. This kind of divination was practised in a temple of Hercules at Achaia.

ASTRAGALOTE, in natural history, a species of fossile alum, thus called from its resembling a talus, or ankle-bone; whence it is also denominated talare.

ASTRAGALUS, in anatomy, the bone of the heel. See ANATOMY.

ASTRAGALUS, in botany, milk-vetch, or liquorice vetch; a genus of the decandria order, and diadelphia class of plants; ranking in the natural method under the thirty-second order, papilionaceæ, the pod is gibbous and bilocular. Of this genus there are thirty-nine species. 1. *A. communis*, the common species, grows wild upon dry uncultivated places, and is often recommended by Mr. Anderson as proper food for cattle. 2. *A. tragacantha*, a thorny bush, growing in Crete, Asia, and Greece, which yields the gum tragacanth. This is of so strong a body, that a dram of it will give a pint of water the consistence of a syrup, which a whole ounce of gum Arabic is scarce sufficient to do. Hence its use for forming troches and the like purposes, in preference to the other gums.

ASTRAKHAN, a city and government of the Russian empire, on the shores of the Caspian, anciently an independent Tatarian sovereignty, but reduced to a Russian province by the Tzar Ivan Vasiliovich in 1554. It forms a distinct province, named after its principal city; having been separated from that of Caucasus, in which it was formerly included. It is bounded by the governments of Caucasus, Saratov, Orenburg, the country of the Kirgiz Tartars, the Caspian Sea, and the ci-devant Persian provinces of Daghistan and Lergistan; and contains 12,568 square geographical miles. The number of its inhabitants is from 300,000 to 400,000. Its extent from east to west is about 600 geographical miles, and from north to south about 520. The climate is rather warm, the thermometer rising in the summer to 158° (Fahrenheit); but the nights are cold, and the dew very copious. The ice is usually strong enough to bear at the end of November, and is not melted again till February.

This is followed by violent storms; but spring soon advances, the ground is covered with flowers, and the whole face of nature changed. The summer is remarkably dry. This government is separated from that of Kazan and the Kozaks of the Ural, by a barren branch of the Uralian chain, which stretches from north to south, and is the only line of hills in this province. The rest of the government is one continued level. The principal rivers, besides the Volga and Ural, are the Akhtuba, running parallel with the Volga, the Manich, the great and little Uzen, the Kuban, the Kuma, lost in the summer months in the sands, the Terek, the Malka, and the Sula. The air in the Steppes is said to be very unhealthy. At a distance from the stream the soil becomes salt and barren, and is covered with drifting sand. There are several salt lakes, such as the Bogdo, Basinskoe, Graznoe, Kobilikha, &c.

On the banks of the Volga rhubarb and liquorice are plentiful, and the extract from the root of the latter is prepared in considerable quantities in the city of Astrakhan. The sea-rose, found near the mouth of the Volga, is here considered as sacred and nutritious. Its flowers have a fragrant smell, and give an essential water of the scent of amber. The shrubs of the Steppes are cherries, sloes, dwarf almonds, and capers. Near the river there are the willow, alder, birch, ash, poplar, elm, and oak; the beech also on the Kuban; but no large woods. The fruit trees are Tatarian mulberries, cherries, apples, pears, plums, apricots, peaches, quinces, and vines; and on the latter there are also figs, almonds, wild olives, Spanish chestnuts, pomegranates, and Cornelian cherries (*Cornus mas*), which, when pickled, taste like olives. Silk, tobacco, and cotton are plentiful; and the gardens produce all the common roots and herbs. The pasturage is excellent, and much cattle is reared. Sea and rock-salt, natron, epsom-salt, salt-petre-earth, bitumen, and mineral pitch, are also an abundant source of wealth to Astrakhan.

The population of the province is composed of a great number of different nations; Russians, Kozaks, Tartars, Kalmuks, Indians, Persians, Armenians, &c. Generally the military, public officers, merchants, mechanics, and other citizens, are Russians. The garrisons on the Ural consist of Kozaks, derived from those of the Don, who choose their own officers, except their commander, the hetman, or ataman, who is appointed by the Russian government. The Tartars are, excepting a small number, nomad tribes, continually encamped, consisting of about 9000 families. The Kalmuks, about 12,000 families, are of the Derbet tribe, and encamp between the Volga, Don, and Kuma. There are also Armenians, Greeks, Georgians (Gruzinians), Bukharians, Khivinzians, and Hindoos, in considerable numbers, constantly inhabiting the city, to say nothing of the Europeans who are generally to be found there. Some colonies, established on the Terek and Kuma in 1781, cultivate grain, gardens, and vineyards, and produce a considerable quantity of silk. The number of their villages amounted to fifty-three in 1796.

ASTRAKHAN, the capital of the above government, (called originally *Илѣ Терханъ*, the

Giterchan, or Ginterchan, of the middle ages), is situated in E. long. $43^{\circ} 2' 15''$, N. lat. $46^{\circ} 21' 12''$, and is one of the most populous and important cities, ranking as the third town, perhaps, of the Russian empire. It contains nearly 70,000 inhabitants. It stands on a hill, in a long narrow island of the Volga, about thirty miles from its entrance into the Caspian, surrounded by swamps, which in spring are very unhealthy. The town itself, without including the suburbs, is from six to eight miles in circumference. The houses are built principally of brick and sand-stone. Here is an old Tatar castle, or kreml, and the Beloi-Gorod (white tower), built by the czar, Michael Feodorovich, now in ruins; a cathedral, archbishop's palace, public offices, main guard, arsenal, and powder magazine. Belgorod, which adjoins the kreml, on the same hill, is 2510 feet long, 1440 feet broad, and 7110 feet in circumference. The city has four gates, and some ruined walls. The streets are ill paved, and much exposed to inundations. Between the kreml and the canal, on the Volga, is the dock-yard, on the other side of which are the Tatarian and Armenian suburbs (slobods), and barracks for the troops. The exchange, where ships from the Caspian unlade and land their goods, is not far from St. Nicolas's Gate, and opposite to it is the haven for vessels coming down the river. Within the suburbs are about 100 vineyards, thirty of which belong to the crown; a school for the artillery, a bank, and a court of justice, in what was formerly the Troitzkoi convent; and, in the Belograd, the Spisso-preobrashenski convent, two parish churches, two hospitals, and a bazaar for the use of the Armenians and Hindoos.

The variety of nations and religions in Astrakhan is manifested by the number and difference of the places of worship. The total of them is fifty-seven: twenty-three Russian churches of the Greek communion; twenty-seven Tatarian mosques, churches, and temples; four Armenian, two Roman Catholic, one Lutheran, and one Hindoo temple. There is also a handsome hospital dedicated to St. Paul, and six monasteries; several dyeing-houses, brick-fields, tallow-candle manufactories, one iron-foundry, and looms for weaving linen, veils, and sashes. The morocco leather manufactured here is most esteemed, next to the Turkish; especially the red. There is also an establishment here for rearing silks-worms, and a botanic garden. European goods are brought either by water from Petersburg, or, on sledges, by land from Moscow, and are shipped across the Caspian, or conveyed to Mozdok, in Mount Caucasus. The merchants engaged in this trade employ 250 vessels of different tonnage. More than half of the whole trade carried on is in the hands of the Armenians. Many of the Russian merchants employ their vessels in trading voyages to Persia, Khiva, or Buchara, or carrying stores to Kizliar, and sell to the crown, to the towns on the Volga. The Hindoo merchants generally quit their native country at an early age, setting out with a small capital, which they soon increase by trade on the way from India and Persia; and make enormous profits by selling the Tatars of Astra-

khan have their goods on credit; so that the latter are always deeply in their debt.

The imports from Persia and Bukhara consist of raw silk, about 120,000 lbs. yearly, wool, dyed woollens, madder, galls, morocco leather, chintzes, dyed linens, silks, gauzes, small carpets, counterpanes, frankincense, bezoar, naphtha, rice, deer-skins, lamb-skins, Circassian cloth, tulups (pelisses), mountain-honey, tobacco, cotton gowns, Persian peas, dried fruits, almonds, figs, pomegranates, olives, oil, saffron, dried peaches, and spices. The exports consist almost entirely of foreign manufactures; such as velvet, cochineal, satin, plush, linen, and other woven articles, sugar, Russia-leather, iron, dyeing substances, glass, coral, steel and iron wares, metal utensils, wrought gold and silver, wax, soap, trinkets, alum, quick-silver, vitriol, sal-ammoniac, &c. Caravans often arrive by land at Astrakhan from Bukhara and Khiva. The Indian trade alone is from 6 to 700,000 roubles (£120 to 140,000) annually. The silk-manufactures are said to employ from 3 to 400,000 (£60 to 80,000). The supplies sent to the Caucasian lines along the Terek, from 4 to 500,000 (£100 to 120,000). The prices of all internal produce are low. Little is known concerning the origin of Astrakhan or of its condition before the thirteenth century, when William de Rubruguis found it a village without any fortifications; but, at the close of that century, it was a considerable emporium for the trade with India and China; and completely ruined by Timur. It was still a mere village when Josaphat Barbaro saw it in the fifteenth century; but Ambrosio Contareni, the Venetian ambassador, in the latter end of that century, found a considerable trade in rice and silk carried on there. The conquest of it, by the czar Ivan Vasilievich, in 1554, was therefore very advantageous to Russia, as it gave her the command not only of the Volga, but also of the Caspian, an advantage which she has not neglected to improve.

ASTRALISH, among miners, is the ore of gold in its first state.

ASTRANTIA, MASTERWORT, in botany, a genus of the digynia order, and the pentandria class of plants; ranking in the natural method under the forty-fifth order, umbellatæ. The involucrum is lanceolated, open, equal, and colored. The species are two: 1. *A. major*. 2. *A. minor*, both natives of the Alps, and possessing no remarkable properties.

ASTRAPÆA, in natural history, a name given by the ancients to a stone, since called, improperly, astrapia, and by some astrapias. It was of a blue, or blackish ore, with white variegations, running in the form of waves and clouds. Some specimens of the Persian lapis lazuli are of this kind, but they are rare.

ASTRARI, in writers of the middle age, the same with mansionarii, those who live in the house or family, at the time when a person dies.

ASTRARIUS HERES; from *astre*, old French, a hearth; is used in our old writers, where the ancestor, by conveyance, hath set his heirs apparent, and his family, in a house in his lifetime.

ASTRAY. According to Tooke, the past part of the Ang.-Sax. verb *stragan*, to stray, to scatter.

First every day, beseech thy God on knee,
So to direct thy stagg'ring steppes along;
That he which every secrete thought doth see,
May holde thee in, when thou wouldst goe *astray*.

Gascoigne.

You labour may
To lead *astray*,
The heart that constant shall remain,
And I the while
Will sit and smile,
To see you spend your time in vain.

George Wither, in Ellis, v. i.

And darkness and doubt are now flying away,
No longer I roam in conjecture forlorn.
So breaks on the traveller, faint, and *astray*,
The bright and the balmy effulgence of morn.

Beattie's Hermit.

ASTRICT, *v. & adj.* } *Astringo, astric-*
ASTRICTION, } *tum, astringere, to*
ASTRICTIVE, } *contract. To make*
ASTRINGE, } *strait or narrow, to*
ASTRINGENTLY, } *heighten or draw*
ASTRINGENT, *n. & adj.* } *close, to bind; op-*
posed to relax.

Tears are caused by a contraction of the spirits of the brain; which contraction, by consequence, *astringeth* the moisture of the brain, and thereby sendeth tears into the eyes. *Bacon.*

This virtue requireth an *astriction*; but such an *astriction*, as is not grateful to the body: for a pleasing *astriction* doth rather bind in the nerves, than expel them; and therefore such *astriction* is found in things of a harsh taste. *Id.*

The juice is very *astringent*, and therefore of slow motion. *Id. Natural History.*

What diminisheth sensible perspiration, increaseth the insensible; for that reason, a strengthening and *astringent* diet often conduceth to this purpose.

Arbutnot on Aliments.

The solid parts were to be relaxed or *astringed*, as they let the humours pass, either in too small or too great quantities. *Id.*

Lenitive substances are proper for dry atrabarian constitutions; who are subject to *astriction* of the belly, and the piles. *Id. on Diet.*

Acid, acrid, austere and bitter substances, by their *astringency*, create horror; that is, stimulate the fibres. *Id.*

Astringent medicines are binding, which act by the asperity of their particles; whereby they corrugate the membranes, and make them draw up closer. *Quincy.*

ASTRICTION, in law. See **THIRLAGE**.

ASTRICTION, in medicines, the operation of astringent medicines.

ASTRICUS LAPIS, in natural history, a kind of figured stone, broken or cut from the enastros, after the same manner as the trochiteæ, from the entrochi.

ASTRID'E, } On stride, on straddle. See
ASTRAD'E. } **STRIDE**, and **STRADDLE**.

To lay their native arms aside,

Their modesty; and ride *astride*. *Hudibras.*

I saw a place, where the Rhone is so straitened between two rocks, that a man may stand *astride* upon both at once. *Boyle.*

ASTRILD, in ornithology, a species of the loxia.

ASTRINGENTS, in the materia medica, substances distinguished by a rough austere taste,

and changing solutions of iron, especially those made in the vitriolic acid, into a dark purple or black color; such as galls, tormentil root, bistort root, balaustines, terra japonica, acacia, &c.

ASTROBOLISM; from *αστηρ*, a star, and *βαλλω*, to strike; the same with sphacelus; though properly applied to plants which are destroyed in the dog-days, as if blasted by that star.

ASTROCHITES, or **ASTROITES**. See **ASTERIA**.

ASTROGNOSIA; from *αστηρ*, star, and *γνωσκα*, I know; the art of knowing the fixed stars, their names, ranks, situations in the constellations, and the like. See **ASTRONOMY**.

ASTROLABE, } *Gr. αστηρ, a star, and*
ASTROLABRE, } *λαμβανω, I take.*
ASTROLABY.

The firste partye of this treatise shall rehearse the figures, and the membres of thine *astrolaby*, because that thou shalt have the greater knowyng of thyne owne instrument. *Chaucer. Astrolabie, f. 262. c. i.*

For I have ben toward the parties of Braban, and beholden the *astrolabre*, that the sterre that is clept the transmontayne, is 53 degrees highe.

Sir John Maundeville.

Liv'd Tycho now, struck with this ray which shone
More bright i' the morn, than others beam at noon,
He'd take his *astrolabe*, and seek out here
What new star 'twas did gild our hemisphere.

Dryden. On the Death of Lord Hastings.

ASTROLABE, among the ancients, was the same as our armillary sphere.

ASTROLABE, among the moderns, is used for a planisphere, or a stereographic projection of the sphere, either upon the plane of the equator, the eye being supposed to be in the pole of the world, or upon the plane of the meridian, at the time the eye is supposed in the point of the intersection of the equinoctial and horizon.

ASTRO'LOGY, } *Αστηρ, a star, and λογος,*
ASTRO'LOGER, } *a discourse; from λεγω, I*
ASTRO'LOGIAN, } *say. In Latin writers,*
ASTRO'LOGICK, } *astrology was synonymous*
ASTRO'LOGICALL, } *with, and more in use*
ASTRO'LOGICALLY. } *than, astronomy. This*
usage has been imitated by our elder writers.

On which was written, not in words,

But hieroglyphic mute of birds;

Many rare pithy saws concerning,

The worth of *astrologic* learning.

Butler's Hudibras, part i. can. 3.

A worthy *astrologer*, by perspective glasses, hath found in the stars many things unknown to the ancients. *Raleigh.*

Not unlike that, which *astrologers* call a conjunction of planets, of no very benign aspect the one to the other. *Wotton.*

Some seem a little *astrological*; as, when they warn us from places of malign influence. *Id.*

No *astrologick* wizard honour gains,

Who has not oft been banish'd, or in chains.

Dryden.

A happy genius is the gift of nature: it depends on the influence of the stars, say the *astrologers*; on the organs of the body, say the naturalists; it is the particular gift of heaven, say the divines, both Christians and heathens. *Id.*

Astrologers, that future fates foreshew. *Pope*

I never heard a finer satire against lawyers, than that of *astrologers*; when they pretend, by rules of art, to tell when a suit will end, and whether to the advantage of the plaintiff or defendant. *Swift.*

I know, the learned think of the art of *astrology*, that the stars do not force the actions or wills of men. *Id.*

Astrological prayers seem to me, to be built on as good reason, as the predictions. *Stillingfleet.*

The poetical fables are more ancient than the *astrological* influences; that were not known to the Greeks, till after Alexander the Great. *Bentley.*

The twelve houses of heaven, in the form which *astrologians* use. *Camden.*

ASTROLOGY; from *αστηρ*, a star, and *λογος*, discourse; was long considered as a science, by which future events could be foretold, from the aspects and positions of the heavenly bodies. In the literal sense of the term, astrology should signify no more than the doctrine or science of the stars; which was its original acceptation, and made the ancient astrology; though, in course of time, an alteration has arisen: that which the ancients called astrology, being afterwards termed *astronomy*. Astrology may be divided into two branches, natural and judicial.

ASTROLOGY, JUDICIAL OR JUDICIARY, is what we commonly call simple astrology, that which pretends to foretell moral events, i. e. such as have a dependence on the free will and agency of man; as if they were directed by the stars. This art, which owed its origin to the practices of knavery on credulity, is now universally exploded by the intelligent part of mankind. The professors of this kind of astrology maintain, 'That the heavens are one great volume or book, wherein God has written the history of the world; and in which every man may read his own fortune, and the transactions of his time.—The art, they say, had its rise with the science of astronomy. While the ancient Assyrians, whose serene unclouded sky favored their celestial observations, were intent on tracing the paths and periods of the heavenly bodies, they discovered a constant settled relation of analogy between them and things below; and hence were led to conclude these to be the parents, the destinies, so much talked of, which preside at our births, and dispose of our future fate. The laws therefore of this relation being ascertained by a series of observations, and the share each planet has therein; by knowing the precise time of any person's nativity, they were enabled, from their knowledge in astronomy, to erect a scheme or horoscope of the situations of the planets, at that point of time; and hence, by considering their degrees of power and influence, and how each was either strengthened or tempered by some other, to compute what must be the result.' Such are the arguments of the astrologers in favor of their science. The chief province now remaining to the professors of this art, is the making of calendars or Almanacks; and the prodigious sale of Moore's almanack, in this country, is no small proof of the popular belief in this subject.

Judicial astrology is commonly said to have been invented in Chaldea, and thence transmitted to the Egyptians, Greeks, and Romans; though some will have it of Egyptian origin, and ascribe the invention to Ham. But it is to the

Arabs we owe it. At Rome the people were so infatuated with it, that the astrologers, or, as they were then called, the mathematicians, maintained their ground notwithstanding the edicts of the emperors to expel them out of the city. Domitian, in spite of his hostility to this art, trembled at its denunciations. They prophesied the year, the hour, and the manner of his death; and agreed with his father in foretelling, that he should perish, not by poison, but by the dagger. On the evening of his assassination he spoke of the entrance of the moon into Aquarius on the morrow. 'Aquarius,' he said, 'shall no longer be a watery, but a bloody sign; for a deed shall there be done, which shall be the talk of all mankind.' The dreaded hour of eleven approached. His attendants told him it was passed, and he admitted the conspirators and fell. *Suet. in Domit. 16.*

The Brahmins, who introduced and practised this art among the Indians, have hereby made themselves the arbiters of good and evil hours, which gives them great authority; they are consulted as oracles; and have taken care never to sell their answers but at good rates. The same superstition has prevailed in more modern ages and nations. The French historians remark, that in the time of Catherine de Medicis, astrology was so much in vogue, that the most inconsiderable thing was not to be done without consulting the stars. And in the reign of king Henry III. and IV. of France, the predictions of astrologers were the common theme of the court conversation. This predominant humor in that court was well rallied by Barclay, in his *Argenis*, on occasion of an astrologer, who had undertaken to instruct king Henry in the event of a war then threatened by the faction of the Guises.

Little is known of the early history of astrology in England. Bede and Alcuin, among our Anglo-Saxon ancestors, were addicted to its study; and Roger Bacon could not escape the imputation of the art. His imprisonment was owing, it is well known, to his being supposed skilful in it. But it was the period of the Stuarts which must be considered as the acme of astrology among us. Then Lilly drank the doctrine of the magical circle, and the invocation of spirits from the *Ars Notoria* of Cornelius Agrippa; used the form of prayer prescribed therein to the angel Salomoncus; and entertained among his familiar acquaintance the guardian spirits of England, Sammael and Malchidael. *Merlin Anglicus, 1647.* The author of *Waverley* has made ample use of this promising character in his tales relative to this period.

The signs of astrology were primarily divided thus: the six first were called northern, and commanding; the six last southern, and obeying. Next they were distributed into four triplicities, (so called because three belonged to each), fiery, earthy, airy, and watery. Of these the fiery and airy were said to be masculine, the earthy and watery, feminine. The planets by their motion made several aspects. See **ASPECTS**. The remaining influential parts of the heaven were two, Dragon's Head and Tail, that, is the nodes in which the ecliptic is intersected by the orbits of the planets; and the Part of For-

tune, that is the distance of the moon's plane from the sun, added to the degrees of the ascendant.

The influences of the heavenly bodies being determined, it remained only, in each separate case, to observe their positions at some required moment; for upon this, and their aspect to each other, the resolution of any question depended. For this purpose the whole circle of the heavens was distributed into twelve parts or houses, by great circles drawn through the intersection of the horizon and meridian, and cutting the equator in so many equal parts. The first house was placed directly east, and the remainder were counted round in order proceeding to the south according to the motion of the planets. *To each of these houses was assigned some peculiar government, according to the scheme below.

The remainder of the art consisted in accurately filling the scheme by an observation, and then framing from it an oracular response.

At the revolution astrology declined; and notwithstanding the labors of the immortal Partridge then, and those of Ebenezer Sibley, which in our own days fill two 4to. volumes, the art may now be considered as exploded.

ASTROLOGY, NATURAL, is the predicting of natural effects from natural causes; as, the changes of weather, winds, storms, hurricanes, thunder, floods, earthquakes, &c. This art properly belongs to physiology, or natural philosophy; and is only to be deduced a posteriori, from phenomena and observations.

ASTROLOMA, in botany; from *αστρον*, a star, and *λωμα*, a fringe, alluding to the five tufts of hair which form a star, near the bottom of the tube of the flower, internally. Brown Prodr. Nov. Holl. v. i. 538. Class and order, pentandria monogynia. Nat. ord. Ericæ Juss. Epacridæ, brown.

Gen. ch. CAL. perianth inferior, permanent, double; inner of five elliptic-lanceolate, acute, equal, erect leaves; outer of four or more, much shorter, concave, imbricated scales: COR. of one petal, tubular; tube twice the length of the calyx,

inflated, furnished on the inside, near the base, with five tufts of soft hairs; limb in five deep, spreading, lanceolate, acute, hairy segments, shorter than the tube. Nectary a cup-shaped undivided gland, surrounding the base of the germen: STAM. filaments five, linear, inserted into the tube, and enclosed within it; anthers oblong, in the mouth of the tube: PRST. Germen superior, roundish, of five cells; style capillary, the length of the tube; stigma 'globose, densely downy.' PERIC. drupa globular, slightly juicy: SEED, nut of five cells, hard and solid, not bursting, with a pendulous oblong kernel in each cell.

Ess. ch.: outer calyx of several imbricated leaves: corolla tubular: tube swelling, twice as long as the calyx, with five internal tufts of hair at the base: tube shorter, spreading, bearded: filaments linear, within the tube: drupa almost dry, of five cells. This genus is closely related to *stenanthera*, as well as to *melichrus*. We might perhaps unite them all to *stypelia*.

Astroloma consists of shrubs, of humble stature, for the most part decumbent: leaves scattered, often ciliated: flowers axillary, erect. There are six species: 1. *A. humifusum*, diffuse *astroloma*; stem prostrate, much branched. Found in various parts of New Holland, on the south-west coast, as well as at Port Jackson and in Van Diemen's island. The remaining five species have all been found in the southern part of New Holland, by Mr. Brown, and apparently by no other botanist. We give their names from his work: 2. *A. prostratum*, prostrate *astroloma*; 3. *A. denticulatum*, toothed *astroloma*; 4. *A. pallidum*, pale *astroloma*; 5. *A. compactum*, compact *astroloma*; 6. *A. tectum*, upright *astroloma*.

ASTROLUS, in natural history, a name given by authors to a white and splendid stone, small in size, and of a roundish figure, resembling the eyes of fishes.

ASTROMETEOROLOGIA, the art of foretelling the weather, and its changes, from the aspects and configurations of the moon and planets. It is a species of astrology, sometimes called meteorological astrology.

ASTRONIUM, in botany, a genus of the pentandria order, and the diccia class of plants. The male calyx consists of five leaves, and the corolla is quinquepetalous. Of the female the calyx and corolla are the same as in the male; the styli are three, and the seed is single. There is but one species, viz. *A. graveolens*, a native of Jamaica.

ASTRONOMICAL CALENDAR, an instrument engraved on copper plates, printed on paper, and pasted on a board, with a brass slider carrying a hair: it shows by inspection the sun's meridian altitude, right ascension, declination, rising, setting, amplitude, &c. to a greater degree of exactness than the common globes.

ASTRONOMICAL PLACE of a star, or planet, is its longitude, or place in the ecliptic, reckoned from the beginning of Aries in consequentia, or according to the natural order of the signs.

ASTRONOMICALS, a name used by some writers for sexagesimal fractions; on account of their use in astronomical calculations.

A S T R O N O M Y.

ASTRO'NOMY, }
 ASTRO'NOMICK, }
 ASTRONOM'ICAL, } From *αστηρ*, a star,
 ASTRONOMICALLY, } and *νομος*, a law.
 ASTRON'OMER, }
 ASTRON'OMIZE. }

Images *astronomically* framed under certain constellations to preserve from several inconveniences, as under the sign of the Lion the figure of a lion made in gold, against melancholic fancies, dropsie, plague, fevers. *Bp. Hall's Cases of Conscience.*

Our forefathers, marking certain mutations to happen in the sun's progress through the zodiack, they registrate and set them down in their *astronomical canons*. *Brown's Vulgar Errors.*

The old ascetick Christians found a paradise in a desert, and with little converse on earth, held a conversation in heaven; thus they *astronomized* in caves; and though they beheld not the stars, had the glory of heaven before them. *Brown. Chris. Mor. ii. 9.*

Astronomers no longer doubt of the motion of the planets about the sun. *Locke.*

The old and new *astronomers* in vain
 Attempt the heav'nly motions to explain.

Blackmore.

Can he not pass an *astronomick* line,
 Or dreads the sun th' imaginary sign;

That he should ne'er advance, to either pole? *Id.*

To this must be added the understanding of the globes, and the principles of geometry and *astronomy*. *Cowley.*

INTRODUCTION.

SECT. I. ETYMOLOGY AND DEFINITION OF ASTRONOMY.

1. *ASTRONOMY*, a mixed mathematical science, teaching the knowledge of the celestial bodies; their magnitudes, distances, motions, revolutions, and eclipses; and it comprehends also a knowledge of the natural causes on which all celestial phenomena depend. Hence it is as much a branch of physics as of mathematics, and comprehends the theory of the universe.

SECT. II. HISTORY OF ASTRONOMY.

2. AS *Astronomy* is the most sublime of all the sciences, so it is also the most useful, the most ancient, and, we may add, the most perfect. How can it be otherwise than sublime, when its object is the study of that theatre which our merciful Creator has vouchsafed to establish as an unerring testimony of his existence and his power. Whoever we turn we perceive immensity of operation, guided by the strictest regularity. We find revolutions, intricate and complex, but resolving themselves, by laws irrevocably fixed, into paths the most simple, and the most capable of suffering an increase of numbers without confusion. In another point of view it is sublime; the contemplation of its discoveries and its usefulness would convince the dreary-minded bigot, who sneers at human reason and its efforts, of the amazing extent to which that noblest gift of God to man can be extended. *Astronomy* is the proudest triumph of philosophy and of human reason. Its superior usefulness when compared with the other sciences can never be opposed by any thing that is conducted through

unknown seas with safety; and the merchant transports the produce or the surplus of one nation to increase the comforts or relieve the wants of another; in short, it affords the means of intercourse to all the inhabitants of the globe. If, from the folly of mankind, it has sometimes been compelled to effect the transportation of animosity and destruction, it has more frequently assisted the dissemination of arts, civilisation, and happiness. That it is the oldest science we shall more clearly ascertain when we trace, as we shall soon do, its history through the most ancient, and its improvements through the most modern, nations. If then *astronomy* is possessed of the highest antiquity, the greatest usefulness, and the utmost sublimity, it is an object of the most transcendent worth that can occupy the attention of the human mind.

3. None of the sciences appear to be of higher antiquity than *astronomy*. From the account given by Moses of the creation of the celestial luminaries, it appears extremely probable that our first progenitor received some knowledge of their nature and uses from his Almighty Creator himself. The Jewish rabbins have adopted this opinion: and, indeed, it is natural to think that no visible objects would more readily excite the curiosity, or appear more worthy of the contemplation of Adam in a state of innocence, than the celestial bodies.

4. Consistently with this, Josephus ascribes to Seth and his posterity a considerable degree of astronomical knowledge. He speaks of two pillars, the one of stone and the other of brick, called the pillars of Seth, upon which were engraved the principles of the science; and he says that the former was still entire in his time. But, be this as it may, it is evident that the great length of the antediluvian lives would afford such excellent opportunities for observing the heavenly bodies, that we cannot but suppose that the science of *astronomy* must have been considerably advanced before the flood. Josephus says, that longevity was bestowed upon them for the very purpose of cultivating the sciences of geometry and *astronomy*; observing, that the latter could not be learned in less than 600 years; 'for that period (he adds) is the grand year.'

5. By this remarkable expression is probably meant the period in which the sun and moon come again into the same situation in which they were at the beginning of it, with regard to the nodes, apogee of the moon, &c. 'This period (says Cassini), of which we find no intimation in any monument of any other nation, is the finest period that ever was invented; for it brings out the solar year more exactly than that of Hipparchus and Ptolemy; and the lunar month within about one minute of what is determined by modern astronomers.' If the antediluvians had such a period of 600 years they must have known the motions of the sun and moon more exactly than their descendants knew them for many ages after the flood. That remarkable expression in the book of Job, in which

the Deity is spoken of as the being who 'maketh Arcturus, Orion, and the chambers of the south,' is too striking to be overlooked.

6. Indeed, besides the motives of mere curiosity, which of themselves may be supposed to have excited people to a contemplation of the glorious celestial canopy, it is easy to see that some parts of the science answer such essential purposes to mankind that they could not long be dispensed with. And it has been remarked that traces of this science, in different degrees of improvement, have been found among all nations.

7. Upon the building of the Tower of Babel, it is supposed that Noah retired with his children, born after the flood, to the north-eastern part of Asia, where his descendants peopled the vast empire of China. It is said also that the Jesuit missionaries have found traditional accounts among the Chinese of their having been taught this science by their first emperor Fo-hi, who is supposed to be the same with Noah; and Kempfer asserts that Fo-hi discovered the motions of the heavens, divided time into years and months, and invented the twelve signs, into which they divide the zodiac, and which they distinguish by the following names: 1. the mouse; 2. the ox or cow; 3. the tiger; 4. the hare; 5. the dragon; 6. the serpent; 7. the horse; 8. the sheep; 9. the monkey; 10. the cock or hen; 11. the dog; and 12. the boar. They divide the heavens into twenty-eight constellations, or classes of stars, allotting four to each of the seven planets; so that the year always begins with the same planet; and their constellations answer to the twenty-eight lunar mansions used by the Arabian astronomers.

8. They do not, however, mark these constellations with the figures of animals, like most other nations, but by connecting the stars by straight lines, and denoting the stars themselves by small circles: so, for instance, the great bear would be marked as represented in plate IV. fig. 9.

9. The Chinese themselves have many records of the high antiquity of their astronomy; though not without suspicion of great mistakes. They ascribe the discovery of the pole-star, the invention of the sphere, and mariners' compass, &c. to their emperor Hong-Ti, the grandson of Noah. But on more certain authority it is asserted by Gaubil that, at least 120 years before Christ, the Chinese had determined by observation the number and extent of their constellations as they now stand; the situation of the fixed stars with respect to the equinoctial and solstitial points; and the obliquity of the ecliptic, with the theory of eclipses; and that they were, long before that, acquainted with the true length of the solar year, the method of observing meridian altitudes of the sun by the shadow of a gnomon, and of deducing from thence his declination and the height of the pole.

10. The same missionary also says that the Chinese have yet remaining some books of astronomy which were written about 200 years before Christ; from which it appears that the Chinese knew the daily motion of the sun and moon, and the time of the revolutions of the planets, many years before that period. Du

Halde informs us that Tcheou-cong, the most skilful astronomer that ever China produced lived more than a thousand years before Christ, that he passed whole nights in observing the celestial bodies and arranging them into constellations, &c. At present, however, the state of astronomy is but very low in that country, although it is cultivated at Pekin by public authority, as in most of the capital cities of Europe. This is ascribed, by Dr. Long, to a barbarous decree of one of their emperors, to burn all the books in the empire excepting such as related to agriculture and medicine.

11. Astronomy, according to Porphyry, must have been of very ancient standing in the East. He informs us that when Babylon was taken by Alexander there were brought from thence celestial observations for the space of 1903 years; which therefore must have commenced within 115 years after the flood, or within fifteen years after the building of Babel. Epigenes, according to Pliny, affirmed that the Babylonians had observations of 720 years engraven on bricks.

12. Achilles Tattius ascribes the invention of astronomy to the Egyptians; and adds that their knowledge of that science was engraven on pillars, and by that means transmitted to posterity. Bailly, in his elaborate History of Ancient and Modern Astronomy, endeavours to trace the origin of this science among the Chaldeans, Egyptians, Persians, Indians, and Chinese, to a very early period; and he maintains that it was cultivated in Egypt and Chaldea 2800 years before Christ; in Persia, 3209; in India, 3101; and in China, 2952 years before that era. He also apprehends that astronomy had been studied even long before this distant period, and that we are only to date its revival from thence.

13. M. Bailly, in investigating the antiquity and progress of astronomy among the Indians, examines and compares four sets of astronomical tables of the Indian philosophers, viz. that of the Siamese, explained by M. Cassini in 1689; that brought from India by M. le Gentil, of the Academy of Sciences; and two other manuscript tables, found among the papers of M. de Lisle: all of which agree together, and refer to the meridian of Benares. It appears that the fundamental epoch of the Indian astronomy is a conjunction of the sun and moon which took place at the distance of years 3102 A. A. C. And M. Bailly computes that such a conjunction really then happened.

14. He farther observes that at present the Indians calculate eclipses from observations made 5000 years ago; the accuracy of which, with regard to the solar motion, far exceeds that of the best Grecian astronomers. The lunar motions have been computed from the space through which that luminary passes in 1,600,984 days. They also use the cycle of nineteen years, the same as that ascribed by the Greeks to Meton. Their theory of the planets is better than that of Ptolemy, as they do not suppose the earth to be the centre of the celestial motions, and believe that Venus and Mercury move round the sun. Their astronomy also agrees with the most modern discoveries, with regard to the obliquity of the ecliptic and the acceleration of the

equinoctial points, &c. The inhabitants of Japan, of Siam, and of the Mogul's empire, have also been acquainted with astronomy from time immemorial; and the celebrated observatory at Benares is a monument both of the ingenuity of the Hindoos, and of their skill in that science.

15. In the Transactions of the Royal Society of Edinburgh, vol. ii, professor Playfair has given a learned and ingenious dissertation on the astronomy of the Brahmins, in which the great accuracy and high antiquity of the science among them is rendered extremely probable. It appears that their tables and rules of computation have peculiar reference to an epoch, and to observations 3000 or 4000 years A. C. It appears, too, that very considerable mathematical knowledge had been employed in their precepts and calculations. But amongst all these precepts and those calculations, perhaps none will strike the mind of the reader with greater force than the following, from which we shall find, without plucking a leaf from the never-fading laurels of Sir Isaac Newton, that the principle which he developed to the western world, was discovered by the philosophers of the eastern, thousands of years before he existed: of the truth of this the following remarkable passage, translated by Sir William Jones, from the poem of Shirin and Ferhad: 'there is,' says the author of that poem, 'a strong propensity which dances through every atom and attracts the minutest particle to some peculiar object; from such propensity arises every motion perceived in heavenly or terrestrial bodies. It is a disposition to be attracted which taught hard steel to rush from its place and rivet itself on the magnet; it is the same disposition which impels the light straw to attach itself firmly on amber.'

16. We shall conclude this part of the history of Asiatic discoveries in the words of professor Playfair: 'That observations made in India, when all Europe was barbarous or uninhabited, and investigations into the most subtle effects of gravitation made in Europe near five thousand years afterwards, should thus come in mutual support of one another, is perhaps the most striking example of the progress and vicissitudes of science, which the history of mankind has yet exhibited.'

17. It appears too, that astronomy was not unknown to the Americans; though in their division of time they made use only of the solar and not of the lunar motions. The Mexicans, in particular, had a strange predilection for the number thirteen: their shortest periods consisted of thirteen days; their cycle of thirteen months, each containing twenty days; and their epoch of four periods of thirteen years each. This excessive veneration for the number thirteen arose, according to Siguenza, from its being the number of their greater gods. Clavigero also asserts it as a fact, that having discovered the excess of a few hours in the solar above the lunar year, they made use of intercalary days to bring them to an equality, as was done by Julius Cæsar in the Roman calendar—but with this difference, that instead of one day every four years, they interposed thirteen days every fifty-two years.

18. Among the ancients we find the name of Chaldean used often for astronomer or astrologer. Indeed both these nations pretended to a very high antiquity, and claimed the honor of producing the first cultivators of this science. The Chaldeans boasted of their temple or tower of Belus, and of Zoroaster, whom they placed 5000 years before the destruction of Troy; while the Egyptians boasted of their colleges of priests, where astronomy was taught, and of the monument of Osymandias, in which, it is said, there was a golden circle of 365 cubits in circumference, and one cubit thick, divided into 365 equal parts, according to the days of the year, &c. It is indeed evident that both Chaldea and Egypt were countries very proper for astronomical observations, on account of the extended flatness of the country, and the purity and serenity of the air. The tower of Belus, or of Babel itself, was probably an astronomical observatory; and the pyramids of Egypt, whatever they were originally designed for, might perhaps answer the same purpose; at least they show the skill of this people in practical astronomy, as they are all placed with their four fronts exactly facing the cardinal points of the compass.

19. The Chaldeans began to make observations soon after the confusion of languages, as appears from the observations found by Alexander on the taking of Babylon; and it is probable they began much earlier. They determined, with tolerable exactness, the length both of a periodical and synodical month. They discovered that the motion of the moon was not uniform; and they even attempted to assign those parts of the orbit in which the motion is quicker or slower. We are assured by Ptolemy that they were not unacquainted with the motion of the moon's apogee and nodes, the latter of which they supposed made a complete revolution in $6585\frac{1}{2}$ days, or a little more than eighteen years, and contained 223 complete lunations, which period is called the Chaldean Saros.

20. Ptolemy also gives us from Hipparchus several observations of lunar eclipses made at Babylon above 720 years A. A. C.; and Aristotle informs us that they had many occultations of the planets and fixed stars by the moon; a circumstance which led them to conceive that eclipses of the sun were to be attributed to the same cause. They had also no inconsiderable share in arranging the stars into constellations, and the comets did not escape their observation. Dialling was also practised among them long before the Greeks were acquainted with that science.

21. The Egyptians were much of the same standing in astronomy with the Chaldeans. Herodotus ascribes their knowledge in the science to Sesostris; but probably not the same whom Newton makes contemporary with Solomon, as they were acquainted with astronomy at least many hundred years before that era. We learn from the testimony of some ancient authors, that they believed the figure of the earth was spherical; that the moon was eclipsed by passing through the earth's shadow, though it does not certainly appear that they had any knowledge of the true system of the universe; that they attempted to measure the magnitude of the earth and sun,

though their methods of ascertaining the latter were very erroneous; and that they even pretended to foretel the appearance of comets, as well as earthquakes and inundations. This science, however, gradually decayed, and in the time of Augustus it was entirely extinct among them.

22. Astronomy passed from Chaldea and Egypt to the Phœnicians, and was applied by that commercial people to the purposes of navigation; and they, in consequence, became masters of the sea, and of almost all the commerce in the world. The Greeks, it is probable, derived their astronomical knowledge chiefly from the Egyptians and Phœnicians, by means of several of their countrymen who visited these nations for the purpose of learning the different sciences. Newton supposes that the division into constellations was made about the time of the Argonautic expedition; but it is probable that most of them were of a much older date, and derived from other nations, though clothed in fables of their own invention.

23. The fable of Atlas supporting the heavens upon his shoulders, shows that some Mauritanian monarch of that name had made considerable advances in astronomical knowledge; and his discoveries had probably been communicated to the Greeks. Several of the constellations are mentioned by Hesiod and Homer, who lived about A. A. C. 870. Their knowledge in this science however, was greatly improved by Thales the Milesian, and other Greeks, who travelled into Egypt, and brought from thence the chief principles of the science. Thales was born about A. A. C. 640, and he was the first among the Greeks who observed the stars, the solstices, and predicted the eclipses of the sun and moon.

24. The science was farther cultivated and extended by his successors Anaximander, Anaximenes, and Anaxagoras; but especially by Pythagoras, who, about A. A. C. 577, brought from Egypt the learning of these people, taught it in Greece and Italy, and founded the sect of the Pythagoreans. He taught that the sun was in the centre of the universe; that the earth was round; that there were antipodes; that the moon reflected the rays of the sun, and was inhabited like the earth; that comets were a kind of wandering stars, disappearing in the further parts of their orbits; that the white color of the milky way was owing to the united brightness of a great multitude of small stars; and he supposed that the distances of the moon and planets from the earth, were in certain harmonic proportions to one another.

25. Philolaus, a Pythagorean, who flourished about A. A. C. 450, and asserted the diurnal motion of the earth on its own axis, was taught by Hicetas, a Syracusan. About the same time Meton and Euctemon flourished at Athens, where they observed the summer solstice, A. A. C. 432, with the risings and settings of the stars, and what seasons they answered to. Meton also invented the cycle of nineteen years, which still bears his name.

26. Eudoxus, of Cnidos, lived about A. A. C. 370, and was one of the most skilful astronomers and geometers of antiquity, and the supposed inventor of many of the propositions in Euclid's

Elements. He introduced geometry into the science of astronomy, and travelled into Asia, Africa, Sicily, and Italy, to improve it: and we are informed by Pliny, that he determined the annual year to contain 365 days 6 hours, and also the periodical time of the planets, and made other important discoveries and observations. Calippus flourished soon after Eudoxus, and his celestial sphere is mentioned by Aristotle; but he is better known by a period of seventy-six years which he invented, containing four corrected Metonic periods, and which commenced at the summer solstice, A. A. C. 330. About this time the knowledge of the Pythagorean system was carried into Italy, Gaul, and Egypt, by certain colonies of Greeks.

27. Vitruvius, however, represents the introduction of astronomy into Greece, in a manner somewhat different. He maintains that Berossus, a Babylonian, brought it immediately from Babylon itself, and opened an astronomical school in the isle of Cos. And Pliny says, that, in consideration of his wonderful predictions, the Athenians erected a statue to him in the gymnasium, with a gilded tongue. But if this Berossus be the same with the author of the Chaldaic histories, he must have lived before Alexander. About this time, or rather earlier, the Greeks having begun to plant colonies in Italy, Gaul, and Egypt, became acquainted with the Pythagorean system, and the notions of the ancient druids concerning astronomy. Julius Cæsar informs us that the latter were skilled in this science; and that the Gauls in general were able sailors, which they could not be without a competent knowledge of astronomy; and it is related of Pytheas, who lived at Marseilles in the time of Alexander the Great, that he observed the altitude of the sun at the summer solstices by means of a gnomon. He is also said to have travelled as far as Thule to settle the climates.

28. After Alexander's death the sciences flourished chiefly in Egypt, under the auspices of Ptolemy Philadelphus, and his successors. He founded a school there, which continued till the invasion of the Saracens, A. A. C. 650. From the founding of that school, the science of astronomy advanced considerably. Aristarchus, about A. A. C. 270, strenuously asserted the Pythagorean system, and gave a method of determining the sun's distance by the dichotomy of the moon.—Eratosthenes, who was born at Cyrene A. A. C. 271, measured the circumference of the earth by a gnomon; and being invited to Alexandria, from Athens, by Ptolemy Euergetes, and made keeper of the royal library there, he set up for that prince those armillary spheres, which Hipparchus and Ptolemy the astronomer afterwards employed so successfully in observing the heavens. He also determined the distance between the tropics to be $\frac{1}{4}$ of the whole meridian circle, which makes the obliquity of the ecliptic in his time to be $23^{\circ} 51' \frac{1}{4}$.

29. The celebrated Archimedes, too, cultivated astronomy, as well as geometry and mechanics, determined the distances of the planets from one another; and constructed a kind of planetarium or orrery, to represent the phenomena and motions of the heavenly bodies.

30. Not to mention many others of the ancients who cultivated astronomy, Hipparchus, who flourished about A. A. C. 140, was the first who applied himself to the study of every branch of that science. Ptolemy says he made great improvements in it; he discovered that the orbits of the planets are eccentric, that the moon moved slower in her apogee than in her perigee, and that there was a motion of anticipation of the moon's nodes: he constructed tables of the motions of the sun and moon, collected accounts of such eclipses, &c. as had been made by the Egyptians and Chaldeans, and calculated all that were to happen for 600 years: he discovered that the fixed stars changed their places, having a slow motion of their own from west to east; he corrected the Calippic period, and pointed out some errors in Eratosthenes's method for measuring the circumference of the earth; he computed the sun's distance more accurately than his predecessors: but his best work is a catalogue of the fixed stars, to the number of 1022, with their longitudes, latitudes, and apparent magnitudes; which, with most of his other observations, are preserved by Ptolemy in his *Almagest*.

31. From the time of Hipparchus, till that of Ptolemy, little progress was made in astronomy. He was born at Pelusium, in Egypt, in the first century, and made the greatest part of his observations at the celebrated school of Alexandria in that country. Profiting by those of Hipparchus, and other ancient astronomers, he formed a system of his own, which, though erroneous, was implicitly followed for many ages by all nations. He compiled a great work, called the *Almagest*, which contained the observations and collections of his predecessors in astronomy. This work was preserved from the conflagration of the Alexandrian library by the Saracens, and translated into Arabic, A. D. 827, and into Latin in 1230. The Greek original was not known in Europe till the beginning of the fifteenth century, when it was brought from Constantinople, then taken by the Turks, by a monk of Trapezond, named George, who translated it into Latin; and various other editions have been since made.

32. From A. D. 800, till the beginning of the fourteenth century, the western parts of Europe were immersed in gross ignorance, while the Arabians, profiting by the books they had preserved from the wreck of the Alexandrian library, cultivated and improved all the sciences, and particularly that of astronomy, in which they had many able professors and authors. The caliph Al Mansur first introduced a taste for the sciences into his empire. His grandson, Al Mamun, who ascended the throne in 811, was a great encourager and patron of the sciences, especially of astronomy. Having ordered proper instruments to be made many observations; determined the obliquity of the ecliptic to be $23^{\circ} 35'$; and ascertained the arc of a degree of the circle of the earth was measured a second time in the plain of Sinjar, on the border of the Red Sea.

33. About this time Albatignus wrote elements of astronomy; and Albatignus, who flourished about the year 830, greatly reformed it, by comparing his own observations with those of Ptolemy. Hence he computed the motion of the

sun's apogee from Ptolemy's time to his own, settled the precession of the equinoxes at one degree in seventy years; and fixed the obliquity of the ecliptic at $23^{\circ} 35'$. The tables which he composed for the meridian of Aracta, were long esteemed by the Arabians.

34. After this, though the Saracens had many eminent astronomers, several centuries elapsed without producing any very valuable observations, excepting those of some eclipses observed by Ebn Younis, astronomer to the caliph of Egypt, by means of which the quantity of the moon's acceleration since that time may be determined. Other eminent Arabic astronomers were Arzachel, a Moor of Spain, who observed the obliquity of the ecliptic, and improved trigonometry by constructing tables of sines, instead of chords of arches, dividing the diameter into 300 equal parts. Alhazen his contemporary, wrote upon the twilight, the height of the clouds, the phenomenon of the horizontal moon, and first showed the importance of the theory of refractions in astronomy.

35. Ulug Beg, grandson of the celebrated Tamerlane, the Tartarian prince, a great proficient in practical astronomy, had very large instruments, particularly a quadrant of about 180 feet high, with which he made good observations. From these he determined the latitude of Samarcand, his capital, to be $39^{\circ} 27' 23''$; and composed astronomical tables for the meridian of the same so exact, that they differ very little from those constructed afterwards by Tycho Brahe.—His principal work was his catalogue of the fixed stars, made from his own observations in the year 1437.

36. At this period, almost all Europe was immersed in ignorance; which began to be dispelled by the settlement of the Moors in Spain. The emperor Frederic II. about 1230, also began to encourage learning; restoring some decayed universities, founding a new one in Vienna; and causing the works of Aristotle and Ptolemy's *Almagest*, to be translated into Latin. Two years after this, John de Sacro Bosco, that is of Halifax, compiled from Ptolemy, Albatignus, Alferganus, and other Arabic astronomers, his work, *De Sphæra*, which was held in the greatest estimation for 300 years after, and was honored with commentaries by Clavius and other learned men.

37. In 1240 Alphonso, king of Castile, not only cultivated astronomy himself but greatly encouraged others; and by the assistance of several learned men corrected the tables of Ptolemy, and composed those which were denominated from him the Alphon sine tables. About the same time Roger Bacon, an English monk, wrote several tracts relative to astronomy, particularly of the lunar aspects, the solar rays, and the places of the fixed stars; and about 1270 Vitello, a Polander, composed a treatise on optics, in which he showed the use of refractions in astronomy.

38. Till the time of Purbach, who was born in 1423, little farther improvement was made in this science. He composed new tables of sines for every ten minutes, making the radius sixty with four cyphers annexed. He constructed spheres and globes, and wrote several astronomical tracts, as a commentary on Ptolemy's *Alma-*

gest; some treatises on arithmetic and dialling, with tables for various climates; new tables of the fixed stars reduced to the middle of that century; and he corrected the tables of the planets, making new equations to them where the Alphonsine tables were erroneous. In his solar tables, he placed the sun's apogee in the beginning of Cancer; but retained the obliquity of the ecliptic $23^{\circ} 33\frac{1}{2}'$, as determined by the latest observations. He also observed some eclipses, made new tables for computing them, and had just finished a theory of the planets, when he died in 1462, being only thirty-nine years of age.

39. Purbach was succeeded in these labors by his pupil and friend, John Muller, commonly called Regiomontanus, who completed the epitome of Ptolemy's *Almagest*, which Purbach had begun; and after the death of his friend was invited to Rome, where he made many astronomical observations. Being returned to Nuremberg in 1471, by the encouragement of Bernard Walther, a wealthy citizen, he made several instruments for astronomical observations, among which was an armillary astrolabe, like that used at Alexandria by Hipparchus and Ptolemy, with which, and a good clock, then but a late invention, he made many observations. He made ephemerides for thirty years to come, showing the lunations, eclipses, &c.; printed the works of many of the most celebrated ancient astronomers, and wrote the theory of the planets and comets, and a treatise on triangles, which contains several good theorems; computed a table of sines for every single minute, to the radius 1,000,000, and introduced the use of tangents into trigonometry.

40. After Muller's death, which happened at Rome in 1476, in his fortieth year, Bernard Walther collected his papers, and continued the astronomical observations till his own death. The observations of both were collected by order of the senate of Nuremberg, and published there in 1544 by John Schoner; they were also afterwards published in 1618 by Snellius, at the end of the observations made by the landgrave of Hesse; and lastly with those of Tycho Brahe in 1666.

41. Walther was succeeded, as astronomer at Nuremberg, by John Werner, a clergyman, who observed the motion of the comet in 1500; and wrote several tracts on geometry, astronomy, and geography, in a masterly manner; the most remarkable of which are those concerning the motion of the eighth sphere, or the fixed stars: in this tract, by comparing his own observations, made in 1514, with those of Ptolemy, Alphonsus, and others, he showed that the motion of the fixed stars, since called the precession of the equinoxes, is $1^{\circ} 10'$ in 100 years. He made also the first star of Aries 26° distant from the equinoctial point, and the obliquity of the ecliptic only $23^{\circ} 28'$; constructed a planetarium, representing the celestial motions according to the Ptolemaic hypothesis; and published a translation of Ptolemy's geography, with a commentary, in which he first proposed the method of finding the longitude at sea by observing the moon's distance from the fixed stars. Werner died in 1528, aged sixty

42. Nicolaus Copernicus rose next, and made so great a figure in astronomy, that the true system discovered, or rather renewed by him, has been ever since styled the Copernican. He restored the old Pythagorean system of the world, which had been set aside from the time of Ptolemy. About A. D. 1507 he conceived doubts of the Ptolemaic system, and entertained notions about the true one, which he gradually improved by a series of astronomical observations, and the study of former authors. By these he formed new tables, and completed his work in 1530, containing a renovation of the new system of the universe, in which all the planets are considered as revolving about the sun. This work was printed in 1543, under the care of Schoner and Osiander, by the title of *Revoluciones Orbium Cælestium*; and the author received a copy of it a few hours before his death, on the 23d of May 1543, he being then seventy years of age.

43. After the death of this great luminary of Astronomy, the science and practice of it were greatly improved by Schoner, Nonius, Gemma, Frisius, Rothman, Byrgius, the landgrave of Hesse, &c. Schoner reformed and explained the calendar; improved the methods of making celestial observations; and published a treatise on cosmography. He died four years after Copernicus. Nonius wrote several works on mathematics, astronomy, and navigation, and invented some useful and more accurate instruments than formerly, one of these was the astronomical quadrant, on which he divided the degrees into minutes, by a number of concentric circles; the first was divided into ninety equal parts or degrees, the second into eighty-nine, the third into eighty-eight, and so on to forty-six; so that the index of the quadrant always falling upon or near one of the divisions, the minutes are known by an easy computation.

44. Appian's chief work, the *Cæsarean Astronomy*, was published at Ingolstadt in 1540; in which he shows how to observe the places of the stars and planets by the astrolabe; to resolve astronomical problems by certain instruments; to predict eclipses, and to describe the figures of them; and the method of dividing and using an astronomical quadrant. To these are added observations of five comets, one of which has been supposed the same with that observed by Hevelius, and if so, it ought to have returned again in the year 1789; but astronomers were disappointed in their expectations.

45. Gemma Frisius wrote a commentary on Appian's cosmography, accompanied with many observations of eclipses; he also invented the astronomical ring, and several other instruments useful in taking observations at sea; and was the first who recommended a time-keeper for determining the longitude. Rheticus began a very extensive work, being a table of sines, tangents, and secants, to a very large radius, and to every ten seconds, or one-sixth of a minute; which was completed by his pupil Valentine Otho, and printed in 1594.

46. William IV., landgrave of Hesse Cassel, applied himself to the study of astronomy about A. D. 1561; and, with the best instruments which could then be procured, made a great

number of observations, published by Snellius in 1618, and preferred by Hevelius to those of Tycho Brahe. From these observations he formed a catalogue of 400 stars, with their latitudes and longitudes, adapted to the beginning of the year 1593.

47. Tycho Brahe, a Danish nobleman, began his studies about the same time with the Landgrave of Hesse, and observed the great conjunction of Jupiter and Saturn; but, finding the usual instruments very inaccurate, he constructed many others much larger and more exact. In 1571 he discovered a new star in the chair of Cassiopeia; which induced him, like Hipparchus on a similar occasion, to make a new catalogue of the stars; which he composed to the number of 777, and adapted their places to the year 1600. In 1576, by the favor of the king of Denmark, he built his new observatory, called Uraniburg, on the small island Huenna, opposite to Copenhagen, which he very amply furnished with many large instruments, some of them so divided as to show single minutes, and in others the arch might be read off to ten seconds. One quadrant was divided according to the method invented by Nonius, that is by forty-seven concentric circles; but most of them were divided by diagonals; a method of division invented by Richard Chancellor, an Englishman. Tycho employed his time at Uraniburg to the best advantage, till the death of the king, when, falling into discredit, he was obliged to remove to Holstein: he afterwards introduced himself to the emperor Rodolph, with whom he continued at Prague till his death in 1601. Tycho was the inventor of a system of astronomy, a kind of semi-Ptolemaic, which he vainly endeavored to establish instead of the Copernican. His numerous works, however, show that he was a man of great abilities; and his discoveries, together with those of Purbach and Regiomontanus, were collected and published together in 1621, by Longomontanus, the favorite disciple of Tycho.

48. Tycho, while residing at Prague with the emperor, prevailed on Kepler to leave the university of Glatz, and to come to him; and Tycho dying in 1601, Kepler enjoyed all his life the title of mathematician to the emperor, who ordered him to finish the tables of Tycho Brahe, which he published in 1627, under the title of *Rodolphine*. He died about A. D. 1630, at Ratisbon, where he was soliciting the arrears of his pension. From his own observations and those of Tycho, Kepler discovered several of the true laws of nature, by which the motions of the celestial bodies are regulated. He discovered that all the planets revolve about the sun, not in circular, but in elliptical orbits, having the sun in one of the foci of the ellipse; that their motions are not equal, but varying, quicker or slower as they are near to the sun, or farther from him; that the areas described by the variable line drawn from the planet to the sun, are equal in equal times, and always proportional to the times of describing them; and that the cubes of the distances of the planets from the sun, were in the same proportion as the squares of their periodical times of revolution. By observations also on comets, he concluded that they are freely

carried about among the orbits of the planets, in paths that are nearly rectilinear, but which he could not then determine.

49. At this time there were many other good proficient in astronomy; as Wright, Napier, Bayer, &c. Wright made several good meridional observations of the sun, with a quadrant of six feet radius, in the years 1594, 1595, and 1596; from which he greatly improved the theory of the sun's motion, and computed more accurately his declination, than any person had done before. In 1599 he published also, an excellent work, entitled, 'Certain Errors in Navigation discovered and detected,' containing a method which has commonly, though erroneously, been ascribed to Mercator. To Napier we owe some excellent theorems and improvements in spherics, besides the ever-memorable invention of logarithms. Bayer, a German, published his *Uranometria*, or the figures of all the constellations visible in Europe, with the stars marked on them, and accompanied by names, or the letters of the Greek alphabet; a contrivance by which they may easily be referred to with distinctness and precision.

50. About the same time, astronomy was cultivated abroad by Mercator, Maurolycus, Maginus, Homelius, Schultet, Stevin, Galileo, &c. and in England by Thomas and Leonard Digges, John Dee, Robert Flood, Harriot, &c. The beginning of the seventeenth century was particularly distinguished by the invention of telescopes, and the application of them to astronomical observations. The more distinguished early observations with the telescope, were made by Galileo, Harriot, Huygens, Hook, Cassini, &c. It is said that, from report only, Galileo made for himself telescopes, by which he discovered inequalities in the moon's surface, Jupiter's satellites, and the ring of Saturn; also spots on the sun, by which he found out the revolution of that luminary on its axis; and he discovered that the nebulae and milky way were full of small stars.

51. Mr. Harriot, who had previously been known only as an algebraist, made much the same discoveries as Galileo, and as early, if not more so, as appears by his papers in the possession of the earl of Egremont. And Mr. Horrox, a young astronomer of great talents, found out in 1633, that the planet Venus would pass over the sun's disc on the twenty-fourth of November 1639, an event which he announced only to his friend Crabtree; and these two were the only persons in the world that observed this transit. Horrox made also many other useful observations, and had even formed a new theory of the moon, taken notice of by Newton; but his early death, in the beginning of 1640, put a stop to his valuable labors.

52. Hevelius, Burgomaster of Dantzick, flourished about the same time, and observed the spots and phases of the moon; from which observations he compiled his *Selenographia*. An account of his apparatus is contained in his work entitled *Machina Cælestis*, a book now very scarce, as most of the copies were accidentally burnt, with the whole house and apparatus, in 1679. Hevelius died in 1683, aged 76.

53. Doctor Hook, a contemporary of Hevelius invented instruments with telescopic sights, and censured the others. This occasioned a sharp dispute between them; to settle which, Halley was sent over to Hevelius to examine his instruments. The two astronomers made several observations together, very much to their satisfaction; and amongst them was one of an occultation of Jupiter by the moon, when they determined the diameter of the latter to be $30' 33''$.

54. Huygens and Fontana, before the middle of the seventeenth century, greatly improved the construction of telescopes. The former constructed one of 123 feet, with which he observed the moon and planets, and discovered that Saturn was encompassed with a ring. With telescopes too, of 200 and 300 feet focus, Cassini saw five satellites of Saturn, with his zones or belts, and the shadows of Jupiter's satellites passing over his body. In 1666 Azout applied a micrometer to telescopes, to measure the diameters of the planets, and other small distances in the heavens: but an instrument of this kind had been invented before, by Gascoigne, though it was but little known abroad. To obviate the difficulties arising from the great lengths of refracting telescopes, and the aberration of the rays, Mersennus, in a letter to Descartes, first started the idea of making telescopes of reflectors, instead of lenses; and in 1663 James Gregory of Aberdeen showed how such a telescope might be constructed.

55. Sir Isaac Newton, after spending some time on the construction of both sorts of telescopes, found out the great inconvenience which arises to refractors from the different refrangibility of the rays of light; for which not finding a remedy, and pursuing the other kind, in 1672, he presented to the Royal Society two reflectors, constructed with spherical speculums. The inconvenience, however, arising from the different refrangibility of the rays of light, has since been fully obviated by Dollond.

56. Towards the end of the seventeenth, and beginning of the eighteenth century, practical astronomy rather languished; but the speculative part was carried to the highest perfection by Newton in his *Principia*, by David Gregory, Keil, and others. Soon after this, great improvements in astronomical instruments began to take place, particularly in Britain. Graham not only improved clocks and watch work, but also carried the accuracy of astronomical instruments to a surprising degree. He constructed the old eight feet mural arch at the Royal Observatory, Greenwich, and a small equatorial sector for making observations out of the meridian; but he is chiefly remarkable for contriving the zenith sector of twenty-four feet radius, and afterwards one of twelve feet and a half, with which Bradley discovered the aberration of the fixed stars. The reflecting telescope of Gregory and Newton was greatly improved by Hadley, who presented a very powerful instrument of that kind to the Royal Society in 1719. He invented also the reflecting quadrant or sector, now called by his name, presented to the society in 1731, and now universally used at sea. It appears, however, that an instrument similar to this in its princi-

ples, had been invented by Newton; and a description, with a drawing of it, was given by him to Halley, when he was preparing for his voyage in 1701, to discover the variation of the needle: it has also been asserted, that Godfrey of Philadelphia, in America, made the same discovery, and the first instrument of this kind.

57. About the middle of this century, the constructing and dividing of large astronomical instruments were carried to great perfection by Bird, and reflecting telescopes were not less improved by Short, who first executed the divided object glass micrometer, which had been proposed and described by Louville and others. Dollond also improved refracting telescopes, by means of his achromatic glasses: and the discoveries of Herschel are owing to the amazing powers of reflectors of his own construction. Thus, the astronomical improvements in the present century have been chiefly owing to the inventions of, and improvements in, the instruments, and to the establishment of regular observatories in England, France, and other parts of Europe.

58. Roemer, a celebrated Danish astronomer, first made use of a meridional telescope; and, by observing the eclipses of Jupiter's satellites, first discovered the progressive motion of light, concerning which he read a dissertation before the Academy of Sciences at Paris, in 1675. Flamsteed, appointed the first astronomer royal at Greenwich, in 1675, observed for forty-four years, and gave a catalogue of 3000 stars with their places, to the year 1689; also new solar tables, and a theory of the moon according to Horrox; likewise, in Sir Jonas Moore's *System of Mathematics*, he gave a curious tract on the sphere, showing how to construct, geometrically, eclipses both of the sun and moon, as well as occultations of the fixed stars by the moon. On his observations were founded both Halley's tables, and Newton's theory of the moon. Cassini, the first French astronomer royal, made many observations on the sun, moon, planets, and comets, greatly improved the elements of their motions, erected the gnomon, and drew the celebrated meridian line in the church of Petronia at Bologna.

59. Flamsteed was succeeded, in 1719, as astronomer royal at Greenwich, by Dr. Halley, who had been sent at the early age of twenty-one, to the island of St. Helena, to observe the southern stars and make a catalogue of them, which was published in 1679. In 1705 he published his *Synopsis Astronomiæ Cometicæ*, in which he ventured to predict the return of a comet in 1758 or 1759. He first discovered the acceleration of the moon, and gave a very ingenious method for finding her parallax, by three observed phases of a solar eclipse; published in the *Philosophical Transactions* many learned papers, and amongst them, some concerning the use that might be made of the next transit of Venus, in determining the distance of the sun from the earth; composed tables of the sun, moon, and all the planets, which are still in great repute; and recommended the method of determining the longitude, by the moon's distances from the sun, and certain fixed stars; a method which was first proposed by Warner,

and which has since been carried into execution.

60. A dispute concerning the figure of the earth took place about this time. Newton had determined, from a consideration of the laws of gravity, and the diurnal motion of the earth, that the figure of it was an oblate spheroid; but Cassini, from the measures of Picart, supposed it to be an oblong spheroid. To settle this dispute it was resolved, under Louis XV. to measure two degrees of the meridian; one near the equator, and the other as near the pole as possible. For this purpose, the Royal Academy of Sciences sent to Lapland, Maupertuis, Clairault, Camus, and Lemonnier: who were accompanied by Outhier, and Celsus, professor of anatomy at Upsal. On the southern expedition were sent Godin, Condamine, and Bouguer, to whom the king of Spain joined George Juan and Antonio de Ulloa. These set out in 1735, and returned at different times 1744, 1745, and 1746; but the former party who set out only in 1736, returned the year following; having both fulfilled their commissions. Picart's measure was revised by Cassini and De la Caille, which, after his errors were corrected, was found to agree very well with the other two; and the result of the whole served to confirm the determination of the figure before laid down by Newton. On the southern expedition, the attraction of the great mountains of Peru was found to have a sensible effect on the plumb-line of one of their largest instruments, deflecting it seven or eight seconds from the true perpendicular.

61. In 1742 Dr. Bradley succeeded, on the death of Dr. Halley, as astronomer royal at Greenwich. The accuracy of his observations enabled him to detect the smaller inequalities in the motions of the planets and fixed stars. The consequence of his accuracy was, the discovery of the aberration of light, the nutation of the earth's axis, and a much greater degree of perfection in lunar tables. He observed the places, and computed the elements of the comets which appeared in the years 1723, 1736, 1743, and 1757; made new and more accurate tables of the motions of Jupiter's satellites, and, from a multitude of observations of the luminaries, constructed a table of refractions; which has ever since been in very general estimation for its accuracy, though it is now generally admitted that it gives the refractions too small. He also, with a very large transit instrument, and a new mural quadrant of eight feet radius, constructed by Bird in 1750, made an immense number of observations for settling the places of all the stars in the British catalogue, together with nearly 1500 places of the moon, the greater part of which he compared with Mayer's tables. Bradley died in 1762.

62. Astronomers elsewhere were equally assiduous in their endeavours to promote this science. The theory of the moon was particularly considered by Clairault, D'Alembert, Euler, Mayer, Simpson, and Walmesley, and especially Clairault, Euler, and Mayer, who computed complete sets of lunar tables: those of the last of these authors, for their superior accuracy, were rewarded with a premium of £3000, and brought into use in the computation

of the Nautical Ephemeris, published by the Board of Longitude. The most accurate tables of the satellites of Jupiter were composed from observations by Wargentin, an excellent Swedish astronomer. But these have again been superseded by the more recent ones of Delambre. There is much room for improvement, however, in our knowledge of the elements of Jupiter's satellites, even with respect to the first satellites, the predicted and actual times of immersion or emersion sometimes differ to the extent of two minutes.

63. Among the many French astronomers who contributed to the advancement of the science, it was particularly indebted to De la Caille for an excellent set of solar tables. He, in 1750, went to the Cape of Good Hope to make observations in concert with the most celebrated astronomers in Europe, for determining the parallax of Mars and the moon, and thence that of the sun, which it was concluded did not much exceed ten seconds. Here he re-examined and adjusted, with great accuracy, the places of stars about the southern pole; and also measured a degree of the meridian. In Italy the science was assiduously cultivated by Bianchini, Boscovich, Frisi, Manfredi, Zanotti, and many others; in Sweden, by Wargentin, already mentioned, Blingenstern, Mallet, and Planman; and in Germany by Euler, Mayer, Lambert, Grischow, and others.

64. In 1760 all the learned societies in Europe made preparations for observing the transit of Venus over the sun, which had been predicted by Halley more than eighty years before, with the use that might be made of it in determining the sun's parallax, and the distances of the planets from the sun. The same exertions were repeated, to observe the transit in 1769, by sending observers to different parts of the world; and from the whole, Short computed that the sun's parallax was nearly $8\frac{1}{2}$ seconds, and consequently the distance of the sun from the earth about 24,114 of the earth's diameters, or ninety-six millions of miles. Bradley was succeeded, in 1762, in his office of astronomer royal, by Bliss, Savilian professor of astronomy; who, being in a declining state of health, did not long enjoy it.

65. In 1765 Bliss was succeeded by Nevil Maskelyne, who, in January 1761, was sent by the Royal Society, at a very early age, to the island of St. Helena, to observe the transit of Venus over the sun, and the parallax of the star Sirius. The first of these objects partly failed, by clouds preventing the sight of the second internal contact; and the second also, owing to Short having suspended the plumb-line by a loop from the neck of the central pin. However, he indemnified himself by many other valuable observations: thus, he observed at St. Helena, the tides; the horary parallaxes of the moon; and the going of a clock, to find by comparison with its previous going, which had been observed in England, the difference of gravity at the two places; also in going out and returning, he practised the method of finding the longitude by the lunar distances taken by Hadley's quadrant, making out rules for the use of seamen, and teaching the method to the officers on board the ship. This method was explained in the Philo-

sophical Transactions, for 1762, and more fully afterwards in the British Mariner's Guide, published in 1763. In September 1763, he sailed for the island of Barbadoes, to settle the longitude of the place, to examine Harrison's watch, and to try Irwin's marine chair. While at Barbadoes, he made many other observations, and amongst them, many relating to the moon's horary parallaxes, not yet published.

66. Maskelyne returning to England in the end of 1764, recommended to the board of Longitude the lunar method of finding the longitude; and proposed to it the project of a nautical almanack, to be calculated and published to facilitate that method. This the board agreed to, and the first volume was published for 1767, and has continued ever since to the great benefit of navigation.

67. In consequence of a proposal, made by this astronomer to the Royal Society, the project was formed of measuring accurately the effect of some mountain on the plumb-line, in deflecting it from the perpendicular; and Schehallien, in Scotland, having been found the most convenient in this island for the purpose, he went into Scotland to conduct the business; by this experiment he showed that the sum of the deflections on the two opposite sides was about $11\frac{2}{3}^{\circ}$ of a degree; and proved to the satisfaction of the whole world, the universal attraction of matter. From the data resulting from these measures, Dr. Hutton computed the mean density of the whole matter in the earth, to be about $4\frac{1}{2}$ times that of common water.

68. The discoveries of Dr. Herschel form a new era in astronomy. In 1781, he began with observations on the periodical star in Collo Ceti, and a new method of measuring the lunar mountains, none of which he made more than half a mile in height; and having constructed telescopes far more powerful than any former ones, proceeded to other observations; such as, on the rotation of the planets round their axes; on the parallax of the fixed stars; catalogues of double, triple, &c. stars; on the proper motion of the sun and solar system; on the remarkable appearances of the polar regions of the planet Mars; &c. Above all his discoveries of a new primary planet, on the 13th of March, 1781, called by him the Georgian Planet, but named the Herschel, and sometimes Uranus, by foreign astronomers, and of its six satellites, discovered since that time, has greatly enlarged the bounds of the solar system, this new planet being more than twice as far from the sun as the planet Saturn.

69. M. Piazzi, astronomer royal at Palermo, discovered on January 1st, 1801, another planet moving in an orbit between Mars and Jupiter. This planet has been named Ceres. Another was discovered on March 28th, 1802, by Dr. Olbers of Bremen, and named Pallas; a third was discovered and named Juno by Mr. Harding of Lilienthal; and a fourth by Dr. Oliers, and named Vesta, on March 29th, 1807. These planets are all very small, and all so nearly at the same distance from the sun, and moving in orbits differing so little either in eccentricity or declination, that they have by some been con-

jectured to be fragments of a larger planet, which from some explosion had been burst, and its parts scattered abroad in space.

It is probable that as astronomical instruments become more improved, further discoveries of the same kind will be made, and that the boundaries of the solar system may be enlarged by the discerning of planets which circulate round the sun even beyond the orbit of the Georgian planet.

71. Dr. Maskelyne was succeeded at the Greenwich observatory in 1811, by J. Pond, esq. the present astronomer royal, under whose management the business of this important institution has been kept in full activity. The number of instruments has been greatly increased. The use of the mural quadrant has been abandoned for that of the circle, two of which, one by Troughton, and one by T. Jones, are in constant use, and give results which accord with each other in a manner altogether surprising. The most important discoveries may be hoped for from the skill and activity with which the splendid instruments at Greenwich are managed. All indeed that appears wanting in that institution, is a telescope of the first class to follow up the discoveries in sidereal astronomy, which conferred such splendor on the name of Herschel. But we are glad to perceive that this department of the science is likely to be carried to a degree of perfection which few would have hoped for, by Mr. Herschel, junior, the worthy and able son of the great astronomer, and his friend Mr. South, whose recent publication on the motion of double stars does them the highest credit.

72. On the continent of Europe, the greatest ardor is at present evinced in the cultivation of this science. The labors of Schumacher at Altona, are unintermitted and most valuable. He may be considered at present as a common bond among astronomical men. Grass at Gottingen, Littrow, at Venice; Bessel, at Konigsberg; Struve, at Dorpat; Zach, at Genoa; and a host of other individuals distinguished for their labors and their zeal, have devoted themselves to astronomy.

73. In our own country, it would be injustice to pass over the names of Woodhouse and Brinkley, whose eminence in this science is of the most distinguished kind.

74. Another striking feature of the present day is the formation of 'The Astronomical Society of London,' an institution whose only object is the cultivation of astronomical science. This society includes among its members almost every individual known to the world as distinguished for astronomical knowledge. The memoirs of the society, of which the third part is just ready for publication, are very valuable and interesting.

75. The university of Cambridge has recently evinced its sense of the importance of a practical knowledge of this science, by the erection of an observatory on the most splendid scale; and the English government has also shown by the recent order for the establishment of an observatory at the Cape of Good Hope, that the importance which it has always attached to the cultivation of this science, has suffered no abatement.

76. Historical accounts and lists of the principal authors and writings on this science, are contained in Weidler's and Bailly's History of Astronomy. Adam, Vossius, Bayle, Chauffepie, Nicéron, Perraut, the chronological table of Riccioli, and that of Sherburn, at the end of his edition of Manilius; and the first volume of De la Lande's astronomy, may also be consulted. The more modern and popular books on astronomy are very numerous and well known; as those of Ferguson, Long, Emerson, Vince, De la Lande, Leadbetter, Brent, Keil, Whiston, Wing, Street, Bonnycastle, Gregory, Brinkley, &c. but the recent treatise on astronomy by Woodhouse, is by far the most complete that has appeared in the English language.

PART I.

OF THE APPEARANCES OF THE CELESTIAL BODIES.

SECT. I.—OF THE CELESTIAL BODIES, AS SEEN BY THE NAKED EYE.

77. The most obvious celestial phenomenon is the daily rising of the sun in the east, and his setting in the west; next to which is that of the moon and stars appearing, and keeping the same westerly course. These cannot be long taken notice of before we must perceive that neither the sun nor moon always rise exactly in the same point of the heavens. If we observe the sun, from the beginning of March, we find that he seems to rise almost every day sensibly more to the northward, than he did the day before, to continue longer above the horizon, and to be more elevated at mid-day, till towards the end of June, when he is observed to move backward in the same manner: this retrograde motion continues beyond the middle of December, when he begins again to move forwards, and so on.

78. When the new moon (as she is called, at her early period,) first becomes visible, she appears in the western part of the heavens, at no great distance from the sun. Every night she increases in size, and removes to a greater distance from the sun; till at last she appears in the eastern part of the horizon, just at the time the sun disappears in the western. After this she gradually moves farther and farther eastward, rising every night later and later, till at last she seems to approach the sun as nearly in the east as she did in the west, and rises only a little before him in the morning, as in the first part of her course she set in the west not long after him. All these different appearances are completed in the space of a month; after which they begin in the same order as before.

79. Several of the stars neither rise in the east, nor set in the west, but seem to turn round an immovable point, near which is placed a single star called the pole, or pole star. This point is more or less elevated according to the different parts of the earth from which we take our view. The inhabitants of Lapland, for instance, see it much more elevated above the horizon than we do; we see it more elevated than the inhabitants of France and Spain; and they, again, see it more elevated than the inhabitants of Barbary. By continually tra-

velling south, this star at last seems depressed in the horizon, and another point appears directly opposite to it, round which the stars in the southern part of the horizon seem to turn. In this part of the heavens, however, there is no star so near the pole as there is in the northern part: nor is the number of stars in the southern part of the heavens so great as in the northern part.

80. Supposing us still to travel southward, the north pole entirely disappears, and the whole atmosphere appears to turn round a single point in the south, as the northern hemisphere appears to us to turn round the pole star. The general appearance of the heavens, therefore, is that of a vast concave sphere, turning round two points fixed in the north and south parts of it, once in twenty-four hours.

81. The majority of the stars keep their places with respect to one another; that is, if we observe two stars having a certain apparent distance from each other one night, they seem to have the same every succeeding night. But all the stars in the heavens do not appear to be of this fixed kind: some of them change their places, with regard to the fixed stars, and to one another. Of these ten are at present known. They are distinguished by the appellation of planets, from *πλαναω*, to wander, and are called by the names of Mercury, Venus, Mars, Ceres, Pallas, Juno, Vesta, Jupiter, Saturn, and Herschel, Uranus, or the Georgium Sidus. The fixed stars are likewise distinguished from the planets by continually exhibiting that appearance which is called the scintillation or twinkling of the stars.

82. Mercury is a small star which emits a very bright white light; but, by always keeping near the sun, he is seldom to be seen; and when he does make his appearance, his motion toward the sun is so swift, that he can only be discerned for a short time, a little after sun-set, and again a little before sun-rise.

83. Venus the most beautiful star in the heavens, known by the names of the morning and evening star, keeps near the sun, though at almost double the distance of Mercury. She is never seen in the eastern quarter of the heavens when the sun is in the western; but seems to attend him in the evening, or to give notice of his approach in the morning.

84. Mars is of a red fiery color, and gives a much duller light than Venus, though sometimes he equals her in size. He is not subject to the same limitation in his motions as Mercury or Venus; but appears sometimes very near the sun, and sometimes at a great distance from him; sometimes rising when the sun sets, or setting when he rises. Of this planet it is remarkable, that when he approaches any of the fixed stars, they change their color, grow dim, and often become totally invisible, though at some little distance from the body of the planet: but Herschel thinks this has been exaggerated by former astronomers.

85. Jupiter and Saturn often appear at great distances from the sun. The former shines with a bright white light, and the latter with a pale faint one; and the motion of Saturn among the

fixed stars is so slow, that, unless carefully observed, he will not be thought to move at all. Herschel's motion is still slower, and he is seldom to be seen without a telescope.

86. The apparent magnitudes of these bodies are very different at different times. Every person must have observed that Venus is not always equally big; and this apparent difference of magnitude is so remarkable, that she appears no less than thirty-two times larger at some seasons than at others. This increase of magnitude is likewise very remarkable in Mars and Jupiter, but less so in Saturn, Mercury and Herschel. These planets by no means appear to us to move regularly in the heavens, but, on the contrary, sometimes go forward, sometimes backward, and sometimes seem to be stationary.

87. There are other moving bodies, besides the planets, which appear at uncertain intervals, and with a very different aspect. These are very numerous, and upwards of 500 are recorded as having visited our system. They are called Comets, from *κομητης*, hairy, having a long tail, somewhat resembling the appearance of hair. This, however, is not always the case; for some comets have appeared as round as planets: but in general they have a luminous matter diffused around them, or projecting out from them, which to appearance very much resembles the Aurora Borealis. They appear to come in a direct line towards the sun, as if they were going to fall into his body; and after having disappeared for some time, in consequence of their proximity to that luminary, fly off again on the other side as fast as they came, projecting a tail much greater and brighter in their recess; but, getting daily at a farther distance from us in the heavens, they continually lose some of their splendor, and at last totally disappear.

88. The apparent magnitude of comets is very different; sometimes they appear only of the bigness of the fixed stars; at other times they equal the diameter of Venus, and sometimes even of the sun or moon. In 1652 Hevelius observed a comet which seemed not inferior to the moon in size, though it was not so bright, but appeared with a pale and dim light. These bodies also sometimes lose their splendor suddenly, while their apparent bulk remains unaltered. With respect to their apparent motions, they have all the inequalities of the planets; sometimes seeming to go forwards, sometimes backwards, and sometimes to be stationary.

89. The fixed stars are liable to changes: several observed by the ancients are now no more to be seen; and new ones have appeared which were unknown to the ancients. Some of them have also disappeared for some time, and again become visible. At times some have been observed to distinguish themselves by superlative lustre; but afterwards decreasing, to vanish by degrees, and to be no more seen. One of these stars being first seen and observed by Hipparchus, set him upon composing a catalogue of the fixed stars, that by it posterity might learn whether any of the stars perish, and others are produced afresh. After several ages Tycho Brahe observed another new star, which put him on the same design. Of these changes accounts have

been given by Halley, Montanere, and Pigot, in the Philosophical Transactions. As a specimen of these phenomena we shall here insert an extract from the former.

90. 'The first new star in the chair of Cassiopeia was not seen by Cornelius Gemma on the 8th of November, 1572, who says, he that night considered that part of the heavens in a very serene sky, and saw it not: but that the next night November 9, it appeared with a splendor surpassing all the fixed stars, and scarcely less bright than Venus. This was not seen by Tycho Brahe before the 11th of the same month: but from thence he assures us that it gradually decreased and died away, so that in March 1574, after sixteen months, it was no longer visible; and at this day no signs of it remain. The place, thereof, in the sphere of fixed stars, by the accurate observations of Tycho, was $0^{\circ} 9' 17'' a$ $1^{\text{ma}} * \gamma^{\text{is}}$, with $53^{\circ} 45' N$. lat.

91. 'Such another star was seen and observed by the scholars of Kepler, to begin to appear Sept. 30. O. S. anno 1604, and which was not to be seen the day before. It broke out at once with a lustre surpassing that of Jupiter; and like the former died away gradually, and in much about the same time disappeared totally, there remaining no footsteps thereof in January 1605. This was near the ecliptic, following the right leg of Serpentarius; and by the observations of Kepler and others, was in $7^{\circ} 20' 00'' a$ $1^{\text{ma}} * \gamma$, with north lat. $1^{\circ} 56'$. These two seem to be of a distinct species from the rest, and nothing like them has appeared since.

92. 'But between them, viz. in 1596, we have the first account of the wonderful star in Collo Ceti, seen by David Fabricius on the 3d of August, as bright as a star of the third magnitude, which has been since found to appear and disappear periodically; its period being precisely seven revolutions in six years, though it returns not always with the same lustre. Nor is it ever totally extinguished, but may at all times be seen with a six feet tube. This was singular in its kind till that in Collo Cygni was discovered. It precedes the first star of Aries $1^{\circ} 40'$, with $15^{\circ} 57'$ south lat.

93. 'Another new star was first discovered by William Jansonius in the year 1600, in pectore, or rather in eductione, Colli Cygni, which exceeded not the third magnitude. This having continued some years became at length so small as to be thought by some to have disappeared entirely; but in the years 1657, 1658, and 1659, it again arose to the third magnitude; though soon after it decayed by degrees to the fifth or sixth magnitude; and at this day is to be seen as such in $9^{\circ} 18' 38'' a^{\text{ma}} * \gamma$, with $55^{\circ} 29'$ north lat.

94. 'A fifth new star was first seen by Hevelius in 1600, on July 15, O. S. as a star of the third magnitude, but by the beginning of October was scarce to be perceived by the naked eye. In April following it was again as bright as before, or rather greater than of the third magnitude, yet wholly disappeared about the middle of August. The next year, in March 1672, it was seen again, but not exceeding the sixth magnitude: since when it has been no farther visible, though we have frequently sought for its

eurn; its place is $9^{\circ} 32' 17''$ $a 1^{\text{ma}}$ α γ , and has lat. north $47^{\circ} 28'$.

95. 'The sixth and last is that discovered by Mr. G. Kirch in the year 1686, and its period determined to be of 40½ days; and though it rarely exceeds the fifth magnitude, yet it is very regular in its returns, as we found in the year 1714. Since then we have watched, as the absence of the moon and clearness of the weather would permit, to catch the first beginning of its appearance in a six feet tube, that, bearing a very great aperture, discovers most minute stars. And on June 15, last, it was first perceived like one of the very least telescopic stars; but in the rest of that month and July it gradually increased so as to become in August visible to the naked eye, and so continued all the month of September. After that it again died away by degrees, and on the 8th of December, at night, was scarcely discernible by the tube; and, as near as could be guessed, equal to what it was at its first appearance on June 15th; so that this year it has been seen in all nearly six months, which is but little less than half its period; and the middle, and consequently the greatest brightness, falls about the 10th of September.'

96. The galaxy or milky way is a remarkable appearance in the heavens, being a broad ring of a whitish color surrounding the whole celestial concave, whose light is now known to proceed from vast clusters of stars, discoverable only by the telescope. Mr. Brydone, in his journey to the top of Mount Etna, found this phenomenon to make a glorious appearance, 'like a pure flame (as he expresses it) that shot across the heavens.'

97. The only other appearances which are very observable by the unassisted eye, are those obscurations of the sun and moon commonly called eclipses. These are too well known, and attract the attention too much, to need any particular description. We have, however, accounts very well authenticated, of obscurations of the sun continuing for a much longer time than a common eclipse possibly can do, and likewise of the darkness being much greater than usual on such occasions.

SECT. II. OF THE CELESTIAL BODIES AS SEEN THROUGH TELESCOPES.

98. Although the sun, to the naked eye, is extremely bright and splendid, he is frequently observed, even through a telescope of but very small powers, to have dark spots on his surface, which are said to have been first discovered in 1611; and the honor of the discovery is disputed betwixt Galileo and Scheiner, a German Jesuit at Ingolstadt. But whatever merit Scheiner might have in the priority of the discovery, it is certain that Galileo far exceeded him in accuracy; though Scheiner's work has considerable merit, as containing observations selected from above 3000 made by himself.

99. It appears from the papers of Harriot, the English algebrast, which were found in 1784, at the seat of the earl of Egremont in Sussex, that he made a great number of observations upon the solar spots much about the

same time; and Dr. Zach, astronomer to the duke of Saxe-Gotha, in an account of Harriot's papers, published in 1788, says that there is the greatest probability of Harriot being the first discoverer of these spots, even before either Galileo or Scheiner. Galileo's first produced observations are only for June 2, 1612, and those of Scheiner of the month of October in the same year, whereas Harriot's, as appears from his MSS, are of December 8, 1610.

100. There is great variety in the magnitudes of the solar spots; the difference is chiefly in superficial extent of length and breadth; their depth or thickness is very small: some have been so large as by computation to be capable of covering the whole surface of the earth, or even five times its surface. The diameter of a spot, when near the middle of the disk, is measured by comparing the time it takes in passing over a cross hair in a telescope, with the time wherein the whole disk of the sun passes over the same hair. It may also be measured by the micrometer; and thus we may judge how many times the diameter of the spot is contained in the diameter of the sun.

101. Spots are subject to increase and diminution of magnitude, and seldom continue long in the same state. They are of various shapes; most of them having a deep black nucleus, surrounded by a dusky cloud, whereof the inner parts near the black are a little brighter than the outskirts. They change their shapes, something in the manner that our clouds do, though not often so suddenly; thus what is of a certain figure to day, will to-morrow, or perhaps in a few hours, be of a different one; what is now but one spot will in a little time be broken into two or three; and sometimes two or three spots will coalesce, and be united into one. The number of spots on the sun is very uncertain; sometimes there are a great many, sometimes very few, and sometimes none at all.

102. Scheiner made observations on the sun from 1611 to 1629; and says he never found his disk quite free from spots, excepting a few days in December, 1624. At other times he frequently saw twenty, thirty, and in the year 1625, he was able to count fifty spots on the sun at a time. In an interval afterwards of twenty years, from 1650 to 1670, scarcely any spots were to be seen, and since that time some years have furnished a great number of spots, and others none at all; but since the beginning of the last century, not a year has passed wherein some were not seen.

103. It is evident from these various appearances that the spots are not endowed with any permanency, nor at all regular in their shape, magnitude, number, or time of appearance or continuance. Hevelius observed one that arose and vanished in sixteen or seventeen hours; and no one has been observed to continue longer than seventy days: those spots that are formed gradually are gradually dissolved, while those that arise suddenly are for the most part suddenly dissolved. When a spot disappears, that part where it was, generally becomes brighter than the rest of the sun, and continues so for several days: on the other hand, those bright parts

called *faculæ* (as the others are called *maculæ*) sometimes turn to spots.

104. The solar spots appear to have a motion across the sun's disk. Every spot, if it continues long enough without being dissolved, appears to enter the sun's disk on the east side, to go from thence with the velocity continually increasing till it has gone half way, and then to move slower and slower till it goes off at the west side; after which it disappears for about the same space of time that it spent in crossing the disk, and then enters upon the east side again, nearly in the same place, and crosses it in the same track, and with the same unequal motion as before. The motion of the spots is in the order of the signs (the same way that all motions in the solar system, those of the comets alone excepted, are performed); and therefore, as the earth revolves round the sun the same way with the solar spots, one of these will appear to remain longer on the disk than it would otherwise do if the earth remained at rest.

105. The face of the sun, when clear of spots, seen by the naked eye through a smoked or colored glass, or through a thin cloud, or the vapours near the horizon, appears all over equally luminous; but when viewed through the telescope, the glasses being smoked or colored, the middle of the disk appears brighter than the outskirts, because the light is darted more directly towards us from the middle than from any other part, and the *faculæ* appear more distinctly near the sides, as being on a darker ground than in the middle.

106. All the phenomena of the solar spots, as delivered by Scheiner and Hevelius, may be summed up in the following particulars: 1. Every spot which has a nucleus, or considerably dark part, has also an umbra, or fainter shade, surrounding it. 2. The boundary betwixt the nucleus and umbra is always distinct and well defined. 3. The increase of a spot is gradual, the breadth of the nucleus and umbra dilating at the same time. 4. In like manner, the decrease of a spot is gradual; the breadth of the nucleus and umbra contracting at the same time. 5. The exterior boundary of the umbra never consists of sharp angles; but is always curvilinear, how irregular soever the outline of the nucleus may be. 6. The nucleus of a spot, whilst on the decrease, often changes its figure by the umbra encroaching irregularly upon it, insomuch that in a small space of time new encroachments are discernible, whereby the boundary betwixt the nucleus and umbra is perpetually varying. 7. It often happens, by these encroachments, that the nucleus of a spot is divided into two or more nuclei. 8. The nuclei of the spots vanish sooner than the umbræ. 9. Small umbræ are often seen without nuclei. 10. An umbra of any considerable size is seldom seen without a nucleus in the middle of it. 11. When a spot which consists of a nucleus and umbra is about to disappear, if it is not succeeded by a *facula*, or spot brighter than the rest of the disk, the place where it was is soon after not distinguishable from the rest.

107. Dr. Wilson, in the *Phil. Trans.* vol. *lxiv.*

mentions the following appearances: 1. When the spot is about to disappear on the western edge of the sun's limb, the eastern part of the umbra first contracts, then vanishes, the nucleus and western part of the umbra remaining; then the nucleus gradually contracts and vanishes, while the western part of the umbra remains. At last this disappears also; and if the spot remains long enough to become again visible, the eastern part of the umbra first becomes visible, then the nucleus; and when the spot approaches the middle of the disk, the nucleus appears environed by the umbra on all sides, as already mentioned. 2. When two spots lie very near to one another, the umbra is deficient on that side which lies next the other spot; and this will be the case, though a larger spot should be contiguous to one much smaller; the umbra of the large spot will be totally wanting on that side next the small one. If there are little spots on each side of the large one, the umbra does not totally vanish; but appears flattened or pressed in towards the nucleus on each side. When the little spots disappear, the umbra of the large one extends itself as usual. This circumstance, he observes, may sometimes prevent the disappearance of the umbra in the manner above mentioned; so that the western umbra may disappear before the nucleus, if a small spot happens to break out on that side.

108. Mr. Wollaston observes, in the same volume, p. 337, that the appearances mentioned by Wilson are not constant; and as much depends on the accuracy of observers and the situation of the spots on the sun's orb, it is probable that the observation will continue to differ in minute particulars, till a consistent theory is formed, by which the cause of these phenomena may be explained. The spots are not confined to one part of the sun's disk; though they are generally observed about his polar regions. The paths they describe in their course over the disk are exceedingly different; sometimes being straight lines, sometimes curves, sometimes descending from the northern to the southern parts of the disk, sometimes ascending from the southern to the northern, &c. These appearances are increased by the inclination of the solar axis to the plane of the earth's orbit; from whence it arises, that the part described by a spot which is on a circle parallel to the solar equator sometimes appears oval, and at others a straight line, according to the position of the earth with respect to the sun. Besides these spots, there are others which sometimes appear very round and black, travelling over the disk of the sun in a few hours, totally unlike the others, and proceeding from an interposition of the planets Mercury and Venus between the earth and the sun. Excepting the two kinds of spots above-mentioned, however, no kind of object is discoverable on the surface of the sun, but he appears like an immense ocean of light.

109. The appearance of the Moon is very different. Many darkish spots appear in her to the naked eye; and through a telescope their number is prodigiously increased; she also appears very plainly to be more protuberant in the middle than at the edges, or to have the figure of

a globe, and not a flat circle. When the moon is gibbous or horned, the one side appears very ragged and uneven, but the other pretty well defined and circular. The spots in the moon always keep their places exactly; never vanishing, or going from one side to the other, as those of the sun do. We sometimes see more or less of the northern or southern, the eastern or western part of the disk or face; which is owing to what is called her libration. Plate IV. fig. 1, gives a representation of the full moon in her mean libration, with the principal spots according to Riccioli, Cassini, and Mayer.

110. Mercury, when looked at through telescopes magnifying about 200 or 300 times, appears equally luminous throughout his whole surface, without the least dark spot. He appears to have the same phases with the moon, being sometimes horned, sometimes gibbous, and sometimes shining almost with a round face, though not entirely full, because his enlightened side is never turned directly towards us.

111. Dr. Herschel has frequently examined Mercury with telescopes of highly magnifying powers; but he always appeared equally bright on every part of his disk, without any dark spot or ragged edge. But Schroeter, who has so much distinguished himself in this department of astronomy, affirms that he has not only seen spots, but even mountains in Mercury; and that he has succeeded in measuring the altitude of two of them. He makes the elevation of the higher of these about ten English miles and three-quarters, or about thrice the height of the highest mountain on our earth: but where so small an error in the admeasurement of the angle on which the computation is founded would entail so great a mistake in the result, we can only consider this determination of the height of the mountains of Mercury, as a strong evidence that considerable elevations do exist on that planet. By examining the variation on the appearance of Mercury's horns from day to day, Schroeter found the period of his diurnal rotation to be about twenty-four days, five hours, and twenty-eight minutes. Considerable difference of opinion exists respecting the atmosphere of this planet: if it possesses any, it certainly at the centre subtends a very small angle.

112. Venus, when viewed through a telescope, is rarely seen to shine with a full face, but has phases and changes like those of the moon, increasing, decreasing, being horned, gibbous, &c. Her illuminated part is constantly turned towards the sun; being directed towards the east when she is a morning star, and towards the west when an evening star. Her different phases were first discovered by Galileo. Dr. Herschel has published, in the *Phil. Trans.* for 1793, a long series of observations on this planet, from which he concludes, 1. that the planet revolves about its axis, but that the period, and the position of the axis, are uncertain; 2. that the planet's atmosphere is very considerable; 3. that there are probably hills and inequalities upon its surface, though he has not been able to see much of them, owing, perhaps, to the density of its atmosphere; and, 4. that this planet is somewhat larger than the earth,

instead of being less, as former astronomers have imagined. Schroeter, also, in the *Phil. Trans.* for 1792, published the result of a series of observations on this planet, which were begun in 1780. He infers from his observations that Venus has an atmosphere of great density and height, and that many of her mountains are five or six times as high as those of the earth.

113. Much larger and more remarkable spots have been perceived on the disk of Mars than on that of any other primary planet. By very accurate observations, Herschel has determined the proportion between the polar and equatorial diameters, and the length of the day in this planet. He has also given some good conjectures on its seasons and its atmosphere: the latter it is now ascertained to have; but though considerable, the atmosphere is not of so great an extent as the conjectures on former observations led astronomers to imagine. By very accurate observations, Dr. Herschel has determined that the proportion of his polar and equinoctial axis is as 1272 to 1355, or nearly as 15 to 16; that its time of rotation on its axis is 24 h. 22 m. and that the inclination of the axis of Mars to the orbit of the earth is $59^{\circ}42'$. From the great obliquity of this planet's axis of rotation, the polar regions of it are alternately presented towards the earth, and a much better opportunity is thereby offered for examining its surface than that of any other planet. This, however, is in some degree counterbalanced by the very dense atmosphere with which this planet is surrounded. It is not a little remarkable, that when either pole emerges into the light of the sun, it exhibits a very striking brilliancy, something like what would arise from its being covered with snow. The analogy between this phenomenon and what annually takes place on our own globe, is too obvious to escape notice.

114. The planet Ceres is of a red color, and appears about the size of a star of the eighth magnitude. It is surrounded by a very dense and extensive atmosphere, in which very great and sudden changes are observed to take place. The estimates that have been made of this planet's diameter are a striking instance of the difficulty of measuring the apparent diameters of such small objects. Herschel makes its diameter about 163 miles; and Schroeter about 1624, or nearly ten times as much. Its periodical revolution round the sun is accomplished in about four years, seven months, and ten days.

115. Pallas is nearly of the same size as Ceres, but not quite of so red an appearance. Its period of revolution has been computed to be about four years, ten months, and eleven days; and its diameter has been estimated at from eighty to upwards of 2000 miles. It has also an atmosphere, but of less extent than that of Ceres; but it differs from that and all other planets in the great inclination of its orbit. The planets generally circulate in planes that do not deviate much from the plane of the ecliptic; but the orbit of Pallas is inclined about thirty-five degrees, nearly five times as much as that of any other planet.

116. Juno is of a reddish color, and is surrounded by an atmosphere of considerable den-

sity. Its diameter is allowed by all observers to be less than that of either Ceres or Pallas. It differs from all other planets in the eccentricity of its orbit ; being, when at its greatest distance from the sun, at double the least distance. The period of its revolution is about four years and 128 days.

117. Vesta appears like a star of the sixth magnitude, and may on a clear night be sometimes seen with the naked eye. Its light is whiter and more intense than any of the other three small planets. Its apparent diameter has been estimated at about half that of the fourth satellite of Saturn ; and yet it is very remarkable that its light is so intense, that Schroeter saw it several times with his naked eye, while it requires a telescope of considerable power to see the fourth or indeed any satellite of Saturn. This planet revolves in about three years, sixty-six days, and four hours. The orbits of all these four little planets (which from their smallness have been called Asteroids) intersect each other in various places ; and the points of intersection are continually varying from the changes in the places of their aphelia.

118. Jupiter has the same general appearance with Mars, only that the belts on his surface are much larger and more permanent. Their number is very variable, as sometimes only one, and at other times no fewer than eight, may be perceived. They are generally parallel to one another, but not always so ; and their breadth is likewise variable, one belt having been observed to grow narrow, while another in its neighbourhood has increased in breadth, as if the one had flowed into the other. The time of their continuance is very uncertain, sometimes remaining unchanged for three months ; at others, new belts have been formed in an hour or two. In some of these belts large black spots have appeared, which moved swiftly over the disk from east to west, and returned in a short time to the same place ; from whence the rotation of this planet about its axis has been determined.

119. The figure of Jupiter is evidently an oblate spheroid, the longest diameter of his disk being to the shortest as thirteen to twelve. His rotation is from west to east, like that of the sun, and the plane of his equator is very nearly coincident with that of his orbit ; so that there can scarcely be any difference of seasons in that planet. His rotation has been observed to be somewhat quicker in his aphelion than his perihelion.

120. The most remarkable circumstance attending this planet, is his having four moons or satellites, which constantly revolve round him at different distances. These are all supposed to move in ellipses ; though the eccentricities of all of them are too small to be measured, excepting that of the fourth ; and even this amounts to no more than 00·07 of its mean distance from the primary.

121. The periodic times and distances of these satellites, in semidiameters of Jupiter, as well as in English miles, the angles under which their orbits appear, as seen from the earth, at its mean distance from Jupiter, taken from the latest and most exact observations, are as follow :

No.	Periodic times.	Distances in		Angles of Orb.
		Semi-diam.	Miles.	
1	1d. 18h. 27' 34"	5 $\frac{2}{3}$	266,000	3 55"
2	3 13 13 42	9 $\frac{1}{39}$	423,000	6 14
3	7 3 42 36	14 $\frac{1}{13}$	676,000	9 58
4	16 16 32 9	25 $\frac{3}{10}$	1,189,000	17 30

122. The nodes of these satellites are not in the same place. All of them, by reason of their immense distance, seem to keep near their primary, and their apparent motion is a kind of oscillation like that of a pendulum, going alternately from their greatest distance on one side to the greatest distance on the other, sometimes in a straight line, and sometimes in an elliptic curve. When a satellite is in its superior semicircle, or that half of its orbit which is more distant from the earth than Jupiter is, its motion appears to us direct, according to the order of the signs ; but in its inferior semicircle, when it is nearer to us than Jupiter, its motion appears retrograde ; and both these motions seem quicker the nearer the satellites are to the centre of the primary, slower the more distant they are, and, at the greatest distance of all, they appear for a short time to be stationary.

123. It is evident, from this account of the system of Jupiter and his satellites, that occultations of them must frequently happen by their going behind their primary, or by coming in betwixt us and it. The former takes place when they proceed towards the middle of their upper semicircle ; the latter when they pass through the same part of their inferior semicircle. Occultations of the former kind happen to the first and second satellite ; at every revolution, the third very rarely escapes an occultation, but the fourth more frequently by reason of its greater distance. It is seldom that a satellite can be discovered upon the disk of Jupiter, even by the best telescopes, excepting at its first entrance, when, by reason of its being more directly illuminated by the rays of the sun than the planet itself, it appears like a lucid spot upon it. Sometimes, however, a satellite, in passing over the disk, appears like a dark spot, and is easily to be distinguished. This is supposed to be owing to spots on the body of these secondary planets ; and it is remarkable, that the same satellite has been known to pass over the disk at one time as a dark spot, and at another so luminous that it could not be distinguished from Jupiter himself, except at its coming on and going off.

124. To account for this phenomenon, we must say that either the spots are subject to change, or, if they be permanent like those of our moon, that the satellites at different times turn different parts of their globes towards us. Possibly both these causes may contribute to produce the phenomena just mentioned. For these reasons also both the light and apparent magnitude of the satellites are variable ; for the fewer spots there are upon that side which is turned towards us, the brighter it will appear ; and, as the bright side

only can be seen, a satellite must appear larger the more of its bright side it turns towards the earth, and the less so the more it happens to be covered with spots. The fourth satellite, though generally the smallest, sometimes appears bigger than any of the rest; the third sometimes seems least, though usually the largest; nay, a satellite may be so covered with spots as to appear less than its shadow passing over the disk of the primary, though we are certain that the shadow must be smaller than the body which casts it.—To a spectator placed on the surface of Jupiter, each of these satellites would put on the various appearances of the moon; but they appear to us always round, having constantly their enlightened half turned towards the earth.

125. When these moons pass through their inferior semicircles, they cast a shadow upon Jupiter, and thus cause an eclipse of the sun to his inhabitants; and in some situations this shadow may be observed going before or following the satellite. Herschel says, 'April 6th, 1780, I had a fine view of Jupiter, and saw, as soon as I looked into the telescope, without any previous notice of it, the shadow of the third satellite, and the satellite itself on the lower part of the disk. The shadow was so black and well defined, that I attempted to measure it, and found its diameter, by the microm-ter, to be $1''$.562.' See plate XI. fig. 2. On the other hand, in passing through their superior semicircles, the satellites may be eclipsed in the same manner as our moon is to us, by passing through the shadow of Jupiter; and this is actually the case with the first, second, and third of these bodies; but the fourth, by reason of the largeness of its orbit, passes sometimes above or below the shadow, as is the case with our moon. The beginnings and endings of these eclipses are easily seen by a telescope when the earth is in a proper situation with regard to Jupiter and the sun; but when this or any other planet is in conjunction with the sun, the superior brightness of that luminary renders both it and the satellites invisible. From the time of its first appearing after a conjunction until near the opposition, only the immersions of the satellites into his shadow, or the beginnings of the eclipses are visible: at the opposition, only the occultations of the satellites, by going behind or coming before their primary, are observable; and from the opposition to the conjunction, only the immersions, or end of the eclipses are to be seen. For let *S*, plate VI. fig. 8, be the sun; *J* Jupiter and its shadow; *A* and *P* the earth, before and after the opposition of Jupiter; *S* *p* the path of the first satellite in the shadow; *A* *t* a tangent to Jupiter. When the first satellite enters the shadow, the apparent distance of it from the body of Jupiter is *tA*s; but at its emersion, the line *pA* passes through Jupiter, and therefore the emersion is not visible; but after opposition, the earth being at *P*, the emersion, and not the immersion, will be seen. The same things take place with respect to the second satellite. If *m* *o* *o* be the path of the third satellite, *m* *A* frequently lies without the body of Jupiter, and therefore both the immersion and emersion will be visible; the satellite disappears

and re-appears again at a distance from the body of Jupiter, and on the same side.

126. This is exactly true in the first satellite, of which we can never see an immersion with its immediately subsequent emersion: and it is but rarely that they can be both seen in the second; as in order to their being so, that satellite must be near one of its limits, at the same time that the planet is near its perihelion and quadrature with the sun. With regard to the third, when Jupiter is more than 46° from conjunction with, or opposition to, the sun, both its immersions and immediately subsequent emersions are visible; as they likewise are in the fourth, when the distance of Jupiter from conjunction or opposition is 24° . It had long been suspected that the satellites of this planet revolved on their axis; and Dr. Herschel has discovered that each of them revolves about its axis in the time of its revolution round its primary; thus furnishing another striking correspondence between the satellites of the other planets and the moon, the satellite of the earth. They must be very magnificent objects to the inhabitants of Jupiter. The first of them appears to them four times larger than our moon does to us, and goes through all the changes of the moon in the short space of forty-two hours, within which period it is itself eclipsed, and causes an eclipse of the sun on the surface of Jupiter.

127. When Jupiter is in quadrature with the sun, the earth is farthest out of the line that passes through the centres of the sun and Jupiter, and therefore the shadow of the planet is then most exposed to our view: but even then the body of the planet will hide from us one side of that part of the shadow which is nearest to it, through which the first satellite passes; which is the reason that, though we see the entrance of that satellite into the shadow, or its coming out from thence, as the earth is situate on the east or west side thereof, we cannot see them both; whereas the other satellites, going through the shadow at a greater distance from Jupiter, their ingress and egress are both visible. The orbits of the satellites are inclined to the plane of Jupiter's orbit, as is evident from the unequal duration of the eclipses of the same satellite. The fourth satellite, like our own moon, is sometimes in opposition to the sun, without being eclipsed. The third and fourth satellites often disappear in the shadow, and re-appear again on the same side of Jupiter; but only the beginnings or the endings of the eclipses of the first and second satellites are visible. The relative distances of these moons from their primary, are shown in plate VII. fig. 13.

127*. We cannot close this account of Jupiter without noticing two curious results obtained by La Place, with respect to the satellites of Jupiter; results which agree with observation in a remarkable manner. The first is, that if m' , m'' , m''' , represent the mean motions of the first, second, and third satellites respectively, the $m' + 2m'' - 3m'''$, is always equal to nothing. The second is, that if l' , l'' , and l''' represent the mean longitudes of the satellites, as seen from the centre of Jupiter, then $l' - 3l'' + 2l''' =$

180°. It follows from this theorem, that the first three satellites of Jupiter can never all be eclipsed together. For if it was possible, then l' , l'' , and l''' would be equal, and consequently $l' - 3l'' + 2l''' = 0$. When the second and third are eclipsed together, then $l'' = l'''$, and consequently $l' - l'' = 180$; hence, when the second and third satellites of Jupiter are eclipsed at the same time, the first is always in conjunction with Jupiter. Various other interesting consequences of this theorem might be easily deduced; but we leave the ingenious reader to make them out for himself. The relative distances of the satellites from their primaries are shown in plate VII. fig. 13.

128. Saturn, when viewed through a good telescope, makes a more remarkable appearance than any of the other planets. Galileo first discovered his uncommon shape, and from the discoveries made by him and other astronomers, it appears that this planet is surrounded by a broad thin ring, the edge of which reflects little, if any, of the sun's light to us, but the planes of the ring reflect the light in the same manner that the planet itself does. If we suppose the diameter of Saturn to be divided into three equal parts, the diameter of the ring is about seven of these parts. The ring is detached from the body of Saturn in such a manner, that the distance between the innermost part of the ring and the body is equal to its breadth. If we had a view of the planet and his ring with our eyes perpendicular to one of the planes of the latter, we should see them as in plate VII. fig. 12; but our eye is never so much elevated above either plane as to have the visual ray at right angles to it, nor indeed is it ever elevated more than about 30° above it; so that the ring being commonly viewed at an oblique angle, appears of an oval form, and through very good telescopes double, as represented, plate VII. fig. 13. and plate XI. fig. 3. When the ring appears most open, its longest diameter appears about twice the length of its shortest.

129. Both the outward and inward rim are projected into an ellipsis, more or less oblong, according to the different degrees of obliquity with which it is viewed. Sometimes our eye is in the plane of the ring, and then it becomes invisible; either because the outward edge is not fitted to reflect the sun's light, or more probably because it is too thin to be seen at such a distance. As the plane of this ring keeps always parallel to itself, that is, its situation in one part of the orbit is always parallel to that in any other part, it disappears twice in every evolution of the planet, that is about once in fifteen years; and the planet sometimes appears quite round for months together. At other times the distance betwixt the body of the planet and the ring is very perceptible; and Mr. Whiston tells us, that Dr. Clarke's father saw a star through the opening.

130. When Saturn appears round, if our eye be in the plane of the ring, it will appear as a dark line across the middle of the planet's disk; and if our eye be elevated above the plane of the ring, a shadowy belt will be visible, caused by the

shadow of the ring as well as by the interposition of part of it betwixt the eye and the planet. The shadow of the ring is broadest when the sun is most elevated, but its obscure parts appear broadest when our eye is most elevated above the plane of it. When it appears double, the ring next the body of the planet appears brightest; when the ring appears of an elliptical form, the parts about the ends of the largest axis are called the ansæ. These, a little before and after the disappearing of the ring, are of unequal magnitude: the largest ansæ is longer visible before the planet's round phase, and appears again sooner than the other. In the diagram, plate VII. fig. 2, are delineated the phases of the ring from its full appearance in 1825, to its disappearance in 1832, and its full re-appearance in 1839.

131. Dr. Herschel has found that the ring is double, or that there are two concentric rings; also that it has a motion of rotation in its own plane, its axis of motion being the same as that of Saturn himself, and its periodical time 10h. 32' 15", 4: But he thinks it probable that the concentric rings may not revolve in the same period. Their dimensions, and the space between them, he states in the following proportion to each other:—

	miles.
Inner diameter of the same ring . . .	146,345
Outside diameter of ditto	184,393
Inner diameter of the larger ring . . .	190,248
Outside diameter of ditto	204,883
Breadth of the ring	20,000
Breadth of the outer ditto	7,200
Breadth of the vacant space	2,839

132. Dr. Herschel concludes, from his observations on the ring, that its structure is such as to allow it to remain permanently in its present state; nor does he think it at all probable that the ring is of that changeable nature which some persons have imagined.

133. The same excellent astronomer, from a series of observations on the belts of Saturn, has concluded, that he revolves upon his axis in 10h. 16' 0", 4, that he has a dense atmosphere, and that his polar diameter is to his equatorial one as 10 to 11.

134. Saturn has, besides his ring, seven little secondary planets or satellites revolving round him. One of them, which till lately was reckoned the fourth in order from Saturn, was discovered by Huygens in 1655, by means of a telescope 100 feet long; and the others, viz. the first, second, third, and fifth, at different times by Cassini, between 1671 and 1684, by the help of glasses of 100 and 136 feet. The sixth and seventh have lately been discovered by Herschel, with his forty feet reflecting telescope, in 1787 and 1788. These he has called the sixth and seventh satellites, though they are nearer to Saturn than the other five; that the names may not be mistaken with regard to former observations of them.

135. The periodical revolutions and distances of these satellites expressed in semidiameters of that planet, and in English miles are as follow

No.	Periodic Times.	Distances in		Angles of Orbs.
		Semi-diam.	Miles.	
1	1d. 21h. 18' 27"	4 $\frac{1}{2}$	170,000	1' 27"
2	2 17 41 22	5 $\frac{1}{2}$	217,000	1 52
3	4 12 25 12	8	303,000	2 36
4	15 22 41 13	18	704,000	6 18
5	79 7 48 0	54	2,050,000	17 4
6	1 8 53 9	3 $\frac{3}{8}$	135,000	1 14
7	0 22 40 46	2 $\frac{3}{8}$	107,000	0 57

136. The first four describe ellipses like those of the ring, and are in the same plane: their inclination to the orbit is from 30° to 31°. The fifth describes an orbit inclined from 17° to 18° to the orbit of Saturn, his plane lying between the ecliptic and those of the other satellites. Dr. Herschel observes, that the fifth satellite turns round its axis once, exactly in the time in which it revolves round the planet Saturn. In this respect, like the satellites of Jupiter, it resembles our moon, which does the same thing. The proportional distances of the seven satellites formerly known to astronomers, are shown in plate VII. fig. 13.

137. The apparent form of the ring of Saturn, and the form of the orbits of his first four satellites, may easily be found by means of the following table:

ARGUMENT.				
Long. of Saturn + 13° 43'.				
Degrees.	Signs.		Signs.	Degrees.
	O. VI.	I. VII.	II. VIII.	
	— +	— +	— 4.

	Signs.	Signs.	Signs.	

138. To find the shape of Saturn's ring by this table, add his longitude to 13° 43', and with the sum as an argument enter the table, the number from which will represent the shorter diameter, the longer diameter being reckoned a thousand. This, however, requires a small correction for the

planet's latitude, which correction is obtained by taking one-fourth of the latitude in minutes, and applying it to the number in the table, with the sign — when the latitude is north, but + when south.

Example. What is the shape of Saturn's ring on January 25, 1826?

By the Nautical Almanack, his longitude, on that day, is 2° 15' 23', and latitude 1° 26' S. Now 2° 15' 23' + 13° 43', is 2° 29' 6', with which, in the table, we find —521, which corrected by + 26, one-fourth of the latitude gives —495; or the shorter diameter is to the longer, as 495 to 1000. The sign + indicates that the most distant half of the ring is north, and — that the most distant half is south of the centre of the planet.

139. The Georgium Sidus, Herschel, or Uranus, was discovered by Herschel on March 13th 1781. From certain inequalities in the motion of Jupiter and Saturn, the existence of a planet of considerable size, without the orbit of either, had before been suspected. Its apparent magnitude, as seen from the earth, is about three seconds and a half; and as, from its distance from the sun, it shines but with a pale light, it cannot often be seen with the naked eye. Its diameter is about four times and a half that of the earth, and it revolves round the sun in 83 years, 150 days, 18 hours. The want of light in this planet, on account of its great distance from the sun, is supplied by no less than six moons, which revolve round it in different periods. But there is a remarkable peculiarity in the position of the orbits in which these moons revolve round their primary, and in the direction in which they revolve in their orbits. The orbits are nearly perpendicular to the plane of the ecliptic, and they revolve in them in a direction contrary to the order of the signs of the ecliptic. La Place, from theoretical considerations, concludes that this planet itself revolves on an axis very little inclined to the plane of the ecliptic; but there is little hope that this theoretical deduction will ever be either confirmed, or set aside, by observations on a body so very remote.

140. The periods of the revolution of the satellites, and the greatest angle of elongation of their orbits, as seen from the earth, are contained in the following table.

Satellite.	Period.			Elongation
	D.	H.	M.	
1	5	21	25	25°5'
2	8	17	1	33°9'
3	10	23	4	38°57'
4	13	11	5	44°22'
5	38	1	49	88°44'
6	107	16	40	176°88'

141. We are unacquainted with any secondary cause that could have any influence in regulating the respective distances of the planets from the sun; but there certainly does exist a relation which, from its singularity, it is difficult to believe quite accidental. This was first ob-

served by professor Bode of Berlin, who remarked, that a planet was wanting at the distance at which the new planets have been discovered, to complete the relation. According to him the distances of the planets may be expressed nearly as follows, the earth's distances from the sun being ten.

Mercury . . .	4	=	4
Venus . . .	4 + 3 × 1	=	7
Earth . . .	4 + 3 × 2	=	10
Mars . . .	4 + 3 × 2 ²	=	16
New Planets . . .	4 + 3 × 2 ³	=	28
Jupiter . . .	4 + 3 × 2 ⁴	=	52
Saturn . . .	4 + 3 × 2 ⁵	=	100
Herschel . . .	4 + 3 × 2 ⁶	=	196

142. The comets, viewed through a telescope, have a very different appearance from any of the planets. The nucleus, or star, seems much dimmer. They are to appearance surrounded with atmospheres of a prodigious size, often rising ten times higher than the nucleus, and have often likewise different phases, like the moon.

143. The head of a comet, seen through a good telescope, appears to consist of a solid globe, and an atmosphere, that surrounds it. The solid part is frequently called the nucleus; which, through a telescope, is easily distinguished from the atmosphere or hairy appearance.

144. A comet is generally attended with a blaze or tail, whereby it is distinguished from a star or planet; as it is also by its motion. Sometimes the tail only of a comet has been visible at a place where the head has been all the while under the horizon; such an appearance is called a beam. Whether the tail of a comet is caused or not by the heat of the sun, it is always observed to grow larger as it approaches, and to diminish as it recedes from that luminary.

145. If the tail were to continue of the same length, it would appear longer or shorter, according to the different views of the spectator; for if his eye be in a line, drawn through the middle of the tail lengthways, or nearly so, the tail will not be distinguished from the rest of the atmosphere, but the whole will appear round; if the eye be a little out of that line, the tail will appear short (see plate VII. fig. 8); and it is called bearded comet, when the tail hangs down towards the horizon, as in that figure. If the tail of a comet be viewed sideways, the whole length of it is seen. It is obvious, that the nearer the eye is to the tail, the greater will be its apparent length.

146. The tails of comets often appear bent (see plate V. fig. 12, 13). This is probably owing to the resistance of the æther; which, though extremely small, may have a sensible effect on so thin a vapour as the tail consists of. This bending is seen only when the earth is not in the plane of the orbit of the comet continued. When that plane passes through the eye of the spectator, the tail appears straight. See plate V. fig. 10, 11.

147. The fixed stars, when viewed through the best telescopes, appear not in the least magnified, but rather diminished, on account, as is thought by some, that the telescope takes off that twinkling appearance they make to the naked eye; but by

others more probably, that the telescope tube excludes a quantity of the rays of light, which are not only emitted from the particular stars themselves, but by many thousands more, which falling upon our eyelids and the aerial particles about us, are reflected into our eyes so strongly as to excite vibrations, not only on those points of the retina where the images of the stars are formed, but also in other points at the same distance round about. This, without the telescope, makes us imagine the stars to be much bigger than when we see them only by a few rays coming directly from them, so as to enter our eye without being intermixed with others.

148. The number of stars appear prodigiously increased through the telescope; seventy stars have been counted in the constellation called Pleiades, and no fewer than 2000 in that of Orion. The late improvements of Herschel, however, have shown the number of stars to be exceedingly beyond even what the discoveries of former astronomers would induce us to suppose. He has also shown that many, which to the eye, or through ordinary glasses, appear single, do in fact consist of two or more stars; and that the galaxy, or milky way, owes its light entirely to multitudes of small stars placed so close, that the naked eye, or even ordinary telescopes, cannot distinguish them.

149. The nebulae, or small whitish specks, discoverable by telescopes in various parts of the heavens, are owing to the same cause. Former astronomers could only reckon 103; but Herschel has discovered upwards of 1250. He has also discovered a species of them, which he calls planetary nebulae, on account of their brightness, and shining with a well-defined disk

SECT. III.—CONCLUSIONS DRAWN FROM THE APPEARANCES OF THE SUN AND PLANETS.

150. There is an appearance in the heavens, termed semita luminosa, or the zodiacal light, which is now generally supposed to be owing to the sun's atmosphere. This was first discovered by Cassini in 1683. It is something like the milky way, a faint twilight, or the tail of a comet, thin enough to let stars be seen through it, and seems to surround the sun in the form of a lens, the plane whereof is nearly co-incident with that of the sun's equator. It is seen stretched along the zodiac, and accompanies the sun in his annual motion through the twelve signs. Each end terminates in an angle of about 21°: the extent of it in length from either of the angular points varies from 50 to 100°; it reaches beyond the orbit of Venus, but not so far as that of the earth. The breadth of it near the horizon is also various; from 12° almost to 30°: near the sun, where it may reasonably be supposed to be broadest, it cannot be seen.

151. This light is weakest in the morning, and strongest at night; disappearing in full moon-light, or in strong twilight, and therefore is not at all visible about midsummer, in places so near either of the poles as to have their twilight all the night, but may be seen in those places, in the middle of winter, both morning and evening, as it may in places under and near the equator, all the year round. In north latitude it is most conspicuous after the evening twilight,

about the latter end of February, and before the morning twilight in the beginning of October; for at those times it stands most erect above the horizon, and is therefore clearest from the thick vapours of the twilight. Besides the difference of real extension of this light in length and breadth at different times, it is diminished by the nearness of any other light in the sky; not to mention, that the extent of it will be differently determined by different spectators, according to the goodness of their eyes.

152. Cassini supposed that, as by the rotation of the sun, some gross parts are thrown up on his surface, whereof spots and nebulosities are formed; so the great rapidity wherewith the equatorial parts are moved, may throw out, to a considerable distance, a number of particles of a much finer texture, of sufficient density to reflect light. That this light was caused by an emanation from the sun, similar to that of the spots, he thought probable from the following observation: That after the year 1688, when this light began to grow weaker, no spots appeared upon the sun; whereas, in the preceding years, they were frequently seen there; and that the great inequality in the intervals between the times of the appearances of the solar spots, has some analogy to the irregular returns of weakness and strength in this light, in like circumstances of the constitution of the air, and of the darkness of the sky. But the atmosphere of no planet can extend beyond the point at which the centrifugal force arising from its evolution is equal to the force of gravity, and that distance is equal to the radius of a planet's orbit, which revolves in the same time that the sun revolves on his axis. Now the sun revolves in about 25 days, and Mercury in about eighty-eight, therefore the solar atmosphere can never extend to the orbit of Mercury, while the zodiacal light, whatever it is, certainly extends much farther. This consideration certainly militates strongly against the hypothesis of the zodiacal light being connected with the solar atmosphere.

153. He was also of opinion that this light in the zodiac, as it is subject to great increase at one time and diminution at another, may sometimes become quite imperceptible; and thought this was the case in 1665, 1672, and 1681, when he saw nothing of it, though he surveyed with great attention those parts of the heavens where, according to his theory, it must have appeared, if it had been as visible then as it was in others. He cites also passages out of several authors, both ancient and modern, which make it probable that it had been seen, both in former and latter ages, but without being sufficiently attended to, or its nature enquired into.

154. As to the solar spots, Dr. Long informs us, that 'they do not change their places upon the sun, but adhere to his surface, or float in his atmosphere, very near his body: and if there be twenty spots upon him at a time, they all keep in the same situation with respect to one another; and, as long as they last, are carried round in the same manner; by the motion of the spots therefore we learn, what we should not otherwise have known, that the sun is a globe, and has a rotation on his axis.'

155. Notwithstanding this, he tells us afterwards, 'The spots, generally speaking, may be said to adhere to the sun, or to be so near him as to be carried round upon him uniformly; nevertheless sometimes, though rarely, a spot has been seen to move with a velocity a little different from the rest; spots that were different parallels, have appeared to be carried along, not keeping always the same distance, but approaching nearer to each other; and when two spots moved in the same parallel, the hindmost has been observed to overtake and pass by the other. The revolution of spots near the equator of the sun, is shorter than of those that are more distant from it.' The apparent change of shape in the spots, as they approach the circumference of the disk, according to this author, is likewise a proof of the sun's rotation round his axis, and that they either adhere to the surface of the luminary, or are carried round his atmosphere very near his surface.

156. The time of the apparent revolution of a spot being known, the true time of its going round upon the sun may be thus found: In plate VII. fig. 3. the arc AC , which, in the month of May, the earth goes through in her orbit in 27 days 12 hours and 20 minutes, is $26^{\circ} 22'$; the arc ac being equal to AC : the apparent revolution of a spot is the whole circle $abcd$, or 360° with the addition of the arc ac of $26^{\circ} 22'$, which makes $386^{\circ} 22'$: then say, as $386^{\circ} 22'$ is to 27 d. 12 h. 20'; so is 360° to 25 d. 15 h. 16'; the true time of the rotation of the sun as it would be seen from a fixed star.

157. The angle of intersection of the sun's equator with the ecliptic is but small, being never more, according to Scheiner, than 8° , nor less than 6° ; for which reason he settled it at 7° though Cassini makes it $7\frac{1}{2}$. This plane continued cuts the ecliptic in two opposite points, which are called the sun's nodes, being 10° of Π , and 10° of φ ; and two points in the ecliptic, 90° from the nodes, may be called the limits. These are 10° of III and 10° of X . When the earth is in either of these nodes, the equator of the sun, if visible, would appear as a straight line; and, by reason of the vast distance of the sun from us, all his parallels would likewise appear as straight lines; but, in every other situation of the earth, the equator and parallels of the sun would, if visible, appear as ellipses growing wider the farther the earth is from the nodes, and widest of all when the earth is in one of her limits.

158. There has been no small speculation respecting the nature and formation of the solar spots. Some have thought that the sun is an opaque body, mountainous and uneven as our earth is, covered all over with a fiery and luminous fluid; that this fluid is subject to ebbing and flowing, after the manner of our tides, so as sometimes to leave uncovered the tops of rocks or hills, which appear like black spots; and that the nebulosities about them are caused by a kind of froth. Others have imagined that the fluid which sends us so much light and heat, contains a nucleus or solid globe, wherein are several volcanoes, which, like *Ætna* or *Vesuvius*, from time to time cast up quantities of bituminous matter to the surface of the sun, and form those spots which are

seen thereon; and that, as this matter is gradually consumed by the luminous fluid, the spots disappear for a time, but are seen to rise again in the same places when these volcanoes cast up new matter. A third opinion is, that the sun consists of a fiery luminous fluid, wherein are immersed several opaque bodies of irregular shapes; and that these bodies, by the rapid motion of the sun, are sometimes buoyed or raised up to the surface, where they form the appearance of spots, which seem to change their shapes according as different sides of them are presented to the view. A fourth opinion is, that the sun consists of a fluid in continual agitation; that, by the rapid motion of this fluid, some parts more gross than the rest are carried up to the surface of the luminary, like the scum of melted metal rising up to the top in a furnace; that these scums, as they are differently agitated by the motion of the fluid, form themselves into those spots we see on the solar disk; and, besides the optical changes already mentioned, grow larger, are diminished in their apparent magnitude, recede a little from, or approach nearer to, each other, and are at last entirely dissipated by the continual rapid motion of the fluid, or are otherwise consumed or absorbed.

159. Dr. Wilson, in the sixty-fourth volume of the Philosophical Transactions, advances a new opinion, viz. that they are hollows in the surface of the luminary. On this supposition he offers some queries and conjectures concerning the nature of the sun himself. He asks, Whether it is not reasonable to think, that the vast body of the sun is made up of two kinds of matter very different in their qualities; that by far the greatest part is solid and dark; and that this dark globe is encompassed with a thin covering of that resplendant substance, from which the sun would seem to derive the whole of his vivifying heat and energy?

160. This, if granted, will afford a satisfactory solution of the appearance of spots; because, if any part of this resplendant surface shall be by any means displaced, the dark globe must necessarily appear; the bottom of the cavity corresponding to the nucleus, and the shelving sides to the umbræ. The shining substance, he thinks, may be displaced by the action of some elastic vapour generated within the substance of the dark globe. This vapour swelling into such a volume as to reach up to the surface of the luminous matter, would thereby throw it aside in all directions: and as we cannot expect any regularity in the production of such a vapour, the irregular appearance and disappearance of the spots is by that means accounted for; as the reflux of the luminous matter must always occasion the dark nucleus gradually to decrease, till at last it becomes indistinguishable from the rest of the surface.

161. But an objection occurs, that, on this supposition, the nucleus of a spot, whilst on the decrease, should always appear nearly circular, by the gradual descent of the luminous matter from all sides to cover it. To this Dr. Wilson replies, that in all probability the surface of the dark globe is very uneven and mountainous,

which prevents the regular reflux of the shining matter; and this, he thinks, is rendered very probable by the enormous mountains and cavities which are observed on the moon; and why, says he, may there not be the same on the surface of the sun? He thinks his hypothesis also confirmed by the dividing of the nucleus into several parts, which might arise from the luminous matter flowing in different channels in the bottom of the hollow.

162. The appearance of the umbræ after the nucleus is gone, he thinks, may be owing to a cavity remaining in the luminous matter, though the dark globe is entirely covered. As to a motion of the spots, distinct from what they are supposed to receive from the rotation of the sun round his axis, he says he never could observe any, except what might be attributed to the enlargement or diminution of them when in the neighbourhood of one another. 'But,' says he, 'what would farther contribute towards forming a judgment of this kind, is the apparent alteration of the relative place, which must arise from the motion across the disk on a spherical surface; a circumstance which I am uncertain if it has been sufficiently attended to.'

163. Dr. Wilson's hypothesis is further confirmed by the disappearance of the umbræ on the sides of spots contiguous to one another; as the action of the elastic vapour must necessarily drive the luminous matter away from each, and thus as it were accumulate it between them, so that no umbræ can be perceived. As to the luminous matter itself, he conjectures, that it cannot be any very ponderous fluid, but that it rather resembles a dense fog which broods on the surface of the sun's dark body.

164. Dr. Wilson's general conclusion is, that, 'According to the view of things given in the foregoing queries, there would seem to be something very extraordinary in the dark and unignited state of the great internal spot of the sun. Does not this, (he asks), seem to indicate that the luminous matter that encompasses it derives not its splendor from any intensity of heat? For, if this were the case, would not the parts underneath, which would be perpetually in contact with that glowing matter, be heated to such a degree as to become luminous and bright? At the same time it must be confessed, that although the internal globe was in reality much ignited, yet when any part of it forming the nucleus of a spot is exposed to our view, and is seen in competition with a substance of such amazing splendor, it is no wonder that an inferior degree of light, should in these cases, be unperceivable.'

165. As to the moon, it is allowed on all hands, that there are prodigious inequalities on her surface. This is proved by looking at her through a telescope, at any other time than when she is full; for then there is no regular line bounding light and darkness; but the confines of these parts appear as it were toothed and cut with innumerable notches and breaks; and even in the dark part, near the borders of the lucid surface, there are seen some small spaces enlightened by the sun's beams. Upon the fourth day after new moon, there may be perceived some shining points like rocks or small islands within the dark

body of the moon; and not far from the confines of light and darkness, there are observed other little spaces which join to the enlightened surface, but run out into the dark side, which by degrees change their figure, till at last they come wholly within the illuminated space, and have no dark parts round them at all. Afterwards many more shining spaces are observed to arise by degrees, and to appear within the dark side of the moon, which, before they drew near to the confines of light and darkness, were invisible, being without any light, and totally immersed in the shadow. The contrary is observed in the decreasing phases, where the lucid spaces which joined the illuminated surface by degrees recede from it; and, after they are quite separated from the confines of light and darkness, remain for some time visible, till at last they also disappear. Now it is impossible that this should be the case, unless these shining points were higher than the rest of the surface, so that the light of the sun may reach them.

166. Astronomers have endeavoured to measure the height of these lunar mountains, in the following manner. Let ECD , Plate VII. fig. 6, be the hemisphere of the moon illuminated by the sun; ECD the diameter of the circle bounding light and darkness, and A the top of a hill within the dark part when it first begins to be illuminated. Observe with a telescope the proportion of the right line AE , or the distance of the point A from the lucid surface to the diameter of the moon ED ; and because in this case the ray of light ES touches the globe of the moon, AEC will be a right angle, and therefore in the triangle AEC having the two sides AE and EC , we can find the third side AC ; from which deducting BC or EC , there will remain AB the height of the mountain. By this mode of measuring, which would be just if the line AE could be taken accurately, the height of St. Catherine would be nearly $8\frac{1}{2}$ miles, if according to Riccioli its top was about a sixteenth part of the moon's diameter distant from the confines of the lucid surface. But by the more accurate observations and just calculations of Herschel, this disproportionate height appears to be ill founded, and the generality of the lunar mountains do not exceed half a mile in perpendicular elevation. He thus calculates their heights: Let SLM or slm , fig. 1, be a line drawn from the sun to the mountain, touching the moon at L or l , and the mountain at M or m . Then, to an observer at E or e , the lines LM , lm , will not appear of the same length, though the mountain should be of an equal height; for LM will be projected into on , and lm into ON . But these are the quantities that are taken by the micrometer when we observe a mountain to project from the line of illumination. From the observed quantity on , when the moon is not in her quadrature, to find LM , we have the following analogy. The triangles oOL , rML are similar; therefore $Lo : LO :: Lr : LM$, or $\frac{L \cdot O \times on}{L \cdot o} = LM$: but LO is the radius of the moon, and Lr or on is the observed distance of the mountain's projection; and Lo is the sine of the angle $ROL = oLS$; which we may take to be the distance of the sun from the moon with-

out any material error, and which therefore we may find at any given time from an ephemeris.

167. Some modern astronomers have discovered a still greater similarity between the lunar mountains and those of our earth; viz. that some of them are really volcanoes, and emit fire, as ours do. An appearance of this kind was discovered some years ago by Ulloa, in an eclipse of the sun. It was a small bright spot like a star near the margin of the moon, and which he at that time supposed to have been a hole with the sun's light shining through it. Succeeding observations, however, have induced astronomers to attribute appearances of this kind to the eruption of volcanic fire: and Herschel has particularly observed several eruptions of the lunar volcanoes, and similar appearances have been more recently noticed by that acute and accurate observer, captain Henry Kater.

168. Many conjectures have been formed respecting the nature of the moon's substance; some have imagined, that, besides the light reflected from the sun, the moon has also some obscure light of her own, by which she would be visible without being illuminated by the sun-beams. In proof of this it is urged, that during the time of even total eclipses the moon is still visible, appearing of a dull red color, as if obscured by a great deal of smoke. In reply to this, it has been advanced, that this is not always the case; the moon sometimes disappearing totally in the time of an eclipse, so as not to be discernible by the best glasses, while little stars of the fifth and sixth magnitudes were distinctly seen as usual; and when the moon is visible in a total eclipse, a sufficient reason may be assigned for this appearance from the refraction of the sun's rays through our atmosphere, which are reflected back to the earth by the otherwise dark surface of the moon.

169. Various speculations have also been indulged concerning the spots on the moon's surface. Some philosophers have been so taken with the beauty of the brightest places observed in her disk, that they have imagined them to be rocks of diamonds; and others have compared them to pearls and precious stones. Keill, and the greater part of astronomers are now of opinion, that these are only the tops of mountains, which, by reason of their elevation, are more capable of reflecting the sun's light than others which are lower. The dusky spots, he says, cannot be seas, nor any thing of a liquid substance; because, when examined by the telescope, they appear to consist of an infinity of caverns and empty pits, whose shadows fall within them, which can never be the case with seas, or any liquid substance; but even within these spots, brighter places are also to be observed; which, according to his hypothesis, ought to be the points of rocks standing up within the cavities.

170. The existence of the lunar atmosphere, so long a subject of controversy, is now decidedly set at rest. Schroeter of Lillenthal has observed phenomena precisely analogous to the twilight, and which can in no way be accounted for independently of atmospheric refraction. He has also, as he says, observed several obscurtions, and returning serenity, and other changes in the lunar atmosphere. In the occultation of

Jupiter by the moon on April 5th, 1824. Mr. Ramage of Aberdeen, and Captain John Ross, R. N. at Stranraer, with each one of Mr. Ramage's splendid reflecting telescopes, observed the disk of Jupiter to be decidedly distorted at the time of its approach to the edge of the moon; and precisely similar appearances were noticed by Mr. Comfield of Northampton, and Mr. Wallis, lecturer on astronomy, on the occultation of Saturn by the moon, on October 30th, 1825.

This question, therefore, having been settled by the most satisfactory of all tests, we deem it unnecessary to enter into the arguments which were wont to be advanced on either side of the question, before sufficient data were obtained for determining it in any way.

171. It has been a question whether the moon and other planets are inhabited. The answers given to it in the negative depend on the position, that human beings could not exist in any of the planets on account of their distance from the sun, and consequent inequality of heat to that which the inhabitants of the earth experience; and the want of an atmosphere in the moon, or the rarity of it, would as effectually preclude that body from being a fit habitation for man. But in reply it is argued, and with reason, that the same power which could make the earth a fit habitation for the animals upon it, could also adapt the organs of other animals to their various situations in the planets; and as the earth teems with life of all kinds, it is probable, that, as there is so great an analogy between it and the planets in other respects, the same analogy prevails with respect to life and inhabitants.

SECT. IV. CONJECTURES AND CONCLUSIONS RESPECTING COMETS.

172. None of the celestial bodies have given rise to more speculation and conjecture than comets. Their strange appearance has in all ages been a matter of terror to the vulgar, who uniformly have looked upon them as bad omens, and forerunners of war, pestilence, &c. Others, less superstitious, supposed them to be meteors raised in the higher regions of the air.

Some part of the modern doctrine concerning them, however, was received in the ancient Italic and Pythagorean schools; for they held them to be so much of the nature of planets that they had their periodical times of appearing; that they were out of sight for a long time, while they were carried aloft at an immense distance from the earth, but became visible when they descended into the lower regions of the air, and thus were nearer to us.

It would be as endless as useless to detail the various conjectures which in the dark ages were formed respecting the nature of comets; and the various extravagant postulata by which each theorist sought to reconcile their appearances with his explanation. Aristotle conceived them to be meteoric bodies; Kepler huge animals, that swam round the sun like fishes; and Bodin imagined that they are spirits, which, having long dwelt on the earth, are about to be translated to the skies.

A celebrated comet, however, which appeared

in 1577, enabled Tycho Brahe to determine that, at any rate, these bodies were at an immense distance; as from many careful observations he found that that comet had no sensible diurnal parallax; and Kepler discovered, from his own observations and those of his master, Tycho, that the comets did not, as had been supposed, move in straight lines, but in paths concave towards the sun, and he conceived that their orbits were parabolas.

At length, from observations made on the great comet of 1680, Sir Isaac Newton found that these bodies, like the planets, move round the sun in elliptical orbits. This comet was seen for twenty-one days in its passage towards the sun, and for nearly three months as it receded from that luminary. The most careful observations were made to determine its place, and the conclusions deduced from these observations are confirmed by observations made on all that have been well-observed since.

173. It has been remarked that a greater number of comets are seen towards the sun than in the opposite hemisphere; the reason of which will easily appear from fig. 9, plate VII. wherein S represents the sun, E the earth, A B C D the sphere of the fixed stars; and because comets neither reflect light enough to be visible, nor emit tails conspicuous enough to attract our notice, till they come within the planetary regions, commonly a good way within the sphere of Jupiter; let K L M N be a sphere concentric to the sun, at such a distance from him, that no comet can be seen by us till it come within that distance: through E draw the plane B D perpendicular to S E, which will divide the sphere K L M N into two hemispheres, one of which, B C D, is towards the sun, the other D A B, opposite. Now it is manifest, that the spherical portion L M N, which is in the hemisphere B C D towards the sun, is larger than the portion N K L in the hemisphere opposite to him; and consequently a greater number of comets will appear in the hemisphere B C D than in that marked D A B.

174. Although the orbs of all comets are very eccentric ellipses, there are vast differences among them. Excepting Mercury and Pallas, there are no great differences among the planets either as to the eccentricity of their orbits, or the inclination of their planes; but the planes of some comets are almost perpendicular to others, and some of their ellipses are much wider than others. The narrowest ellipsis of any comet hitherto observed was that of 1680. There is also a much greater inequality in the motion of the comets than of the planets; the velocity of the former being incomparably greater in their perihelion than in their aphelion; but the planets are but very little accelerated.

175. There is now no question among astronomers, that comets are opaque bodies enlightened by the sun. Their perihelion distances from the sun are exceedingly various, some being not more than one-fifth, and others upwards of four-times the mean distance of the earth. Their diameters too differ very greatly. Their apparent diameters of course vary with their distance; and some have supposed that those apparently preternatural darknesses, of

which several are recorded in history, may have been caused by the interposition of a comet between the earth and the sun, at a time when, from its proximity to the earth, its apparent diameter was greater than the sun's, and when its apparent motion was in the same direction as the sun's. The diameter of the comet of 1744, when at the distance of the sun from us, was about one minute, hence its real diameter was about three times that of the earth. The diameter of their atmosphere is however often ten or fifteen times as great as that of the nucleus.

176. The tails of comets have given rise to various conjectures; but though it is apparent that they are in some way connected with the sun, we know as yet absolutely nothing of either their cause, or their uses. Perhaps the most rational conjecture that has been made respecting them is that of Euler, who imagines that on a comet's approaching the sun the impulse of the solar rays may drive the finer particles of the comet's atmosphere in a direction of course opposite to the sun, and that these particles become visible in the shape of a tail, which, from the resistance it may meet with moving obliquely through the æther, may put on that curved appearance which the tails are often observed to assume. If this hypothesis were true, we might conceive that the velocity of a comet may be so great, that a tail may be produced opposite to the sun before the previously formed one can overtake it. This agrees with what is recorded of the comet of 1744, which is said to have had several tails when near its perihelion.

177. Mr. Whiston has conjectured that the deluge, of which, in the sacred writings, we have the only authentic record, but of which the annals of most nations have traditionary accounts, was produced by the near approach of a comet, whose atmosphere had been attracted by the earth; and he further surmises, that the final catastrophe foretold in the scriptures may be produced by the approach of a comet prodigiously heated in its perihelion. We pretend not, however, on such subjects as these, to penetrate the secrets of Almighty wisdom, which can produce its own ends, by means of which we have no conception.

178. On looking over the catalogue of ancient comets, Dr. Halley found that there was considerable similarity in the elements of the orbits, and in the periodic times of three, which appeared in 1531, 1607, and 1692; and he strongly surmised that these three comets had only been several returns of the same comet, which might be expected to return again about the end of 1758 or the beginning of 1759. Clairault applied himself with great diligence and success to the investigation of the elements of these comets, which he too concluded to be the same; and he predicted that it would be in perihelion on April 13th, 1759, and it actually was in its perihelion on the 13th of March, differing about a month from the predicted time. This comet may be seen in Feb. in 1758.

179. Clairault found, by applying the principles of gravities to the computation of this comet's orbit, that its distance from the sun was lengthened about 600 miles by the attraction of Saturn, and about 518

days by that of Jupiter. And, as we know not how the orbits of these eccentric bodies may be affected by their mutual attractions among themselves, it is probable that many ages will elapse before any very accurate knowledge of the periodic times of many of them will be obtained. Much attention however is at present paid to this branch of astronomy; and, the consequence has been, that a visit of a comet to our regions is found to be an event of very frequent occurrence. In the year 1825 not less than five different comets were observed.

180. The Astronomical Society of London, at their anniversary in February 1824, voted a gold medal to M. Rumker, for his re-discovery of a comet, which was first discovered by M. Guke, and has been called by his name. This comet had been seen, in an intervening return in 1818, by M. Pons, and the astronomical society voted him a silver medal as a token of their approbation of the industry and talent with which he has applied to this interesting branch of the science.

In connexion with this subject too, we cannot help noticing a most profound and ingenious paper by M. Masotti, on the resistance of æther, as deduced from the irregularities of the motion of Guke's comet.

SECT. V.—CONJECTURES AND CONCLUSIONS RESPECTING THE FIXED STARS.

181. Astronomers have supposed the innumerable multitude of fixed stars to be so many suns, each of which is attended by a certain number of planets or habitable worlds like our own, as well as visited by comets. The strongest argument for this hypothesis is, that the stars cannot be magnified by a telescope on account of their immense distance; whence it is concluded that they shine by their own light, and are therefore so many suns; each of which we may suppose to be equal, if not superior, in lustre and magnitude to our own. They are not supposed to be at equal distances from us, but to be more remote in proportion to their apparent smallness. This supposition is necessary to prevent any interference of their planets, and thus there may be as great a distance between a star of the first magnitude and one of the second, apparently close to it, as between the earth and the fixed stars first mentioned.

182. Others object, that the disappearance of some of the fixed stars is a demonstration that they cannot be suns, as it would be in the highest degree absurd to think that God would create a sun which might disappear of a sudden, and leave its planets and their inhabitants in endless night. But this argument will have no weight with those who believe in the doctrines of revelation; which assures us that our world will come to an end, and that our sun will be deprived of his light; and consequently that all the planets which circulate around him will be involved in darkness.

183. In short, there is nothing inconsistent with either scripture or reason in supposing, that while infinite space is universally filled with illuminating suns and circulating planets, each world, or rather each solar system of worlds, has

its own periods of creation, duration, and final consummation; as we are assured ours had, and will have. And the discoveries of astronomers respecting old stars disappearing, and new ones being observed, are perfectly consistent with the doctrines of creation and dissolution, which all Christians profess to believe, with regard to our own solar system and the globe we inhabit.

184. Some, however, have thought that the variable stars which disappear for a time, are planets, which are only visible during some part of their course. But this their apparent immobility, notwithstanding their decrease of lustre, will not allow us to think. Some have imagined that one side of them may be naturally much darker than the other, and when by the revolution of the star upon its axis, the dark side is turned towards us, the star becomes invisible, and for the same reason, after some interval, resumes its former lustre.

185. M. Maupertuis is of opinion that some stars, by their prodigiously quick rotations on their axes, may not only assume the figures of oblate spheroids, but that by the great centrifugal force arising from such rotations, they may become of the figures of mill-stones, or be reduced to flat circular planes, so thin as to be quite invisible when their edges are turned towards us; as Saturn's ring is in such positions. But when very eccentric planets or comets go round any flat star, in orbits much inclined to its equator, the attraction of the planets or comets in their perihelions must alter the inclination of the axis of that star; on which account it will appear more or less large and luminous, as its broad side is more or less turned towards us. And thus he imagines we may account for the apparent changes of magnitude and lustre in those stars, and likewise for their appearing and disappearing.

186. In the Philosophical Transactions for 1783, Mr. Mitchell, in proposing a method of determining the distance, magnitude, &c. of the fixed stars, by the diminution of the velocity of their light, should any such thing be discovered, supposes that by far the greater part, if not all of them, are systems of stars so near each other, as probably to be liable to be affected sensibly by their mutual gravitation; and that it is therefore not unlikely that the periods of the revolutions of some of these about their principals (the smaller ones being upon this hypothesis to be considered as satellites to the others), may some time or other be discovered. And the recent observations of Mr. Herschel and Mr. South on double stars, when compared with those made by Sir William Herschel many years ago, show decidedly that many of these double stars do certainly revolve round each other.

187. Herschel, improving on Mitchell's idea of the fixed stars being collected into groups, and assisted by his own observations with the extraordinary telescopic powers already mentioned, has suggested a theory concerning the construction of the universe entirely new and singular. It had been the opinion of former astronomers, that our sun, besides occupying the centre of the system which properly belongs to him, occu-

pled also the centre of the universe: but Herschel is of a different opinion.

188. The observations on which this theory is founded, were made with a Newtonian reflector of twenty feet focal length, and an aperture of eighteen inches. With this powerful telescope he first began to survey the Via Lactea, and found that it completely resolved the whitish appearance into stars, which the telescopes he formerly used had not light enough to do. The portion he first observed was that about the hand and club of Orion; in which he found an astonishing multitude of stars, whose number he endeavoured to estimate by counting many fields (or apparent spaces of the heavens, which he could see at once through his telescope), and computing from a medium of these how many might be contained in a given portion of the milky way. In the most vacant place to be met with in that neighbourhood, he found 63 stars; other six fields contained 110, 60, 70, 90, 70, and 74 stars; a medium of all which gave 79 for the number of stars to each field. Thus he found that by allowing 15' for the diameter of his field of view, a belt of 15° long and 2° broad, which he had often seen pass before his telescope in an hour's time, could not contain less than 50,000 stars, large enough to be distinctly numbered: besides which he suspected twice as many more, which could be seen only now and then by faint glimpses, for want of sufficient light.

189. The doctor's success within the milky way soon induced him to turn his telescope to the nebulous parts of the heavens, of which an accurate list had been published in the *Connaissance des Temps* for 1783 and 1784. Most of these yielded to a Newtonian reflector of twenty feet focal distance, and twelve inches aperture; which plainly discovered them to be composed of stars, or at least to contain stars, and to show every other indication that they consisted of them entirely.

190. 'The nebulae,' says he, 'are arranged into strata, and run on to a great length; and some of them I have been able to pursue, and to guess pretty well at their form and direction. It is probable enough that they may surround the whole starry sphere of the heavens not unlike the milky way, which undoubtedly is nothing but a stratum of fixed stars; and as this latter immense starry bed is not of equal breadth or lustre in every part, nor runs on in one straight direction, but is curved, and even divided into two streams along a very considerable portion of it, we may likewise expect the greatest variety in the strata of the clusters of stars and nebulae.'

191. 'One of these nebulous beds is so rich, that in passing through a section of it in the time of only thirty-six minutes, I have detected not less than thirty-one nebulae, all distinctly visible upon a fine blue sky. Their situation and shape, as well as condition, seem to denote the greatest variety imaginable. In another stratum, or perhaps a different branch of the former, I have often seen double and treble nebulae variously arranged; large ones with small seeming attendants; narrow, but much extended lucid nebulae or bright dashes; some of the shape of a fan, resembling an electric brush issuing from

a lucid point; others of the cometic shape, with a seeming nucleus in the centre, or like cloudy stars, surrounded with a nebulous atmosphere; a different sort again contain a nebulosity of the milky kind, like that wonderful inexplicable phenomenon about θ Orionis; while others shine with a fainter mottled kind of light, which denotes their being resolvable into stars.

192. 'It is very probable that the great stratum called the milky way, is that in which the sun is placed, though perhaps not in the very centre of its thickness. We gather this from the appearance of the galaxy, which seems to encompass the whole heavens, as it certainly must do if the sun is within the same. For suppose a number of stars arranged between two parallel planes, indefinitely extended every way, but at a given considerable distance from one another, and calling this a sidereal stratum; an eye placed somewhere within it will see all the stars in the direction of the planes of the stratum projected into a great circle, which will appear void on account of the accumulation of the stars, while the rest of the heavens at the sides will only seem to be scattered over with constellations, more or less crowded according to the distance of the planes, or number of stars contained in the thickness or sides of the stratum.

193. 'From appearances,' Dr. Herschel continues, 'we may infer that the sun is most likely placed in one of the great strata of the fixed stars, and very probably not far from the place where some smaller stratum branches out from it. This supposition will satisfactorily, and with great simplicity, account for all the phenomena of the milky way; which, according to this hypothesis, is no other than the appearance of the projection of the stars contained in this stratum and its secondary branch. As a farther inducement to look on the galaxy in this point of view, let it be considered that we can no longer doubt of its whitish appearance arising from the mixed lustre of the numberless stars that compose it. Now should we suppose it to be an irregular ring of stars, in the centre nearly of which we must then suppose the sun to be placed, it will appear not a little extraordinary that the sun, being a fixed star like those which compose this imagined ring, should just be in the centre of such a multitude of celestial bodies, without any apparent reason for this singular distinction; whereas, on our supposition, every star in this stratum, not very near the termination of its length or height, will be so placed as also to have its own galaxy, with only such variations in the form and lustre of it as may arise from the particular situation of each star.'

194. A continued series of observations confirmed Dr. Herschel in these opinions; and in a succeeding paper he has given a sketch of his ideas of the interior construction of the heavens: 'That the milky way,' says he, 'is a most extensive stratum of stars of various sizes, admits no longer of the least doubt; and that our sun is one of the heavenly bodies belonging to it is as evident. I have now viewed and gauged this shining zone in almost every direction, and find it composed of shining stars, whose number, by

the account of those gauges, constantly increases and decreases in proportion to its apparent brightness to the naked eye.

195. 'But, in order to develop the ideas of the universe that have been suggested by my late observations, it will be best to take the subject from a point of view at a considerable distance both of space and time. Let us then suppose numberless stars of various sizes scattered over an indefinite portion of space, in such a manner as to be almost equally distributed through the whole. The laws of attraction, which no doubt extend to the remotest regions of the fixed stars, will operate in such a manner as most probably to produce the following remarkable effects:

196. 1. It will frequently happen that a star, being considerably larger than its neighbouring ones, will attract them more than they will be attracted by others that are immediately around them; by which means they will be in time as it were condensed about a centre; or in other words, form themselves into a cluster of stars of almost a globular figure, more or less regularly so, according to the size and original distance of the surrounding stars. The perturbations of the mutual attractions must undoubtedly be very intricate, as we may easily comprehend, by considering what Sir Isaac Newton has said (Princip. lib. i. prob. 38, et seq.): but in order to apply this great author's reasoning, of bodies moving in ellipses, to such as are here for a while supposed to have no other motion than what their mutual gravity has imparted to them, we must suppose the conjugate axes of these ellipses indefinitely diminished, whereby the ellipses will become straight lines.

197. 2. The next case, which will happen almost as frequently as the former, is where a few stars, though not superior in size to the rest, may chance to be rather nearer each other than the surrounding ones; for here also will be formed a prevailing attraction in the combined centre of gravity of them all, which will occasion the neighbouring stars to draw together; not, indeed, so as to form a regular globular figure, but, however, in such a manner as to be condensed towards the common centre of gravity of the whole irregular cluster. And this construction admits of the utmost variety of shapes, according to the number and situation of the stars which first gave rise to the condensation of the rest.

198. 3. From the composition and repeated conjunction of both the foregoing forms, a third may be derived, when many large stars, or combined small ones, are situated in long extended regular or crooked rows, hooks, or branches; for they will also draw the surrounding ones so as to produce figures of condensed stars coarsely similar to the former, which gave rise to these condensations.

199. 4. We may likewise admit of still more extensive combinations; when, at the same time that a cluster of stars is forming in one part of space, there may be another collecting in a different, but perhaps not far distant, quarter, which may occasion a mutual approach towards their common centre of gravity.

200. 5. In the last place, as a natural consequence of the former cases, there will be great cavities or vacancies formed by the retreat of the stars towards the various centres which attract them; so that, upon the whole, there is evidently a field of the greatest variety for the mutual and combined attractions of the heavenly bodies to exert themselves in.

201. From this theoretical view of the heavens, which has been taken from a point not less distant in time than in space, we will now retreat to our own retired station, in one of the planets attending a star in its great combination with numberless others; and in order to investigate what will be the appearances from this contracted situation, let us begin with the naked eye. The stars of the first magnitude, being in all probability the nearest, will furnish us with a step to begin our scale. Setting off, therefore, with the distance of Sirius or Arcturus, for instance, as unity, we will at present suppose, that those of the second magnitude are at double, those of the third at treble, the distance, &c. Taking it for granted, then, that a star of the seventh magnitude (the smallest supposed visible with the naked eye) is about seven times as far as one of the first, it follows, that an observer who is enclosed in a globular cluster of stars, and not far from the centre, will never be able with the naked eye to see to the end of it; for since, according to the above estimations, he can only extend his view to above seven times the distance of Sirius, it cannot be expected that his eyes should reach the borders of a cluster which has perhaps not less than fifty stars in depth everywhere around him. The whole universe to him, therefore, will be comprised in a set of constellations richly ornamented with scattered stars of all sizes: or, if the united brightness of a neighbouring cluster of stars should, in a remarkably clear night, reach his sight, it will put on the appearance of a small, faint, whitish, nebulous cloud, not to be perceived without the greatest attention.

202. Let us suppose him placed in a much extended stratum, or branching cluster of millions of stars, such as may fall under the third form of nebulae already considered. Here also the heavens will not only be richly scattered over with brilliant, constellations, but a shining zone or milky way will be perceived to surround the whole sphere of the heavens, owing to the combined light of those stars which are too small, that is, too remote to be seen. Our observer's sight will be so confined, that he will imagine this single collection of stars, though he does not even perceive the 1000th part of them, to be the whole contents of the heavens.

203. Allowing him now the use of a common telescope, he begins to suspect, that all the milkiness of the bright path which surrounds the sphere may be owing to stars. He perceives a few clusters of them in various parts of the heavens, and finds also that there are kinds of nebulous patches: but still his views are not extended to reach so far as to the end of the stratum in which he is situated; so that he looks upon these patches as belonging to that system, which to him seems to comprehend every celestial object. He now increases his power of

vision; and, applying himself to a close observation, finds that the milky way is indeed no other than a collection of very small stars. He perceives, that those objects which had been called nebulae, are evidently nothing but clusters of stars. Their number increases upon him; and when he resolves one nebula into stars, he discovers ten new ones which he cannot resolve. He then forms the idea of immense strata of fixed stars, of clusters of stars, and of nebulae; till going on with such interesting observations, he now perceives, that all these appearances must naturally arise from the confined situation in which we are placed. Confined it may justly be called, though in no less a space than what appeared before to be the whole region of the fixed stars, but which now has assumed the shape of a crookedly branching nebula; not indeed one of the least, but perhaps very far from being the most considerable, of those numberless clusters that enter into the construction of the heavens.

204. Dr. Herschel shows, that this theoretical view of the heavens is perfectly consistent with facts, and seems to be confirmed by a series of observations. 'Upon the whole,' says he, 'I believe it will be found, that the foregoing theoretical view, with all its consequential appearances, as seen by an eye enclosed in one of the nebulae, is no other than a drawing from nature, wherein the features of the original have been closely copied: and I hope the resemblance will not be called a bad one, when it shall be considered how very limited must be the pencil of an inhabitant of so small and retired a portion of an indefinite system, in attempting the picture of so unbounded an extent.'

205. The doctor having determined that the visible system of nature, by us called the universe, consisting of all the celestial bodies, and many more than can be seen by the naked eye, is only a group of stars or suns with their planets, constituting one of those patches called a nebula, and perhaps not one 10,000th part of what is really the universe, he goes on to delineate the figure of this vast nebula, which he is of opinion may now be done; and for this purpose, he gives a table, calculating the distance of the stars which form its extreme boundaries, or the length of the visual ray in different parts, by the number of stars contained in the field of his telescope at different times. He then proceeds to offer some thoughts on the origin of the nebulous strata of the heavens; in doing which, he gives some hints concerning the antiquity of them; conjectures which, though abundantly ingenious, are of too fanciful a nature to justify us in detailing them.

206. An objection naturally occurred in the course of Herschel's observations and enquiries concerning the structure of the heavens; that if the different systems were formed by the mutual attractions of the stars, the whole would be in danger of destruction by their falling one upon another.

207. Several circumstances, however, he says, manifestly tend to a general preservation. The indefinite extent of the sidereal heavens, must produce a balance that will effectually secure all the great parts of the whole from approaching

to each other. 'There remains then (says he) only to see how the particular stars belonging to separate clusters are prevented from rushing on to their centres of attraction.' This he supposes may be done by projectile forces; 'the admission of which will prove such a barrier against the seeming destructive power of attraction, as to secure from it all the stars belonging to a cluster, if not for ever, at least for millions of ages. Besides, we ought perhaps to look upon such clusters, and the destruction of a star now and then in some thousands of ages, as the very means by which the whole is preserved and renewed. These clusters may be the laboratories of the universe, wherein the most salutary remedies for the decay of the whole are prepared.'

208. The existence of such projectile forces is rendered probable, from the apparent changes of position of certain stars; and from a comparison of the best modern observations with the most accurate of former times, there appears to have been a real change in the places of some of them. The Bull's Eye, Sirius, and Arcturus, are now found to be half a degree more southerly than the ancients reckoned them; and the bright star in the shoulder of Orion, has, in Ptolemy, almost a whole degree of latitude more southerly than at present. And, as we have already noticed, such remarkable changes have been observed both in the positions and distances of so many of the double stars, that we are constrained to admit that nothing created is stable. Appearances, indeed, indicate that our own system is in motion towards a point of the heavens whose right ascension is about 250° and declination about 50° north. Whether this motion is one of rotation about some distant centre, or of direct motion, must be left to time and accurate observation to determine. The consequence of this motion, however, is, certain apparent motions of several of the fixed stars, entirely unconnected with the phenomena arising either from the earth's figure, or its revolution round the sun. Dr. Maskelyne has given a table containing the proper motions, both in right ascension and declination, of thirty six of the principal fixed stars. We subjoin this table as one of great importance to the practical astronomer.

209. Table of the annual proper motions of thirty-six fixed stars, in right ascension and declination:

Names of the Stars.	Annual Proper Motion.	
	In right ascension.	In declination.
γ Pegasi	0·09	— 0·15 N.
α Aurigæ	+ 0·10	+ 0·07 S.
α Ceti	— 0·12	— 0·08 N.
Aldebaran	+ 0·03	+ 0·12 S.
Capella	+ 0·21	+ 0·44 S.
Rigel	— 0·03	— 0·16 N.
β Erii	+ 0·04	+ 0·10 S.

α Orion	+ 0·01	— 0·13 N.
Sirius	— 0·42	+ 1·04 S.
Castor	— 0·15	+ 0·44 S.
Procyon	— 0·80	+ 0·95 S.
Pollux	— 0·74	0·00
α Hydræ	— 0·09	— 0·14 N.
Regulus	— 0·22	— 0·08 N.
β Leonis	— 0·57	+ 0·07 S.
β Virginis	+ 0·74	+ 0·24 S.
Spicæ Virginis	— 0·02	— 0·19 N.
Arcturus	— 0·26	+ 1·72 S.
1 } α Libræ	— 0·11	— 0·18 N.
2 }	— 0·11	— 0·15 N.

PART II.

OF THE VARIOUS SYSTEMS OF ASTRONOMY.

SECT. I.—OF THE MOST FAMOUS SYSTEMS, BY WHICH THE CELESTIAL PHENOMENA HAVE BEEN ATTEMPTED TO BE EXPLAINED.

210. To explain the motions and appearances of the heavenly bodies, various hypotheses have been formed; and every hypothesis that ever was framed, accounted for some one or other of them; but men being, in the early ages, ignorant of the laws of motion, could not be expected to discover the true system, or explain all the various phenomena of the celestial orbs.

211. In treating of the systems which have been invented in different ages, we do not mean to give an account of all the various absurdities that have been broached by individuals on this subject; but to confine ourselves to those systems which have been of considerable note, and been generally followed for a number of years. We are as ignorant of the opinions of the first astronomers, respecting the system of the universe, as we are of the astronomers themselves. Whatever opinions are handed down to us, must be of much later date than the introduction of astronomy among mankind.

212. If we may hazard a conjecture, however, we are inclined to think, that the first opinions on this subject were much more just, than those that were held afterwards for many years. Pythagoras maintained the motion of the earth, which is now universally believed, but at that time appears to have been the opinion of only a few detached individuals in Greece. As the Greeks borrowed many things from the Egyptians, and Pythagoras had travelled into Egypt

and Phœnicia, it is probable he might receive an account of this hypothesis from thence; but whether he did or not, we have now no means of knowing, neither is it of any importance. Certain it is, however, that this opinion did not prevail in his days, nor for many ages afterwards.

213. In the second century the Pythagorean hypothesis was superseded by a system erected by the famous geographer and astronomer, Claudius Ptolemæus. This system, which commonly goes by the name of the Ptolemaic, he seems not to have originally invented, but adopted as the prevailing one of that age; and he, perhaps, made it somewhat more consistent than it was before. He supposed the earth at rest in the centre of the universe. Round the earth, and the nearest to it of all the heavenly bodies, the moon performed its monthly revolutions. Next to the moon was placed the planet Mercury; then Venus; and above that the Sun, Mars, Jupiter, and Saturn, in their proper orbits; then the sphere of the fixed stars; above these, two spheres of what he called chrySTALLINE heavens; above these was the primum mobile, which, by turning round once in twenty-four hours, by some unaccountable means or other, carried all the rest along with it. This primum mobile was encompassed by the empyrean heaven, which was of a cubic form, and the seat of angels and blessed spirits. Besides the motions of all the heavens round the earth once in twenty-four hours, each planet was supposed to have a particular motion of its own; the moon, for instance, once in a month, performed an additional revolution, the sun in a year, &c. See Plate VII. fig. 4.

214. It is evident, that on this supposition, the complicated motions of the planets already described could never be accounted for. Had they circulated uniformly round the earth, their apparent motion ought always to have been equal and uniform, without appearing either stationary or retrograde in any part of their courses. In consequence of this objection, Ptolemy was obliged to invent a great number of circles, interfering with each other, which he called epicycles and eccentrics. These proved a ready and effectual salvo for all the defects of his system; as whenever a planet was deviating from the course it ought on his plan to have followed, it was then only moving in an epicycle or an eccentric, and would in due time fall into its proper path. As to the natural causes, by which the planets were directed to move in these epicycles and eccentrics, it is no wonder that he found himself much at a loss, and was obliged to have recourse to divine power for an explanation, or, in other words, to own that his system was unintelligible. It, however, continued to be in vogue till the beginning of the sixteenth century, when it was superseded by the Copernican, of which afterwards.

215. The only other systems worth mentioning, besides the true system, are the Tychonic, the semi-Tychonic, and the Cartesian; all of which have gained proselytes, though none of them were ever so universally received as the Ptolemaic and Copernican.

216. The Tychonic system, plate VII. fig. 7,

was invented by Tycho Brahe, who supposed that the earth was at rest, and that the moon and sun revolved about it; the moon in a month, and the sun in a year; and at the same time, that the rest of the planets, Mercury, Venus, Mars, Jupiter, and Saturn, revolved round the sun; the three last also encompassing the earth. Besides these motions, he supposed them all to have a diurnal motion round the earth, as well as all the stars.

217. The semi-Tychonic system supposed the planets to revolve round the sun, while the sun and moon revolve about the earth as their centre of motion; and it supposed the earth to move about its axis from west to east in twenty-four hours. This system differs from the Tychonic only in this, that it supposes a diurnal motion in the earth, but, like the Tychonic, denies an annual one.

218. The Cartesian system, so named from its author, Des Cartes, supposes a variety of vortices or whirlpools, in which the motions of the heavenly bodies are performed, being carried round the sun in a vortex of ethereal matter, in different times, proportioned to their distances; and each planet having also a particular vortex of its own, in which the motions of its satellites are performed. From the laws of motion it will easily appear, that the irregular motions of the planets cannot be accounted for by these vortices; and besides, the supposition of an ethereal matter to perform the operations, is without any foundation, or analogy in nature.

SECT. II.—OF THE COPERNICAN, OR TRUE SYSTEM OF ASTRONOMY.

219. The Ptolemaic system had gained universal credit, when Copernicus began to entertain doubts of its truth, and to try if a more satisfactory method of accounting for the apparent motion of the celestial bodies, might not be obtained. He had recourse to every author upon the subject, but obtained no satisfaction, till he found from Cicero, that Nicetas, the Syracusan, had maintained the motion of the earth; and from Plutarch, that Pythagoras and others of the ancients had been of the same opinion.

220. From these small hints, this great genius deduced a most complete system of astronomy, capable of solving every phenomenon in a satisfactory manner:—a system which has been more and more confirmed by the discoveries and improvements that have been made in astronomy and mathematics, since his time; as well as by the use of telescopes, which have discovered numerous celestial phenomena formerly quite unknown. Like all important discoveries, however, when they run counter to general prejudices, the Copernican system was at first much opposed; and by none more than the celebrated Tycho Brahe, who could never assent to the motion of the earth, and who invented the system described in the last section, with a view to supersede the necessity of it.

221. But while philosophers were divided between the Ptolemaic, the Tychonic, the Cartesian, and Copernican systems, Sir Isaac Newton laid down the laws of nature and motion, and,

comparing all the phenomena in the heavens, discovered the true system of the universe, confirmed the Copernican system of astronomy, and demonstrated its truth by unanswerable arguments, drawn from the most obvious laws of nature. This system, which is founded on a basis not to be shaken, is as follows :

222. The sun, which to us is the fountain of light and heat, is an immense spherical body, which revolves on its own axis in about twenty-five days; and is the centre round which eleven other bodies, called planets, are known to revolve at different distances and in different periods. The planes in which the planets revolve all pass through the centre of the sun, and they are in general inclined to each other in very small angles. They are called primary planets, and some of them are attended by smaller ones, called satellites, which revolve round them in the same manner as they revolve round the sun. See plate III.

223. The sun and the planets are called the solar system. The orbits of the planets are not strictly circular, but elliptical or oval, and the sun is situated in a focus of the ellipse; so that the planets, at one period of their revolution, are nearer to the sun than at another.

224. Besides the periodical revolution round the sun, each of the planets has a uniform rotatory motion round an imaginary line, called the axis, passing through the centre; and, during the whole of any planet's revolution, its axis of rotation preserves the same parallel position. In consequence of this rotation, the different parts of the surfaces of the planets are presented to the sun in succession; but it has not been observed, that the axis round which any planet rotates, is perpendicular to the plane in which it revolves round the sun; therefore, at one period of the revolution, one extremity of the axis and the adjacent parts of the surface will be inclined towards the sun, and the other at the opposite period.

225. There is a class of bodies called comets, which also revolve round the sun, and appear to be governed in their motion by the same laws that regulate the motions of the planets. Their orbits are greatly elongated, and they come towards the sun from all quarters of the heavens, differing in this respect from the planets, which revolve pretty nearly in the sun's plane. They are further distinguished from the other stars, by a luminous stream of light which they emit when they come near the sun.

226. The earth, on which we live, is one of the planets; it revolves round the sun in a year, and performs its rotation on its axis, from west to east, once in a day. The moon is a satellite attending the earth, round which it revolves from west to east in about twenty-seven days eight hours.

227. The planets, in the order of their distance from the sun, are: Mercury, Venus, the Earth, Mars, Vesta, Juno, Ceres, Pallas, Jupiter, Saturn, and Herschel, Uranus, or the Georgium Sidus. Mercury, and Venus, which are nearer the sun than the earth, are called inferior planets; and those which are more distant are called superior planets, as Jupiter, Saturn, and Herschel. These latter, indeed, are also by far the largest. Venus, Juno, Ceres, and Pallas, which are all nearly at

the same distance from the sun, and all lately discovered, are so small that they are generally called asteroids, Jupiter has four satellites; Saturn seven; and Herschel six: Saturn is besides surrounded with a thin, broad, and beautiful ring, perfectly detached from his body. When an inferior planet is between the earth and the sun, its dark side being turned towards the earth, it cannot of course be seen by us, except as a spot apparently passing over the surface of the sun; but it can only be so seen when it passes the sun in one of those points in which its orbit enters into the plane of the earth's orbit. These points are called the nodes of the planet's orbit. For the characteristic marks of the sun and planets, see plate VIII. fig. 8.

228. The fixed stars are at an immense distance; for it has not yet been determined, by the nicest observations, that they have any annual sensible parallax; that is, they appear to the earth, when on different sides of its orbit, to be exactly in the same places, the earth's orbit seen from a fixed star, appearing only as a point. Consequently, the fixed stars all shine with their own native light: for it would be impossible for light, transmitted from the sun, ever to render them visible, as it would be infinitely weak at so immense a distance.

229. The distance of the sun is immensely great, in comparison with that of the moon, although it is almost nothing with respect to that of the fixed stars. For the sun's diurnal parallax, that is, the apparent semidiameter of the earth seen from the sun, is so small, that no instruments could be so exactly made as to find it. Hence, it is inferred, that the sun's magnitude is vastly greater than the earth's. For, supposing the sun's parallax to amount to as much as a minute, then, since the apparent diameter of the sun is half a degree, this would make the sun's diameter fifteen times as big as the earth's; but the sun's parallax has been found not to exceed $8\cdot7''$, which will make the sun's diameter 100 times as great as the earth's. That the sun is of a globular form, is plain from the apparent motion of the spots upon its surface; for while the sun moves uniformly about its axis, the spots in the middle of the disk move very quickly, and near the edges more slowly, agreeably to the motion of a globe about its axis. By observations on these spots, the sun is found to revolve about its axis in twenty-five or twenty-six days.

230. None of the celestial bodies in our planetary system shine with their own native light, except the sun; so that all the planets, both primary and secondary, are opaque bodies, that have no other light but what they receive from the sun, and reflect it back towards the earth and other planets. This is evident from the moon; for only that side of her is observed to shine which is directly opposed to the sun; but the other side, which is from the sun, is quite dark, except so far as it is illuminated by the reflection from the earth; for the more of the illuminated side that is turned towards the earth, the more we see her enlightened, the rest being dark; and the more of her dark side that is turned towards the earth, the more of her appears dark. Thus, at the full, she appears all enlightened, and at her change, all dark.

COPERNICAN SYSTEM.

Comparative Magnitude of the Planets

231. Mercury and Venus exhibit similar phenomena, and show all the phases of the moon according to their various situations. Mars likewise appears gibbous when near the quadratures with the sun. The satellites of Jupiter are eclipsed when they are behind his body, being then immersed in his shadow; they likewise cast their shadows upon the body of Jupiter.

In Saturn, the shadow of the ring upon his body, proves its opacity. And the weakness of the light of those that are far distant from the sun, shows that it is not innate but borrowed.

232. The following tables contain a synopsis of the periods, distances, &c. of the sun and planets, according to the latest and best observations :

SECT. III. ON CENTRAL FORCES.

236. As the doctrine of central forces is of the greatest importance in the science of astronomy, it will be proper to explain here some of the most material propositions relative to that subject.

237. In this doctrine it is supposed, that matter is equally indifferent to motion and rest; or that a body at rest never moves itself, and that a body in motion never changes either the velocity or direction of its motion, but would move uniformly forward in a straight line for ever, unless some external force or resistance should stop or change it.

238. Hence when a body at rest has a tendency to move, or when a body moving in a straight line, has its velocity continually increased or diminished, or when the direction of a motion is continually changed, and thereby a curve line described; it is supposed that these circumstances proceed from the influence of some power that acts incessantly, which power may be measured in the first case by the pressure of the quiescent body against the obstacle that hinders it from moving; or by the change made on the velocity in the second case; or by the flexure of the curve described in the third case; due regard being had to the time in which these effects are produced, and other circumstances, according to the principles of mechanics. Now the power or force of gravity produces effects of each of these kinds, which fall under our observation at the surface of the earth; for the same power that renders bodies heavy while at rest, accelerates their motion when they descend perpendicularly, and bends the path of their motion into a curve line when they are projected in a direction oblique to that of their gravity. But we can judge of the forces or powers that act on the celestial bodies by effects of the last kind only, and hence it is that the doctrine of central force is of so much use in the theory of the planetary motions.

239. The following proposition is the foundation of this doctrine, and is given by Sir I. Newton in his Principia. The areas which revolving bodies describe by radii drawn to an immovable centre of force, lie in the same planes and are proportional to the times in which they are described. Let the time supposed be divided into equal parts, and in the first part let a body be supposed, by its own inert force, to describe a right line, AD, Plate VIII. fig. 5. From what we have promised it will appear, that in the second part of time the body would describe the line DB equal to AD, if nothing acted upon it. But when the body is come to D, suppose a centripetal force attending to the point C acts upon it by a single impulse, such, that it would have carried the body from D to a in the same time. The body E, now acted upon by two powers, one in the direction DB, and another in the direction DC passing through the centre of force, if the parallel line DBE be completed, the body will move in the diagonal DE, and at the end of the time will be found at E, by the principles of mechanics. Join AC, CE; the triangle ADE, DDB, having equal bases, will therefore be equal, and the triangles CDB, CDE, are equal, but they stand on the same base CD, and in between the parallels DC, BE; therefore

the triangles ACD, DCE are equal. By the same method of reasoning, if in the third part of time the body describes any other right line EG, it may be proved that the triangle CDE is equal to CEG; and in a fourth part of time there will be described a triangle CGI equal to CEG, and so on: it is also obvious that the lines AD, DE, EG, GI, &c. lie in the same plane.

240. Thus it appears that in equal times the areas described by radii drawn to the centre of force will be equally increased, and therefore by composition, any sums of the areas are to one another, as the times in which they are described. Let the number of triangles be supposed to be now augmented, and their breadth diminished *ad infinitum*, the lines AD, DE, EG, GI, &c. will now become a curve line lying in the same plane, and the centripetal force which was supposed to act by starts, will now act continually, deflecting the body from the tangent, and thus causing it to move in a curve.

241. We may hence infer, that the velocity of a body attracted towards an immovable centre, in spaces void of resistance, is reciprocally as a perpendicular let fall from that centre on the right line that touches the orbit. For draw CY perpendicular to DE, and suppose the body to describe DE in a given time, hence the velocity of the body will be proportional to DE, and from what has been said, the area of the triangle CED will be given, for it is proportional to the time; but when the area of a triangle remains the same, the base varies inversely as the perpendicular, therefore DE, or the velocity of the body, is inversely as CY the perpendicular; and the same will hold true, whether the body, by successive impulses, moves by a polygon in the way here described; or, by the continual action of the central force, moves in a curve line.

242. The central force of a body moving in the circumference of a circle, is as the versed sine, AM (plate X. fig. 7), of the indefinitely small arc AE; or it is as the square of that arc divided by the diameter AB. For AM is the space through which the body is drawn from the tangent in the given time, whence 2AM is the measure of the intensity of the force. But AE being very small, and therefore nearly equal to

its chord, we have $AM = \frac{AE^2}{AB}$. If therefore

two bodies revolve uniformly in different circles, their central forces are directly as the squares of their velocities, and inversely as the diameters, or as the radii of the circles. For the velocities are as the space uniformly described in the same

time. Hence, $F : f :: \frac{V^2}{D} : \frac{v^2}{d}$. Hence, if the diameters are inversely as the squares of the velocities, the forces will be as the fourth power of the velocities.

244. The central forces are to each other as the diameters divided by the squares of the periodic times. For if C be the circumference described in the time t , with the velocity v , then

$$C = tv, \text{ or } v = \frac{C}{t} \quad \text{Hence, } F : f :: \frac{V^2}{D} \cdot \frac{t^2}{d^2}$$

$:: \frac{C^2}{Dt^2} : \frac{c^2}{dt^2} :: \frac{D}{T^2} : \frac{d}{t^2}$; for the diameter varies as the circumference.

Fig 1.

Fig 2.

Fig 3.

Fig 4.

Fig 6.

Fig 5.

Fig 7.

245. If two bodies, revolving in different circles, be acted upon by the same central force, their periodic times are as the square roots of the diameters, or of the radii of those circles. For when $F = f$, the expression $F : f :: \frac{D}{T^2} : \frac{d}{t^2}$, gives $\frac{D}{T^2} = \frac{d}{t^2}$, whence $T : t :: \sqrt{D} : \sqrt{d}$.

246. If the velocities be inversely as the distances from the centre, the forces will be inversely as the cubes of the same distances, or directly as the cubes of the velocities. For $F : f :: \frac{V^2}{D} : \frac{v^2}{d}$; whence, if D vary as V , inversely,

$F : f :: V^3 : v^3$; or $F : f :: d^3 : D^3$.

247. If the velocities be inversely as the square roots of the radii, the squares of the times will be as the cubes of the radii. For, as has been shewn above, $F : f :: \frac{V^2}{R} : \frac{v^2}{r}$; and $F : f ::$

$\frac{R}{T^2} : \frac{r}{t^2}$; whence $\frac{V^2}{R} : \frac{v^2}{r} : \frac{R}{T^2} : \frac{r}{t^2}$. And if $V^2 :$

$v^2 :: r : R$, this proportion becomes $\frac{r}{R} : \frac{R}{r} ::$

$\frac{R}{T^2} : \frac{r}{t^2}$. When $\frac{r^2}{Rt^2} = \frac{R^2}{rT^2}$, or, $\frac{r^3}{t^2} = \frac{R^3}{T^2}$, or

$T^2 : t^2 :: R^3 : r^3$. Hence, also, if the forces be inversely as the squares of the radii, the squares of the periodic times will be as the

cubes of the distances. For $F : f :: \frac{R}{T^2} : \frac{r}{t^2}$ hence, $r^2 : R^2 :: \frac{R}{T^2} : \frac{r}{t^2}$, or $T^2 : t^2 :: R^3 : r^2$

248. We shall now apply the doctrine of central forces, to the circumstances of a planet revolving in an ellipsis, by a force directed towards the focus.

249. Let $ABHL$ (plate VI. fig. 2) represent the ellipsis, S and A the foci, and let P be the place of the planet, and PT a tangent at P , and let Pp be an indefinitely small arc described by the planet. Join PS , pS , and draw pF parallel to SP , meeting PT in F . Then pF is the central force in the arc pP . Let a = the parameter of the transverse AH ; or let $aAC = 2BC^2$. From p draw pI parallel to PT , meeting PK in I , and SP in i . Then the triangles PiI , PCE being similar, and Pi equal and parallel to pF . Pi or $pF : PI :: PE$, or (by conics) $AC : PC$. When $a \cdot pP : a \cdot PI :: AC : PC$. And similarly $a \cdot PI :: PI \cdot IK :: a : KI$; and by the property of the ellipse $IP \cdot IK : IP^2 :: PC^2 : CN^2$. From p draw pM perpendicular to SP , then in the similar right angled triangles PiM PED , we have ip , or Ip (for they differ by quantities indefinitely small) $pM :: PE : PD$. But by conics $PE : PD :: CN : CB$, whence $Ip : pM :: CN : CB$, and consequently $IP^2 : pM^2 :: CN^2 : CB^2$. Hence, by comparing these proportions, we have $pF \cdot a \cdot IP \cdot IP \cdot KI : IP^2 :: IP \cdot a \cdot IP \cdot KI : IP^2 \cdot pM^2 :: CA \cdot a \cdot PC^2 \cdot CN^2 : PC \cdot KI \cdot CN^2 \cdot CB^2$; or by reduction $a \cdot pF : pM^2 :: a \cdot AC \cdot PC : KI \cdot CB^2$; or, $a \cdot pF : pM^2 :: 2CB^2 \cdot PC : CB^2 \cdot KI :: PC : KI$. But P and I being indefinitely near, KI

$= KP = 2PC$; therefore $a \cdot pF = pM^2$. Now the time in Pp is represented by the area of the triangle SPp or by $\frac{SP \cdot pM}{2}$, whence $T^2 = \frac{SP^2 \cdot pM^2}{4}$, and consequently $pM^2 = \frac{4T^2}{SP^2}$

whence pF (the force) $= \frac{4T^2}{a \cdot SP^3}$, or (as the increments of time are uniform), the force is inversely as the square of the distance from the focus.

250. We may hence infer, that if several planets revolve in different ellipses about a common focus, that the areas of the sectors described in the same time are as the square roots of the parameter of the transverse axes. For by conics $a \cdot pF = pM^2$; but pF varies as $\frac{1}{SP^2}$, hence $a = \frac{pM \cdot SP^2}{pM^2}$, or $\sqrt{a} = PM \cdot SP$. But PM , SP is proportionate to the area of elementary sector SPp , which therefore varies as $t\sqrt{a}$.

251. We may farther infer, that the velocities in the different ellipses, are as the square root of the parameter of the transverse, divided by the perpendicular from the focus on the tangents, passing through the places of the planets. For the velocity, in an indefinitely small space of time, is as the arc pP ; and from the similar triangles SPT , pMP , an hour $ST : SP :: PM : pP$.

Whence $pP = \frac{SP \cdot pM}{ST} = \frac{\sqrt{a}}{ST}$

252. It is farther apparent from what has been done, that the areas of the different ellipses are to each other as the product of the times by the square roots of the parameters of the transverse axes. For the area, Q , is as the product of the sector SPp by the time, t , and the sector varies as \sqrt{a} ; therefore Q varies as $t\sqrt{a}$.

253. Again, the squares of the periodic times are proportional to the cubes of the transverse axes. For let b be the less, d the greater axis, and a the parameter; then by conics $a \cdot d = b^2$, or $a \cdot d^3 = b^2 \cdot d^2$. But the whole areas are as the product of the axes; and also, as has been just shown, as $t\sqrt{a}$. Hence $b^2 \cdot d^2$, or $d^3 \cdot a = t^2 \cdot a$, or d^3 varies as t^2 .

SECT. IV. OF THE ORBITS AND MOTIONS OF THE PRIMARY PLANETS.

254. For the theorems in the preceding section on the subject of central forces we are indebted to the sagacity of Newton. They had before his time, however, been found by Kepler to be true in the case of the known planets of the solar system. Kepler showed that these laws *did* obtain in the system; Newton shewed that they *must* obtain.—The three fundamental laws of planetary motion which Kepler discovered, and of which the demonstrations given above, are these.

255. 1. The primary planets and comets describe round the sun, and the secondary planets describe round their respective primary planets, areas proportioned to the times.

256. 2. The orbits described round the sun, and round the primary planets, are ellipses, having the sun of the primary planet in the focus.

257. 3. The squares of the periodic times of planets revolving round common centres, are proportional to the cubes of their mean distances.

258. These laws are universal; they are obeyed by all the planets of our system, which revolve nearly in the same plane, and they are found to obtain also in the comets which move round the sun in all directions.

259. In addition to what has been said, the following popular illustration may be given of the peculiarities of the motion of a planet in the different planets of its orbit. Let AB and EF be the axis of an ellipse, of which D is the centre, and C the focus. See plate VIII. fig. 4. Suppose that P is the place of a planet moving in the curve $AFBE$, (supply P in the fig.) and that PG is drawn touching the curve at P . Join CP , CE , and draw CG perpendicular to PG . The place of the sun will be at C the focus, and the planet will move in the curve; so that the line CP shall pass over equal areas in equal times. Since the velocity of the planet is inversely as the perpendicular upon the tangent, and the lines CB , CA , are perpendicular to tangents at the points B and A , the velocity at A , as CA to CB , and the velocity at B is to the velocity at P as CG to CB . Thus at B , which is called the perihelion, the velocity will be the greatest, and at A , the aphelion, it will be the least; and at any other point, P , it will be between these two extremes. The line CE is equal to BD , which is a mean between BC and CA ; and when the planet is at E , it is said to be at its mean distance. The force, that, acting upon the planet at P , bends it from the tangent, is to the force that acts upon it at E , any other point, as the square of CE to the square of CP .

260. We have hitherto supposed the sun to remain absolutely at rest, and that the planet was urged towards it, as to an immovable point; but the tendency of the planets towards the sun, arises from a law, that not only connects the planets with the sun, but with each individual particle of matter in the solar system; a particular cause of this law or fact, is the gravity of bodies at the surface of our earth, and the general law that includes all particular cases, has been termed gravitation. Hence it follows, that not only the planets gravitate towards the sun, but the sun gravitates towards the planets; so that, in strict truth, both the sun and each planet revolve round a point, which is their common centre of gravity, and which is as much nearer to the sun than to the planet, as the sun contains more matter than the planet.

261. The truth of this general law is only to be proved by a careful examination of particular cases: and, supposing it to be true, the effects it ought to produce in the planetary motions round the sun, are in perfect coincidence with the best observations.

262. If all matter gravitates to, or is attracted by, all other matter, it is evident that the planets must also gravitate towards each other; and thus in some measure the uniformity of their motions round the sun will be affected. Now, by the most accurate observations, this is really

found to be the case; and the effects produced are precisely what they ought to be, supposing that the same law, which regulates the tendency of the planets towards the sun, also regulates their tendency to one another.

263. If the planets were acted on by a power directed to the centre of the sun only, varying according to the general law of gravity, and that centre were quiescent, their motions about it would be perfectly regular; but since they are acted on by a power directed to every body in the system, in order to judge of the effects of these actions, Newton first supposes two bodies revolving about their common centre of gravity, and gravitating towards each other, and since the direction of this mutual gravitation passes always through that centre, and their distances from it vary always in the same proportion as their distances from each other, they must describe similar figures about that point and about each other, and describe equal areas in equal times, about that centre, and about each other; so that there will be no irregularities in the motion of two bodies about each other, because of their mutual attractions, whatever the law of their gravity is supposed to be; only they will revolve in less time about their centre of gravity, than the one would have done about the other quiescent, because the orbit described about the other centre of gravity is less than that which is described by any one of them about the other quiescent; their distance in both cases being the same, and the orbits similar.

264. If three or more bodies mutually attract each other, the gravitation of any one of them, arising from the attractions of the rest, may be determined by the rule for composition of motion; and if the law of gravity be such as obtains in the solar system, its gravitations will not be always directed to the centre of gravity of the other bodies, or indeed to any fixed point, but sometimes to one side of that centre and sometimes to the other, and therefore equal areas will not be described in equal times about any point in the system; and some irregularities will therefore arise in the motions of the bodies.

265. But if one of these bodies should be vastly greater than the others, so that the actions of the other bodies may be neglected, when compared with its action; and the centre of gravity of the system be always found near it, the irregularities of such a system will be very small, the areas described in equal times about the centre of the great body will be nearly equal, and the orbits described will be nearly elliptic, having that centre in their focus.

266. We have seen that the determination of the circumstances relative to two bodies in motion, is a matter of great simplicity; but when the number of bodies is increased even by one, the general estimation of their effects on each other's motions is a problem that has hitherto baffled the skill of the most eminent philosophers. It happens very fortunately that, in the only case in which it is of much importance to us, it admits of an approximate solution, from the sun being so much greater than all the other planets; for in the case of the

moon, the sun, and the earth, which we may take for the sake of illustration, the sun disturbs the motions of the moon as seen from the earth, only by the difference of its attractions on the moon and the earth, which difference, when compared with the former by which the moon is attracted towards the earth, is always very small.

267. The action of Jupiter on Saturn, when greatest (that is, when their distance is least), is found by calculation to be $\frac{1}{31}$ of the action of the sun upon Saturn. This produces an effect which is decidedly perceptible.

268. The whole action of Jupiter disturbs the motion of Saturn in their conjunction, because Jupiter then acts upon Saturn and upon the sun in opposite directions. But because Saturn then acts upon Jupiter and upon the sun in the same direction, if it acted also with the same force on both, it would have no effect on the motion of Jupiter about the sun; and it is by the excess of its action on Jupiter, above its action on the sun, that it disturbs the motion of Jupiter. This excess is found to be one 1913th part of the action of the sun on Jupiter; and therefore is much less than the force with which Jupiter disturbs the motion of Saturn.

269. The actions of the other planets on each other are incomparably less than these, and the irregularities proceeding from those actions are always less in any planet, as it is nearer the sun; but the orbit of the earth is a little more irregular than that of its neighbouring planets, from the great comparative size of its moon, round the common centre of gravity of which, and the earth, both the earth and the moon make a monthly revolution.

SECT. V.—OF THE ORBITS AND MOTIONS OF THE SECONDARY PLANETS.

270. The same general principle of gravitation which contains the primary planets in their orbits, extends also to the motions of the secondary planets, both in regard to their motion round the sun along with their primaries, and to their motions round their primaries as a centre; which furnishes us with an additional proof of this general law, that all matter gravitates to all other matter with a force reciprocally proportional to the square of the distance.

271. That each secondary planet is kept in its orbit by a power directed towards its primary, &c. is proved from the phenomena of the satellites of Jupiter and Saturn; because they move in circles, as far as we can observe, about their respective primaries with an equal course, the primary being the centre of each orbit: and by comparing the times in which the different satellites of the same primary perform their periods, they are found to observe the same relation to the distances from their primary, as the primary planets observe in respect of their mean distances from the sun. The same thing holds good also with respect to the earth and moon; for she is found to move round the earth in an ellipsis after the same manner as the primary planets do about the sun, excepting only some small irregularities in her motions, the cause of which will be particularly explained in what follows; and it will appear that they

are no objections against the earth's acting on the moon in the same manner as the sun acts on the primary planets; that is, as Jupiter and Saturn act upon their satellites.

272. The power of Jupiter and Saturn may be measured to a very considerable distance, by the number of satellites which move round them; for the distance of the outermost satellite of each of them exceeds several times that of the innermost. That the force which retains the moon in her orbit, bears precisely that relation which accords with its distance to the known force of gravity on the surface of the earth, may be shown by the following very simple process.

273. Let A in plate VII. fig. 5, represent the earth, B the moon, BCD the moon's orbit; which differs little from a circle of which A is the centre. If the moon in B were left to itself to move with the velocity it has in the point B, it would leave the orbit and proceed straight forward in the line BE which touches the orbit in B. Suppose the moon would upon this condition move from B to E in the space of one minute of time: by the action of the earth upon the moon, whereby it is retained in its orbit, the moon will really be found at the end of this minute in the point F, from whence a straight line drawn to A will make the space BFA in the circle equal to the triangular space BEA; so that the moon, in the time wherein it would have moved from B to E, if left to itself, has been impelled towards the earth from E to F. And when the time of the moon's passing from B to F is small, as here it is only one minute, the distance between E and F scarcely differs from the space through which the moon would descend in the same time, if it were to fall directly down from B towards A, without any other motion. AB, the distance of the moon from the earth, is about sixty of the semi-diameters of the latter; and the moon completes her revolution round the earth in about twenty-seven days, seven hours and forty-three minutes: therefore the space EF will here be found by computation to be about $16\frac{1}{2}$ feet. Consequently, if the power by which the moon is retained in its orbit, be greater, near the surface of the earth, than at the distance of the moon, in the duplicate proportion of that distance, the number of feet a body would descend near the surface of the earth, by the action of this power upon it, in one minute, would be equal to the number $16\frac{1}{2}$ multiplied twice into the number sixty, that is, to 58,050.

274. Now bodies falling near the surface of the earth have been found, by exact experiments, to descend $16\frac{1}{2}$ feet in one second; and the spaces described by falling bodies being as the squares of the times of their fall, the number of feet a body would describe in its fall near the surface of the earth in one minute of time, would be equal to $16\frac{1}{2}$ multiplied by 60^2 ; the same as the power which acts upon the moon would cause.

275. We may hence conclude, that the power which retains the moon in her orbit is the same as that which causes bodies near the surface of the earth to gravitate; for, since the power by which the earth acts on the moon will cause

bodies near the surface of it to descend with precisely the velocity they are found to do, it is certain that no other power can act upon them besides; because, if it did, they must of necessity descend more swiftly. It is therefore evident, that the power in the earth which we call gravity, extends up to the moon, and decreases as the square in the same proportion as the square of the distance from the centre of the earth increases. If to the motion of the satellite whereby it would be carried round its primary at rest, we superadd the same motion, both in regard to velocity and direction, as the primary itself has, it will describe about the primary the same orbit with as great regularity as if the primary had been indeed at rest. This proceeds from the law of motion, which makes a body near the surface of the earth descend perpendicularly, though the earth be in a swift motion, of which if the falling body did not partake, its descent would be oblique.

276. From this we learn, that, if the satellite moved about its primary with perfect regularity, besides its motion about the primary, it would have the same progressive velocity with which the primary is carried about the sun, in a direction parallel to that impulse of its primary; and, on the contrary, the want of either of these, in particular of the impulse towards the sun, will occasion great inequalities in the motion of the secondary planet. The inequalities which would arise from the absence of this impulse towards the sun are so great, that by the regularity which appears in the motion of the secondary planets, it is proved, that the sun communicates to them the same velocity by its action as it gives to their primary at the same distance.

277. The sun therefore acts upon the secondary planets with the same force as upon the primaries at the same distance: but the action of the sun upon bodies is reciprocally in the duplicate proportion of the distance; therefore the secondary planets being sometimes nearer to the sun than to the primary, and sometimes more remote, they are not always acted upon in the same degree with their primary, but when nearer to the sun are attracted more, and when farther off are attracted less. Hence arise various inequalities in the motions of the secondary planets. Some of these inequalities, however, would take place, though the moon, if undisturbed by the sun, had moved in a circle concentric to the earth, and in the plane of the earth's motion; others depend on the elliptical figure and oblique situation of the moon's orbit. One of the former is, that the moon does not describe equal spaces in equal times, but is continually accelerated as she passes from the quarter to the new or full, and is retarded again by the like degrees in returning from the new and full to the next quarter; but here we consider not so much the absolute as the apparent motions of the moon with respect to us.

278. These two may be distinguished in the following manner.—Let S, in plate X, fig. 6. represent the sun, A the earth moving in its orbit, BC, DEFG the moon's orbit, and H the place of the moon in her orbit. Suppose the earth to have moved from A to I. Because

it has been shown that the moon partakes of all the progressive motions of the earth, and likewise that the sun attracts both the earth and moon equally when they are at the same distance from it, or that the mean action of the sun upon the moon is equal to its action upon the earth; we must therefore consider the earth as carrying about with it the moon's orbit; so that, when the earth is removed from A to I, the moon's orbit shall likewise be removed from its former situation into that denoted by K L M N. But now the earth being in I, if the moon were found in O, so that O I should be parallel to H A, though the moon would really have moved from H to O, yet it would not have appeared to a spectator upon the earth to have moved at all, because the earth has moved as much; so that the moon would still appear in the same place with respect to the fixed stars. But if the moon be observed in P, it will then appear to have moved, its apparent motion being measured by the angle O I P. And if the angle P I S be less than the angle H A S, the moon will have approached nearer its conjunction with the sun. Now, to explain particularly the inequality of the moon's motion already mentioned, let S, plate VIII. fig. 9, represent the sun, A the earth, B C D E the moon's orbit, C the place of the moon when in the latter quarter. Here it will be nearly at the same distance from the sun as the earth is. In this case, therefore, they will be both equally attracted, the earth in the direction A S, and the moon in that of C S. Whence, as the earth, in moving round the sun, is continually descending towards it, so the moon in this situation must in any equal portion of time descend as much; and, therefore, the position of the line A C in respect of A S, and the change which the moon's motion produces in the angle C A S, will not be altered by the sun: but as soon as the moon is advanced from the quarter toward the new or conjunction, suppose to G, the action of the sun upon it will have a different effect. Were the sun's action upon the moon here to be applied in the direction G H parallel to A S, if its action on the moon were equal to its action on the earth, no change would be wrought by the sun on the apparent motion of the moon round the earth. But the moon receiving a greater impulse in G than the earth receives in A, were the sun to act in the direction G H, yet it would accelerate the description of the space D A G, and cause the angle G A D to decrease faster than it otherwise would. The sun's action will have this effect, upon account of the obliquity of its direction to that in which the earth attracts the moon. For the moon by this means is drawn by two forces oblique to one another: one drawing from G towards A, the other from G towards H; therefore the moon must necessarily be impelled towards D.

279. Again, because the sun does not act in the direction G H parallel to S A, but in the direction G S oblique to it, the sun's action on the moon will, by reason of this obliquity, farther contribute to the moon's acceleration. Suppose the earth, in any short space of time, would have moved from A to I, if not attracted by the sun, the point I being in the straight line C E, which touches the earth's orbit in A. Suppose the moon

in the same time would have moved in her orbit from G to K, and besides have partaken of the progressive motion of the earth. Then, if KL be drawn parallel to AI, (the line KL must be supplied in the figure) and taken equal to it, the moon, if not attracted to the sun, would be found in L. But the earth, by the sun's action, is removed from I. Suppose it were moved down to M in the line IMN parallel to SA, and if the moon were attracted but as much, and in the same direction as the earth is here supposed to be attracted, so as to have descended during the same time in the line LO parallel also to AS, down as far as P, till LP were equal to IM, let PM be joined, the angle PMN will be equal to LIN; that is, the moon will appear advanced as much farther forward as if neither it nor the earth had been subject to the sun's action. But this is on the supposition that the actions of the sun upon the earth and moon are equal; whereas the moon being acted upon more than the earth, did the sun's action draw the moon in the line LO parallel to AS, it would draw it down so far as to make LP greater than IM, whereby the angle PMN will be rendered less than LIN. But, as the sun draws the earth in a direction oblique to IN, the earth will be found in its orbit, somewhat short of the point M. However, the moon is attracted by the sun, still more out of the line LO, than the earth is out of the line IN; therefore, this obliquity of the sun's action will yet farther diminish the angle under PMN. Thus the moon, at the point G, receives an impulse from the sun, whereby her motion is accelerated; and the sun producing this effect in every place, between the quarter and the conjunction, the moon will move from the quarter, with a motion continually more and more accelerated; and therefore, by acquiring, from time to time, an additional degree of velocity in its orbit, the spaces which are described in equal times by the line drawn from the earth to the moon, will not be everywhere equal, but those towards the conjunction will be greater than those towards the quarter. But, in the moon's passage, from the conjunction D to the next quarter, the sun's action will again retard the moon, till, at the next quarter at E, it be restored to the first velocity which it had in C.

280. When the moon moves from E to the full, or opposition to the sun in B, it is again accelerated; the deficiency of the sun's action on the moon from what it has upon the earth, producing here the same effect as before the excess of its action. Let us now consider the moon in Q, as moving from E towards B. Here, if she were attracted by the sun in a direction parallel to AS, yet being acted on less than the earth, as the latter descends towards the sun, the moon will, in some measure, be left behind. Therefore, RF being drawn parallel to SB, a spectator would see the moon move as if attracted from the point Q, in the direction RF, with a degree of force equal to that whereby the sun's action on the moon falls short of its action on the earth. But the obliquity of the sun's action has here also an effect. In the time the earth would have moved from A to I, without the influence of the sun, let the moon have moved in its orbit from Q to R. Drawing,

therefore, RT parallel to AI, the moon, by the motion of its orbit, if not attracted by the sun, must be found in T; and therefore, if attracted in a direction parallel to SA, would be in the line TV parallel to AS; suppose in W. But the moon in Q being farther off the sun than the earth, it will be less attracted; that is, TW will be less than IM; and if the line NM be prolonged towards X, the angle XMW will be less than XIT.

281. Thus, by the sun's action, the moon's passage from the quarter to the full would be accelerated, if the sun were to act on the earth and moon in a direction parallel to AS; and the obliquity of the sun's action will still increase this acceleration: for the action of the sun on the moon is oblique to the line SA, the whole time of the moon's passage from Q to T, and will carry her out of the line TV towards the earth. Here we suppose the time of the moon's passage from Q to T so short, that it shall not pass beyond the line SA. The earth will also come a little short of the line IN, as was already mentioned; and from these causes the angle XMW will be still farther lessened. The moon, in passing from the opposition B to the next quarter, will be retarded again in the same manner as it was accelerated before its appulse to the opposition; and thus the moon, by the sun's action upon it, is twice accelerated, and twice restored to its first velocity every circuit it makes round the earth; and this inequality of the moon's motion about the earth is called by astronomers its variation.

283. The orbit of the moon is dilated when nearer the sun, and contracted when she is more remote: for it has been proved by Newton, that the action of the sun, by which it diminishes the earth's power over the moon in the conjunction or opposition, is about twice as great as the addition to the earth's action by the sun in the quarters; so that, upon the whole, the power of the earth on the moon is diminished by the sun; and therefore is most diminished when that action is strongest. But as the earth, by its approach to the sun, has its influence lessened, the moon, being less attracted, will gradually recede from the earth; and as the earth, in its recess from the sun, recovers by degrees its former power, the orbit of the moon must again contract.

284. Two consequences follow from hence, viz. that the moon will be more remote from the earth, when the latter is nearest the sun, and will take up a longer time in performing its revolution through the dilated orbit, than through the more contracted. These irregularities would be produced, if the moon, without being acted upon unequally by the sun, should describe a perfect circle about the earth, and in the plane of its motion: but, though neither of these circumstances take place, yet the above-mentioned inequalities occur only with some little variation with regard to the degree of them; but some others are observed to take place from the moon's motion being performed in the manner already described. For, as the moon describes an ellipsis, having the earth in one of its foci, this curve will be subjected to various changes, neither preserving constantly the same figure nor position; and,

because the plane of this ellipsis is not the same with that of the earth's orbit, it follows, that the former will continually change; so that neither the inclination of the two planes towards each other, nor the line in which they intersect, will remain for any length of time unaltered.

285. The various forces by which the motion of the moon is disturbed, and the changes which take place in its orbit, may be investigated in the following manner. See plate IX. fig. 13. Let C A B D be the moon's orbit, T the earth, S the sun, P the moon; make SK = ST; and let SK : S L :: S P² : S K². Then if SK or ST represent the sun's force at T, SL will represent his force at P. Draw L M parallel to PT; divide the force LS into the two forces LM acting parallel to PT, and MS acting parallel to TS. But the force LM, and the part TM disturb the moon's motion.— The force LM in its mean quantity is equal to PT, and by so much the force of the earth is increased. Also TM in its mean quantity is equal to 3PK, acting in a direction PN parallel and equal to T S; and the force M T draws the moon out of her orbit. Let P p be the periodical times of the earth and moon; then the sun's centripetal force at T (ST) : the earth's centripetal force at P :: $\frac{ST}{PP} : \frac{PT}{pp}$; therefore the earth's centripetal force at P = $\frac{PT \times PP}{pp}$. And this is to the additional force PT :: $\frac{PT \times PP}{pp} : PT :: PP : pp$.

That is, the force by which the moon is retained in her orbit : is to the increase of centripetal force by the sun's action : : PP : pp :: 178·725 : 1.— Therefore the increase of the moon's centripetal force is $\frac{1}{178·725}$ of that force.

286. Also force PT : force 3PK or PL :: PT : 3 P K. Therefore, ex æquo, the force by which the moon is retained in her orbit : disturbing force PL or TM :: PT × 178·725 : 3 P K. Therefore the disturbing force TM = $\frac{3PK}{PT \times 178·725} \times$ earth's centripetal force on the moon = 3a the sine of the moon's distance from the quadratures × earth's centripetal force, divided by 178·725 × radius.

Let C, c, be the centripetal forces of the sun and earth, s = sine of the moon's distance from the quadrature, radius = r. Then the additional force (PT) = $\frac{c}{178·725}$. And the disturbing force (TM) = $\frac{3sc}{178·725r}$.

Produce TP, and make PR = PL, or TM, and draw RQ perpendicular to TQ. Then QR is the force that accelerates the moon, and PQ is the diminution of its centripetal force.

For the force PR is divided into two forces, P Q, and Q R, of which P Q, acting towards Q, diminishes the moon's centripetal force; and QR being parallel to the tangent at P, accelerates the moon at P.

287. There are therefore four points in the moon's orbit, each 35° 16' from the quadratures, where the moon's disturbing force makes no alteration in the earth's central force.

For the triangles P K T and P Q R are similar, whence PK : PT :: PQ (PT) : PR (3PK); therefore 3 P K² = P T², or 3ss = rr, whence s = $\sqrt{\frac{rr}{3}}$ = S. 35° 16'. And when PQ = PT, the diminution of the force is equal to the addition, which makes no alteration.

The mean force PT is = $\frac{1}{643410}$ of the force of gravity of the earth.

For the force of gravity is 3600 times greater than the force at P.

The whole increase of the centripetal force at P is $\frac{c}{171·725} \times \left(1 - \frac{3ss}{rr}\right)$

For rad (r) : s :: PT $\left(\frac{c}{178·725}\right)$: PK = $\frac{cs}{178·725r}$. And PR = 3PK = $\frac{3cs}{178·725r}$ And

rad (r) : PR $\left(\frac{3cs}{178·725r}\right)$:: S.R (r) : PQ = $\frac{3css}{178·725rr}$. And PT — PQ = whole additional

force = $\frac{1 - \frac{3ss}{rr}}{178·725} c$.

If A = sine of twice the moon's distance from the quadratures; then the force QR, accelerating or retarding the moon's motion in its orbit, is $\frac{3c}{178·725} \times \frac{A}{2r}$.

Let z = S.QPR or KPT = cos. PTK; then rad (r) : RP $\left(\frac{3cs}{178·725r}\right)$:: S.QPR (z) : QR =

$\frac{3c}{178·725rr} \times sz =$ (by trigonometry) $\frac{3c}{178·725} \times \frac{A}{2r}$.

288. Hence the moon is accelerated in the quadrants C A, D B; and retarded in the quadrants A D, B C; and the force which accelerates or retards the moon's motion, is greatest in the octants.

For it is greatest when A is greatest, that is, when 2 C P is ninety degrees, or C P = 45°.

The disturbing force TM, in the syziges A and B, is 2 P T. And therefore the earth's force upon the moon in the syziges, is twice as much diminished, as it is increased in the quadratures.

The moon's orbit is more flat in the syziges, and more curve in the quadratures; and therefore she goes farther from the earth in the quadratures.

For the orbit will be more curve where the central force is greater, that is in the quadratures.

289. The motion of the moon's nodes, supposing her orbit to be nearly circular, may be thus found:

In fig. 7, plate XIII, let A g B Q be the moon's orbit, T the earth, P the moon, S A B the line of the apsides, Q, q the quadratures, m N n the line of the nodes. P K, P H, A Z perpendiculars upon T Q and N n. The force by which the moon is drawn out of her orbit has been found to be

Fig. 13.

$\frac{3s}{178725r} c = \frac{s}{59575r} c$. Let PM be the arch which the moon describes in any small time; and ML a small line, which the moon describes in the same time by the force $\frac{s}{59575r} c$, as this

force is directed to the sun, the line ML will be parallel to TA. As ML is the distance that the moon is drawn from the arch PM, by the said accelerative force; 2ML will be the uniform motion it has acquired in that time, by the said force. Let MP be continued back to *m*, in the moon's orbit, to cut the line of the nodes TN in *m*. Now since ML is parallel to the ecliptic; a plane drawn through ML and MP*m*, will cut the ecliptic in a line *ml*, which will be parallel to ML; therefore draw LPl to cut *ml* in *l*, and the triangles PML and P*ml* are similar, and therefore $ml = \frac{mP \times ML}{MP}$; but since MP is given,

and ML is as the force 3PK, therefore *ml* is as $mP \times PK$. Now when the moon was at P, the line of the nodes was at T*m*, where the plane of the moon's orbit TMP cuts the ecliptic. But, when the moon comes to L (instead of M), the plane of her orbit will then be in the plane TLP; and the line of the nodes at T*l*, where the plane TLP*l* cuts the ecliptic. Therefore the angular motion of the nodes generated in that time will be = angle *mTl*. But the angle *mTl*

is as $\frac{ml}{Tm} \times \text{sine of } Tml \text{ or } ATN$; that is, as $\frac{mP \times PK}{mT} \times AZ$; that is, because by similar triangles $\left(\frac{mP}{mT} = \frac{PH}{PT}\right)$ as $\frac{PH \times PK}{PT} \times AZ$, that is, (because PT is given) as PH \times PK \times AZ.

The line ML is to the versed sine of the arch PM, as the forces that produce them; that is, as $\frac{s}{59575r} c$ to *c*, or as *s* to 59575*r*. That is

$$ML : \frac{PM^2}{2MT} :: s : 59575r; \text{ therefore } ML = \frac{PM^2}{2MT}$$

$\frac{s}{59575r}$. When P falls upon A, or the moon is in the syzygy; then *s* = *r*, and the angle PML is a right angle: therefore in the triangle PML, $PM : ML \left(\frac{PM^2}{2MT \times 59575}\right) :: \text{radius} : S.LPM$ or $mPl = \frac{PM}{2MT \times 59575}$. And if N be at Q,

or the nodes in the quadratures, and P at A; then PM and PL being parallel to the ecliptic, *m* and *l* will be at an infinite distance, and then the angle *mTl* will be equal to *mPl*, whose sine is

$$\frac{PM}{2MT \times 59575}$$

And the angle *mTl* answering to $\frac{PM}{2MT}$ is the motion of the node, whose sine is $\frac{PM}{MT \times 59575}$. Suppose PM to be described in an hour, then PM or the mean horary motion is $32' 56''\frac{1}{2}$, whose sine, as it differs insensibly from the arch, we shall have the arch = $\frac{32' 56''\frac{1}{2}}{59575}$ (putting PM = 1) = $33' 18''$, where all the

angles PTK, PTN, and STN are right angles. And in other cases, the horary motion of the node will be to $33' 18''$, as the product of the sines of the three angles PTK, PTN, and STN, to the radius cube; and the nodes are regressive when all the sines are positive. But if any sine changes to be negative, the nodes will be progressive.

290. Hence the nodes are progressive, when the moon is between either quadrature, and the node nearest that quadrature; otherwise they are regressive. And by the excess of the regress above the progress, they are in the whole moved forward.

For in the arches QAn and qBN, PK and PII are both affirmative or both negative. And in the arches NQ, nq, only one is negative, the other being affirmative.

If it were not for the sun's perturbing force, the moon would always describe the same ellipsis, and the transverse axis and eccentricity of the orbit would remain unaltered. But since the perturbing force of the sun always acts upon her more or less, and causes all the irregularities of her motion; it is evident that all these effects will be the greater as that force is the greater. But when the transverse axis, or line of the apsides, is in the syziges, then the perturbate force TM or 3PK, fig. 13, plate IX., is the greatest possible, by which the moon is removed farther from the earth, and consequently the transverse axis is lengthened, and the eccentricity becomes greater. And the contrary happens when the transverse is in the quadratures; for by its being in the quadratures, the force LM is greater; and the whole centripetal force towards T being greater, the body will be drawn nearer the earth, and describe a less orbit, or one less eccentric than before. Therefore when the apsides are in the quadratures, the eccentricity is less; and when they are in the syziges, it is greater. But how much it is greater or less depends upon the mean eccentricity; and that depends upon observation.

292. Hence the eccentricity continually increases, as the apsides move from the quadratures to the syziges; and decreases from the syziges to the quadratures. And the eccentricity of the orbit continually increases, as the moon passes from the quadratures to the syziges; and decreases, in passing from the syziges to the quadratures. For the perturbing force increases from the quadratures to the syziges, and decreases from the syziges to the quadratures.

SECT. VI.—OF THE NATURE AND MOTIONS OF COMETS.

293. It is certain that comets are not meteors in our air, because they rise and set in the same manner as the moon and stars. It is long since astronomers had gone so far in their enquiries concerning them, as to prove by their observations that they moved in the celestial spaces beyond the moon; but they had no notion of the path which they described. Now the power of the sun being reciprocally in the duplicate proportion of the distance, every body acted upon by him must either fall directly down or move about him in one of the conic sections. If a

body which descends towards the sun as low as the orbit of any planet, move with a swifter motion than the planet, it will describe an orbit of a more oblong figure than that of the planet, and have at least a longer axis. The velocity of the body may be so great, that it shall move in a parabola, so that having once passed the sun, it shall ascend for ever without returning, though the sun will still continue in the focus of that parabola; and with a velocity still greater, they will move in a hyperbola. The best observations, however, show that the comets move in very eccentric ellipses; and hence those bodies are sometimes found at a moderate distance from the sun, and appear within the planetary regions; at other times they ascend to vast distances, far beyond the orbit of the most distant known planet, and become invisible.

294. The analogy between the periodic times of the planets, and their distances from the sun, discovered by Kepler, of course takes place, also in the comets, at least in those which revolve in elliptic orbits; and consequently, if the periodic time of a comet were known, its mean distance might be easily computed. Now the comet of 1759 is known to perform its revolution in seventy-six years nearly, whence it appears that its mean distance is about eighteen times that of the earth, or a little less than the mean distance of Uranus; but, in consequence of the great eccentricity of its orbit, its aphelion point, or the greatest distance from the sun, is nearly double that of the above planet. The perihelion distance of this comet is about six of the mean distance of the earth, which being taken from 36, the mean transverse axis of its orbit, leaves 35.4 for its aphelion distance, which is nearly double the greatest distance of Uranus, and about four times that of Saturn.

295. The above is the only comet whose periodic return has been ascertained, till the recent re-discovery of Encke's comet, and consequently the only one whose mean distance can be known; but with regard to the perihelion distance of these bodies, this may be determined by observations; and accordingly we have an account of this element of the orbits of about 100 comets, which have been observed with considerable accuracy. The greater number of these have had their perihelion point fall within the terrestrial orbit, and many of them are such that had the mean distance of the earth; but the comet of 1680 is that of all others which approaches the nearest to the sun, its perihelion distance being only .006 of the perihelion of the earth, that is, about 540,000 miles from the sun's centre, and must, therefore, according to Newton, have been involved in its atmosphere. This comet also passed very near to the terrestrial orbit, having been, according to Dr. Hall's calculation on the 14th of November, 1680, at its distance not more than one semi-diameter of the earth, or about 4000 miles to the northward of the earth's orbit, at which time had we been in this part of our track, the comet would have had a partial eclipse of the moon; and the mutual gravitation of the two bodies must have increased the inclination of the comet's orbit, and in the length of the year; at the same time the distance from earth would have

been so elevated from the same cause, as would in all probability have caused a universal deluge, and reduced this beautiful frame to its original chaos.

296. The limits of a comet's distance may be easily ascertained from its tail, it being supposed to be directed from the sun. Let S, fig. 9, plate VI., be the sun, E the earth, ET the line in which the head of the comet appears, EW the line in which the extremity of the tail is observed, and draw ST parallel to EW; then the comet is within the distance ET. For if the comet were at T, the tail would be directed in a line parallel to EW, and therefore could never appear in that line. Now TEW is known from observation and consequently its equal ETS, together with TES, the angular distance of the comet from the sun, and ES to find ST, the limit of the comet's distance.

ON THE ORBITS OF COMETS, AND THEIR PERIODICAL REVOLUTIONS.

297. It is extremely difficult to determine from computation, the elliptic orbit of a comet to any degree of accuracy; for when this orbit is very eccentric, a very small error in the observation will change the computed orbit into a parabola, or hyperbola. Now from the thickness and inequality of the atmosphere with which the comet is surrounded, it is impossible to determine with any precision, when either the limb or centre of the comet pass the wire at the time of observation. And this uncertainty in the observations will subject the computed orbit to a great error. Hence it happened, that M. Bouguer determined the orbit of the comet in 1729 to be an hyperbola. M. Euler first determined the same for the comet in 1744; but having received more accurate observation, he found it to be an ellipse. The period of the comet in 1680 appears from observations to be 575 years, which M. Euler by his computation determined to be 166½ years.

298. The only safe way to get the period of comets, is to compare the elements of all those which have been computed, and where you find they agree very well, you may conclude that they are elements of the same comet; it being so extremely improbable that the orbits of two different comets should have the same inclinations, the same perihelion distance, and the places of the perihelion and node of the same. Thus, knowing the periodic time, we get the major axis of the ellipse, and the perihelion distance being known, the minor axis will be known. When the elements of the orbits agree the comets may be the same, although the periodic times should vary a little; as that may arise from the attraction of the bodies in our system, and which may also alter all the other elements in a small degree. The following approximating method of determining that part of a comet's orbit through which it moves, while it can be observed from the earth, is due to Boscovich.

299. Having collected the greatest possible number of observations, choose three of them which were taken when the comet was not too near its perihelion, (because near the perihelion the orbit does not differ sensibly from a circle), and

make these the basis of the operations: let S, plate VI. fig. 6, be the sun, UW the orbit of the earth, supposed here to be a circle, E the place of the earth at the first, *e* at the third, draw E, C, *e*, *c*, to represent the observed directions of the comets, and let L, *l*, *w*, be the longitudes of the first, second, and third observations, *m* and *n* the geocentric latitudes of the first and third observation, and *t*, T, the intervals of time between the first and second, second and third observations. Assume C for the place of the comet at the first observation, reduced to the ecliptic; then, to determine the place of the third observation, say $T \times \sin \overline{w-l} : t \times \sin \overline{l-L} :: EC : ec$, and *c* will be nearly the place required: join C *c*, and it will represent the path of the comet on the ecliptic, according to this assumption. Draw C K, *c* *k*, perpendicular to the ecliptic, taking CK : EC :: tang M : radius, and *c* *k* : *ec* :: tang *n* : radius; join K *k*, and it will represent the orbit of the comet, if the first assumption be true. Bisect C *c* in *x*, and draw *xy* parallel to C K, and K *k* will be bisected in *y*; join *ys*. Let SE=1; then if *v* be the mean velocity of the earth in its orbit, the velocity of the comet at $y = \frac{\sqrt{2 \times v}}{\sqrt{s y}}$ (Art. 586), taking therefore $v = Ee$, compute $\frac{\sqrt{2 \times v}}{\sqrt{s y}}$ and if this be equal to K *k*, the assumed point C was the true point.

300. But if these quantities be not equal, a new point must be assumed for C, in choosing which we must be directed by the nature and quantity of the error arising from the first assumption; thus if the computed value of K *k*, be greater than its value measured in the figure, and the lines C K, *c* *k* diverge from each other as they recede from E by how great a quantity we must conjecture from the magnitude of the error, and from the consideration that the comet's velocity diminishes as it recedes from the sun. Find C K, *c* *k*, as before, and compare the measured and computed value of K *k*; and if a fresh assumption be necessary, make it in conformity to the considerations above suggested. Having thus ascertained the position of the points C, *c*, very nearly produce C *c*, K *k* to meet at N; join N S, and it will be the line of the nodes; and if C *r*, *c* *z*, be drawn perpendicular to N S, either of the angles K *r* C, *k* *z* *c* will measure the inclination of the orbit. Also from the two distances S C, S *c*, and the included angle C S *c*, the parabola may be easily constructed; thus, having set off S C, S *c* (fig. 10, plate VI.) in their proper relative position, with the centres C, *c*, and radii equal to S C, S *c*, describe the arcs *a* R *o*, *e* *r* *i*, and draw the line R *r* *d* to touch those arcs, this line will manifestly be the directrix of the parabola: which, being known, together with the focus S and the determining ratio (that of equality), the parabola may be constructed.

301. Or, letting fall S D perpendicularly upon R D, and bisecting it in A, the vertex and focus of the parabola A *c* C will be known; whence it may be drawn by well-known methods. From either of these constructions, the ratio of the comet's perihelion distance SA (fig. 1. plate IX.)

to the earth's mean distance S E (fig. 10. plate VIII.), will be known, and consequently the comet's velocity in perihelion: the velocity in either of the points C, or *c*, will be determined by the observations; and since the angular distances are reciprocally as the squares of the distances from the centre of force, the S C, S *c*, are hence found in terms of S E: if these agree nearly with the construction, the assumptions have been properly made; if not, some farther corrections are necessary. The angles A S C, A S *c*, may either be measured or calculated from the known distances; then having the perihelion distance and the true anomaly, the time from the perihelion may be determined, whence, as the observations will show, whether the comet be approaching to, or receding from, the perihelion, an epoch of the perihelion will readily be ascertained.

302. When a parabola is found to agree nearly with the given positions, it is needless to continue the approximation farther; for if the observations are accurate, we cannot expect a parabola to agree perfectly with them; if the body move in an ellipsis, as it is highly probable that all these bodies do. If the observations are only nearly accurate, a parabola found to agree with them, might probably not agree with other observations made upon the comet.

SECT. VII.—OF THE BODIES OF THE SUN AND PLANETS, THE QUANTITY OF MATTER THEY CONTAIN, AND THEIR DENSITIES.

303. The primary planets and comets being retained in their orbits by a power directed towards the sun, and the secondaries being also retained by a similar power directed to the centre of the primaries, the same power is diffused through their whole substance, and inherent in every particle. This is proved by showing that each of the heavenly bodies attracts the rest, and other bodies, with such different degrees of force, as that the force of the same attracting body is exerted on others, exactly in proportion to the quantity of matter contained in the body attracted.

304. The first proof of this is from the experiments made on bodies on our earth. Pendulums vibrate by the same power which makes heavy bodies fall to the ground; but if the ball of any pendulum of the same length with another were more or less attracted in proportion to the quantity of solid matter it contains, that pendulum would vibrate faster or slower than the other. Now the vibrations of pendulums continue for a long time, and the number of vibrations they make may be easily and correctly determined; and Newton assures us that he examined several substances, as gold, silver, lead, glass, sand, common salt, wood, water, and wheat; in all which he found not the least deviation from the theory, though he made the experiment in such a manner that, in bodies of the same weight, a difference in the quantity of their matter less than the thousandth part of the whole would have discovered itself.

305. It appears, therefore, that all bodies are made to descend here by the power of gravity with the same degree of swiftness. This descent

has been determined at 16½ feet in a second from the beginning of their fall. If any terrestrial body could be conveyed as high as the moon, it would descend with the very same velocity as the incremental deflection of the moon towards the earth; and therefore the power of the earth upon the moon is in the same proportion to its force on other bodies at the same distance as the quantity of matter in the moon bears to the quantity in those bodies. Thus with respect to the earth, its power on every body it attracts is, at the same distance from the earth, proportional to the quantity of solid matter in the body acted upon.

306. As to the sun, the power of his action upon the same primary planet is reciprocally in the duplicate proportion of its distance; and that his power decreases throughout in the same proportion, is testified by the motion of the planets traversing the whole planetary regions. Hence if any planet were removed from the sun to any distance whatever, its tendency towards the sun would yet be reciprocally in the duplicate proportion of the distance. But the degree of acceleration given to the planets by the sun is observed to be reciprocally in the duplicate proportion of their respective distances; from this we may safely infer, that the power of the sun upon any planet removed into the place of any other, would give it the same velocity of descent as it gives that other; and consequently, that the

force of his action upon different planets at the same distance would be proportionable to the quantity of matter in each. The sun attracts the primary planets and their respective secondaries, when at the same distance, in such a manner as to communicate to both the same degree of velocity; and therefore the force wherewith the sun acts on the secondary planet, bears the same proportion to the force wherewith it attracts the primary, as the quantity of matter in the secondary planet bears to the quantity of matter in the primary.

307. This property therefore is found in the sun with regard to both kinds of planets; so that he possesses the same quality found in the earth, viz. that of acting on bodies with a degree of force proportional to the quantity of matter they contain. All the phenomena of the planetary motions produced by their mutual attractions agree precisely with this law of force; and we are therefore warranted in concluding, that this is the property which the great Author of nature has appointed to regulate the motions at least of solid matter in each kind.

308. In a word, the attractive power both of the sun and planets appears to be the same; and acts in each in the same proportion to the distance, and according to every particle of matter. Thus power then both in the sun and planets, appears to be of its nature as the power of gravity on the earth; and hence the attracting power both of the sun and planets belongs likewise to the particles of them; and their respective powers of attraction on any body are proportional to the quantity of matter of which they are composed; and therefore the force with which the earth attracts any body at the same distance, as the quantity of solid matter in the earth is to that in the sun.

309. The rule that action is equal to re-action holds good in attractive powers as well as in any other powers. The most remarkable force of this kind with which we are acquainted, next to that of gravity, is the attraction which the loadstone has for iron. Now if a loadstone and piece of iron are both made to swim on water, they move towards each other, and thus the attraction is shown to be mutual; and when they meet, they mutually stop each other; which shows that their velocities are reciprocally proportioned to the quantities of solid matter in each; and that by the stone's attracting the iron, it receives as much motion itself, in the strict philosophic sense of the word, as it communicates to the iron.

310. From this mutual action of the sun and planets upon each other, it follows, as has been already mentioned, that they both revolve about their common centre of gravity. Thus let A (in plate IX. fig. 7.) represent the sun, B a planet, and C their common centre of gravity. If these bodies were once at rest, they would directly approach each other by their mutual attraction, and that with such velocities, that their common centre of gravity would remain at rest, and they would meet in that point. Were the planet B to receive an impulse, as in the direction BE, this would prevent the two bodies from falling together; but their common centre of gravity would be put into motion in the direction of the line CF, parallel to BE. In this case, the sun and planet would describe round their common centre of gravity similar orbits, while that centre would proceed with an uniform velocity in the line CF, and so the system of the two bodies would move on with the centre of gravity without end. In order to keep the system in the same place, it is necessary, that when the planet received its impulse in the direction BE, the sun should receive such another the contrary way, so as to keep the centre of gravity, C, without any motion, in which case it would always remain fixed.

311. The action therefore between the sun and planets is mutual. The power which acts between the sun and primary planets is of the same nature with that which acts between the secondary planets and their primaries, or between the earth and bodies near its surface. In different planets the force of the sun's action upon each at the same distance, would be proportional to the quantity of solid matter contained in the planet: therefore the re-action of the planet on the sun at the same distance, or the motion which he would receive from each planet, would also be proportional to the quantity of matter in the planet; that is, these planets, at the same distance, would act on the same body, with the degrees of strength proportioned to the quantity of solid matter contained in each.

312. From these principles Newton has proved that the particles of which the sun, moon, and planets are formed, exert their power of gravitation by the same law, and in the same proportion to the distance, as the great bodies they compose.

313. The following propositions constitute the principal steps in the process of the investigation. In fig. 4, plate VI., if AB is perpendicular to AC, and a corpuscle at C is attracted

towards every particle of the line A B, by forces inversely as the squares of the distances, then the whole force which the particles in A B exert

upon C, in the direction A C, is as $\frac{AD}{CA + CD}$.

For put $AC = a$, and AD, any variable part of $AB = x$; then the force of a particle at D being as $\frac{1}{CD^2}$ in the direction D C, its force in the

direction A C, will be as $\frac{AC}{CD^3}$; or as $\frac{a}{(a^2 + x^2)^{\frac{3}{2}}}$.

Hence $\frac{a \dot{x}}{(a^2 + x^2)^{\frac{3}{2}}}$ represents the fluxion of the

whole force, whose fluent is $\frac{x}{a \cdot (a^2 + x^2)^{\frac{1}{2}}}$, or

$$\frac{AD}{CA \times CD}$$

314. Again, let B C D E, plate VI. fig. 5, represent a circular plane, and H a corpuscle perpendicularly over its centre, then if the forces with which each particle in the plane acts upon H be inversely as the squares of the distances, the force with which H will be urged towards the

plane will be represented by $\left(1 - \frac{AH}{BH}\right) 2 p$;

p being = 3.14159, &c. For let $AH = a$, and $Hl = x$; then $A b^2 = x^2 - a^2$; and $p \cdot A b^2 = p \cdot$

$x^2 - a^2$ = the area of the circle, $A c d b e$; and the fluxion of the area of this circle is $2 p x \dot{x}$. But the force of a particle at b in the direction

H A is as $\frac{AH}{H b^3}$, or $\frac{a}{x^3}$, by the preceding position; therefore the fluxion of the whole force

will be $\frac{2 a p x \dot{x} a}{x^3} = \frac{2 a p \dot{x}}{x^2}$. The fluent of this

corrected, gives $2 p \times 1 - \frac{a}{x} = 2 p \times 1 - \frac{AH}{BH}$

for the whole force.

315. To apply this to the determination of the law of force, by which a particle without a sphere would be acted upon by that sphere, the law of force of each particle in the sphere being inversely as the squares of its distance; let A B E C, plate VI. fig. 3, represent a section of a sphere of which the centre is F; let H be the particle, draw B C perpendicular to H E, join H B and

BA. Put A F = a , F H = b , A H = $b - a$ = C, H D = y and H B = $c + x$; then A D = $y - c$, E D = $2 a - y + C$, and hence

$B D^2 = A D \cdot D E = H B^2 - H D^2$, or $y - c$

$\times 2 a - y + c = c + x^2 - y^2$, an equation

from which we get $y = \frac{2 a c + 2 c^2 + 2 c x + x^2}{2 a + 2 c}$.

$= \frac{2 b c + 2 c x + x^2}{2 b}$, as $a + c = b$. Hence,

the attractive force of the particles on the circle whose diameter is B C is, by the last proportion,

$= 2 p \times 1 - \frac{H D}{H B} = 2 p \times \left(1 - \frac{2 b c + 2 c x + x^2}{2 b \times c + x^2}\right)$

$= \frac{2 p \times 2 a x - x^2}{2 b \cdot c + x^2}$; which multiplied by

$\frac{c \dot{x} + x \dot{x}}{b}$ gives $\frac{p \times 2 a x \dot{x} - \dot{x} x^2}{b^2}$ for the

fluxion of the required force, and the fluent of this expression, $\frac{p \times a x^2 - \frac{1}{3} x^3}{b^2}$ is the force of

the segment A B C, and therefore when B coincides with E, or $x = 2 a$, this expression becomes

$\frac{4 p a^3}{3 b^2}$ the attractive force of the whole sphere.

316. If the particles, of which the globe is composed, acted upon those without in the reciprocal duplicate proportion of their distances, the whole globe would hence act upon them in the same manner as it does; but, if the particles of the globe have not all of them that property,

some must act in a greater, and some in a less proportion; and if this be the condition of the globe, it is plain that when the body attracted is in such a situation in respect of the globe, that the greater number of the strongest particles are nearest to it, the body will be more forcibly attracted than when, by turning the globe about, the greater quantity of weak particles should be nearest, though the distance of the body should remain the same from the centre of the globe;

which is contrary to what was at first remarked, that the globe acts equally on all sides. If all the particles of the globe attract all the particles of another in the proportion already mentioned, the attracting globe will act upon the other in the same proportion to the distance between the centre of the globe which attracts, and the centre of that which is attracted: and the proportion holds true, though either or both of the globes be composed of dissimilar parts, some rarer, and some more dense; provided only that all the parts in the same globe, equally distant from the centre, be homogeneous, and likewise if both globes attract each other.

317. It is thus shown, that this power in the great bodies of the universe is derived from the same being lodged in every particle of the matter which composes them; and consequently that it is universal in matter, though the power is too minute to produce any visible effects on the small bodies with which we are conversant, by their action on one another. In the fixed stars indeed we have no particular proof that they have this power, as we find no appearance to demonstrate that they either act or are acted upon by it. But since this power is found to belong to all bodies whereon we can make observation, and we find that it is not altered by any change in the shape of bodies, but accompanies them in every form without diminution, being ever proportional to the quantity of solid matter in each, it is highly probable that such a power belongs universally to all matter.

318. From the times in which the satellites perform their revolutions, compared with their distances from their respective primaries, the proportion between the power with which one primary attracts his satellites, and the force with

which any other attracts his, may be found; and the proportion of the power with which any planet attracts his secondary to the power with which it attracts a body at its surface, is found by comparing the distance of the secondary planet from the centre of the primary with the distance of the primary planet's surface from the same; and from hence is deduced the proportion between the power of gravity upon the surface of one planet to the gravity upon the surface of another.

319. In a like manner by comparing the periodical time of a primary planet about the sun, with the revolution of a satellite about its primary, may be found the proportion of gravity, or of the weight of any body, on the surface of the sun, to the gravity or to the weight of the same body upon the surface of the planet which carries about the satellite.

320. Amongst the ancient mathematicians, nothing could have appeared more completely out of the reach of human intellect, than by calculation to determine the internal structure of remote and inaccessible bodies, that is, than to find the densities of the planets. Such, however, has been effected in modern times. The density of a planet can be found by comparing the velocity in its orbit round the sun with the velocity of its satellite, or by determining the distance which it deflected from its tangent in one second of time, comparing its angular velocity with the mean radius of its orbit, and by knowing the space which a heavy body falls through in one second by the force of gravity at its surface.

321. To understand the principle upon which this determination rests, we may observe that the effect of attraction at equal distances will be in

proportion to the quantity of matter in the attracting body; and at different distances, as the quantity of matter and the inverse square of the distance conjointly. The quantity of matter is also in proportion to the magnitude of the body and its density conjointly. If therefore we know the effects of the attraction of different bodies, together with their magnitudes, we can find their densities, and thence their quantities of matter.

To find their densities, put

d = the density of the celestial object,

m = its diameter,

a = its quantity of matter,

P = the periodic time of the revolving body,

D = the mean distance of the revolving body from its central body,

s = the sine of the angle under which m appears at the distance D , to radius unity.

Then a varies as $d m^3$, and P^2 varies as $\frac{D^3}{a}$, or

as $\frac{D^3}{d m^3}$; hence, d varies as $\frac{D^3}{m^3 P^2}$, but $s =$

$\frac{m}{D}$; hence, d varies as $\frac{1}{s^3 P^2}$.

From this we conclude that the logarithm of the density varies as $3 \times \log. \frac{D}{m} - 2 \log. P$. But,

in order to make the comparison between different planets as simple as possible, we shall suppose the density of the sun to be 1, and find a logarithm, which, taken from the above formula, will make it so. For this purpose we shall take the diameter of the sun = 883,217 miles, its distance from the earth 95,000,000 miles, and the earth's periodic time 365.2564 days. Hence, we have —

$$\begin{aligned} \log. D &= \log. 95000000 = 7.9777236 \\ \log. m &= \log. 883217 = 5.9460674 \end{aligned}$$

$$\frac{2.0316562}{} \times 3 = 6.0949686$$

$$\log. P = \log. 365.2564 = 2.5625978 \times 2 = 5.1251956$$

$$\frac{0.9697730}{}$$

the logarithm of the sun's density. But the logarithm of 1 is 0; hence the logarithm of the density of a planet is to that of the sun, considered as unity, as 1 to $3 \times \log. \frac{D}{m} - 2 \log. P = .9697730$.

322. To find the density of the earth, we take the moon as the revolving, and the earth as the central body. $D = 240000$, $m = 7955$, and $P = 27.32167$; and $3 \times \log. \frac{D}{m} - 2 \log. P = .9697730$ is then equal to .5959255, the log. of .39439.

To find the density of Jupiter. If we take the first satellite as the revolving body, we shall have $\frac{D}{m} = 238385$ and $P = 1.7691$; hence $3 \times \log. \frac{D}{m} - 2 \log. P = .9697730$ is then equal to 1.8916918 the log. of .7793.

324. Again, if we take the fourth satellite, we shall have $\frac{D}{m} = 12565$ and $P = 16.68898$, then $3 \times \log. \frac{D}{m} - 2 \log. P = .9697730$ is then equal to — 1.3031672 the log. of .7792.

325. To find the density of Saturn, if we take the second satellite we shall have $\frac{D}{m} = 2.75$,

and $P = 2.7368$, therefore $3 \times \log. \frac{D}{m} - 2 \log.$

$P = .9697730$ is equal to — 1.4737389, the log. of .2977. Let us take the fifth; then we have

$\frac{D}{m} = 27$, and $P = 79.3196$. Hence $3 \times \log.$

$\frac{D}{m} - 2 \log. P = .9697730$ is equal to —

1.5255573 the log. of .3354.

326. To find the density of Uranus, if we take the third satellite we shall have $\frac{D}{m} = 9.5$, and

$P = 10.9611$, then $3 \times \log. \frac{D}{m} - 2 \log. P =$

$.9697730$ is equal to — 1.8836886, the log. of 7650.

Again, let us take the sixth satellite, and we shall have $\frac{D}{m} = 44$, and $P = 107.6944$; hence,

$3 \times \log. \frac{D}{m} - 2 \log. P = .9697730$ is equal to

— 1-8961935 the log. of 7874. A trifling difference, either in the periodic time, or the distance of the satellite, will make a considerable difference in the density of the primary; and hence, if these be not very correct, the density cannot be depended on with any degree of accuracy.

327. The above are the only planets whose densities can be found by this method. Those which have no satellite, have obliged astronomers to have recourse to a method much less accurate, depending on the effect, which by observation the planet is found to produce in disturbing the motions of the other planets. Dr. Maskelyne makes the density of Venus 1.024, and M. de la Lande 1.038, that of the earth being 1. Laplace concludes the density of Mars to be .6563, and of Mercury 2.5833, the earth being 1. The density of the moon has been estimated at 1.456 times the density of the earth.

If the density of the earth be taken equal to $4\frac{1}{3}$ times that of water, we shall have the densities, or specific gravities, of the planets in the following proportions:—

Sun	1.1410	nearly =	to the specific gravity of opaque copal
Mercury	11.6250	. . .	lead
Venus	4.6395	. . .	molybdæna
Earth	4.5000	. . .	ponderous spar
Moon	6.5520	. . .	cast antimony
Mars	2.9533	. . .	flint glass
Jupiter	0.8891	. . .	mulberry tree
Saturn	0.3612	. . .	poplar
Uranus	0.8856	. . .	beech tree.

PART III.

EXPLANATION OF THE CELESTIAL PHENOMENA, ACCORDING TO THE NEWTONIAN DOCTRINE.

SECT. I.—OF THE CIRCLES, NODES, ASPECTS, CONJUNCTIONS, &c. OF THE PLANETS.

328. To a spectator placed in the sun all the planets would appear to describe circles annually in the heavens; for, though their motions are really elliptical, the eccentricity is so small, that the difference between them and true circles is not easily perceived, even on earth; and at the sun, whether great or small, it would entirely vanish. These circles, which in such a situation would appear to be annually described among the fixed stars, are called the heliocentric circles of the planets. To a spectator in the sun, the comets, though moving in the most eccentric orbits, would also appear to describe circles in the heavens: for, though their orbits are in reality very long ellipses, the planes of them extended to the heavens would mark a great circle of which the eye would be the centre; only, as the real motion is in an ellipsis, the body would appear to move much more slowly in some part of the circle than another, and to differ excessively in magnitude.

329. To an inhabitant of any planet, however, the sun appears to go round in its own heliocentric circle, or to describe in the heavens that same curve, which the planet would appear to do if seen from the sun. Thus, in plate XVI. fig. 8, when

the earth is at *a*, if we draw a line from *a* through the sun at *S*, the point *G*, in the sphere of the heavens where the line terminates, is the place where the sun then appears to an inhabitant of the earth. In a month's time the earth will go from *a* to *b*; draw a line then through the sun, and its extremity at *H* will point out his apparent place at that time. In like manner, if we draw lines from the earth in twelve several situations, in which it is represented for the twelve months of the year, the sun's apparent place will be found as above; and so it would be found by a spectator placed in Venus, or any other planet.

330. The heliocentric circle of the earth is called the ecliptic; because eclipses of the sun or moon can only happen when the latter is in or near it. By some ancient writers it has been called the circle of the sun, or the oblique circle, because it cuts the equator at oblique angles. It is also called by Ptolemy the circle which passes through the midst of the animals; because the twelve constellations through which it passes, were anciently all represented by animals, or parts of them, though now the balance is introduced in place of the claws of the scorpion. For this reason a belt, taken in the concave sphere of the heavens, about ten degrees on each side of the ecliptic, is called the zodiac, from ζῳον, an animal, and the constellations through which the ecliptic is drawn, are called the constellations of the zodiac.

331. Although the sun apparently goes round the earth annually in this circle, we cannot determine his place by mere inspection, as we can do that of any other heavenly body; for the fixed stars are the only marks by which we can determine the place of any of the celestial bodies; and the superior brightness of the sun renders them totally invisible, except in the time of a great eclipse, when his light is for a time totally obscured. But though we cannot know the place of the sun directly, it is easily found from a knowledge of those fixed stars which are opposite to him.

332. Thus, in plate IX. fig. 9, suppose it the time of the year in which the earth is at *g*, if we know that the point *G* is then diametrically opposite to the sun, we know that *A*, its opposite, is the sun's place, and consequently, by finding the places throughout the year diametrically opposite to the sun, as *GHIKLMABCDEF*, we may be assured that in these times the sun's place was in the points *ABCDEFGHIKLM*. The point in the heavens diametrically opposite to the sun may be known every night at twelve o'clock when the stars are visible; for the star which has an elevation above the horizon, at that time equal to the sun's depression below it, is directly opposite to him.

333. When the position of the ecliptic is thus determined, the latitude of the moon, or any star, is measured by its distance from the ecliptic, in the same manner as the latitudes of places on the earth are reckoned by their distance from the equator, and circles passing through the poles of the ecliptic at right angles to its plane, are called circles of latitude. The declination of any celestial body is its deviation from the equator towards the pole nearest to it.

334. The latitude of any planet is either heliocentric or geocentric. The heliocentric latitude is its distance from the ecliptic as seen from the sun, and its geocentric as seen from the earth. As the orbits of the planets are inclined in different angles to the ecliptic, the heliocentric latitude of any planet, is almost always different from its geocentric latitude. Thus, let AB, plate VII. fig. 11, be the orbit of the earth, CD the orbit of Venus, viewed with the eye in their common section, wherein they appear straight lines; let E and F be two opposite points of the ecliptic; and suppose Venus to be in the point C. If she were at that time viewed from the sun S, she would appear in the point of the heavens marked II, and her heliocentric latitude is then FH; but if viewed from the earth in B, she will appear at g; and her geocentric is only Fg.

335. The planets Mercury and Venus, whose orbits are included in that of the earth, are called inferior; and Mars, Jupiter, Saturn, and the Georgium Sidus, are called superior planets. The two points where the heliocentric circle of any planet cuts the ecliptic, are called its nodes; and that which the planet passes through as it goes into north latitude, is called the ascending node, and is marked thus γ ; and the opposite to this is called the descending node, and is marked Ω . A line drawn from one node to the other is called the line of the nodes of the planet, which is the common section of the plane of the ecliptic, and that of the planet produced on each side to the fixed stars.

336. The zodiac is either astral or local. The astral is divided into twelve unequal parts, because it contains twelve celestial constellations, some of which are larger than others. The local zodiac is divided into twelve equal parts, called signs, each containing thirty degrees. These are counted from the point where the equator and ecliptic intersect each other at the time of the vernal equinox; and are denoted by particular marks, according to the apparent annual motion of the sun. (See plate V. fig. 6.) A motion in the heavens in the order of these signs, as from Aries to Taurus, is said to be a motion in consequence; and such are the true motions of all the planets, though their apparent motions are sometimes contrary, and then they are said to move in antecedence. The local zodiac is not always invariably the same as to the places of the several signs, for the whole always takes up the same place in the heavens, viz. ten degrees on each side the equator. The points where the celestial equator cuts the ecliptic are found to have a motion in either direction of about fifty seconds a year.

337. The distance from the first point of Aries to the ascending node of a planet are counted, not only in the local zodiac, but in themselves; which is the manner in which the ancients, a few years, has nearly been discontinued. Thus, since the discovery of the heliocentric system by the Greeks, which is the manner in which the ancients counted from the first point of Aries to the ascending node of a planet, was a whole sign, and the distance from the middle of the ecliptic to the ascending node about the middle of the sign. Now, since the discovery of the heliocentric system, as still retained the old names

and marks. When the zodiac is mentioned by astronomers, the local zodiac is generally meant.

338. The longitude of a phenomenon in the heavens is in the number of degrees counted from the first point of Aries on the ecliptic to the place where a circle of latitude drawn through the phenomenon would cut the ecliptic at right angles. Every phenomenon in the heavens, whether in the zodiac or not, is thus referred to the ecliptic by its circle of latitude, or great circle, passing through the phenomenon, and cutting the ecliptic at right angles; and whatever sign the circle of latitude passes through, the phenomenon is said to have its place in that sign, though ever so far distant from it.

339. Some astronomers make the local zodiac invariable; for which purpose they imagine a circle of latitude drawn through the first star of the constellation Aries, marked in Bayer's catalogue by the Greek letter γ ; and reckon their longitude from the point where that circle cuts the ecliptic. This star is called the first star of the Ram; and, when this method is made use of, the longitude of any phenomenon is said to be so many signs, degrees, minutes, &c. from the first star of the Ram. Thus, in Street's Caroline Tables, the longitude of Jupiter's ascending node is two signs eight degrees from the first star of Aries, which is thus marked: Long. γ Ω a 1° γ 2° 8° . The common way of reckoning the longitude of a phenomenon, is to take γ for the first point of the ecliptic, and not to number the degrees quite round that circle as a continued series, but to make a new beginning at the first point of every sign, and to reckon from thence only the length of 30° . When this method is made use of, the longitude of any phenomenon is expressed by saying it is in such a degree, and such a minute of a sign: and thus we may express the longitude of the ascending node of Mercury, γ Ω γ 13° $45'$, and so of any other. The place of a phenomenon in the heavens is expressed by setting down its longitude and latitude.

340. Every planet, like the moon, is sometimes in conjunction with the sun, and sometimes in opposition. Its conjunction is when the geocentric place of the planet is the same with that of the sun; though an exact or central conjunction can only take place when the line of its nodes passes through the earth, and the planet itself is in one of its nodes at the time. It is however, in general, called a conjunction or opposition, when the same circle of latitude passes through the sun and planet at the same time. When the geocentric place of a planet is 90° , or a quarter of a circle from the sun's place, the planet is said to be in quadrature or in a quadrantal aspect with the sun; and these terms are used in a like sense when applied to any two of the heavenly bodies. Thus the sun and moon, or the moon and any planet, or any two planets, may be in conjunction, opposition, or quadrature.

341. Besides these, the ancients reckoned two other aspects, the trine and the sextile; the former when the bodies were distant 120° , and the latter when only half that distance. These aspects are marked thus:

Conjunct. Opposition Quadra. Trine Sextile
 \odot \oslash \square \triangle $*$

The aspects were formerly supposed to influence the affairs of mankind; but astrology, which treated of these influences, is now justly rejected.

342. The inferior planets have two kinds of conjunction with the sun; one in the inferior part of their semicircles, the other in the superior part. In the former the planet is between the earth and the sun; and in the latter the sun is between the earth and planet. The inferior planets can never be in opposition to the sun, nor even appear at a great distance from him. The length they go is called their elongation. Thus, in plate IX. fig. 11, let OPQRT be part of the ecliptic; S the sun; and the three circles round him the orbits of Mercury, Venus, and the earth. Suppose the earth to be at A, the sun's geocentric place will be at Q. If Mercury be then at I, his geocentric place is likewise at Q; so that he is in conjunction with the sun in his inferior semicircle: if at M, his geocentric place is likewise at Q; so that he is in conjunction in his superior semicircle.

343. In like manner, Venus at E is in conjunction in her inferior semicircle, at G in her superior: but if we suppose the earth to be at A, and Venus at H, her geocentric place is T, and her elongation QT, which in this figure is the greatest possible; for this always takes place when a straight line from the earth touches the orbit of the planet, as is evident from the figure; that is, provided the planet be in its aphelion at the time. Thus the greatest possible elongation of Mercury is QP when he is in his aphelion at L; and the quantity of this is found by astronomical observations to be about twenty-eight degrees, and that of Venus about forty-eight. The inferior planets in their elongations are sometimes eastward and sometimes westward of the sun; in the former case they appear in the evening, and in the latter in the morning. The smallness of Mercury and his nearness to the sun prevent him from being often taken notice of; but the largeness and beauty of Venus have made her, in all ages, celebrated as the evening and morning star.

344. The planets sometimes appear to go forward, sometimes backward, and sometimes to stand still. These different conditions are by astronomers called direct, retrograde, and stationary. Were they to be viewed from the sun they would always appear direct; but when viewed from the earth, the inferior planets appear direct while moving in their upper semicircles, and retrograde when in their lower ones. Thus in plate IX. fig. 11, suppose the earth at rest at A, while Mercury is going on his orbit from N to I, and from I to L, his motion appears to an observer at A to be retrograde, or contrary to the order of the signs, namely from R to Q and from Q to P; but when in that part of his orbit which lies between L and N, his motion appears direct, or from P to Q and from Q to R.

345. When the earth is in the line of nodes of an inferior planet, the apparent motion of the former is then in a straight line, because the plane of it passes through the eye; if in a conjunction in his upper semicircle, he passes behind the sun; if in his lower semicircle, he passes

before it, and will then be seen by an observer on the earth to pass over the sun's disk like a round and very black spot. Were the plane of his orbit coincident with the ecliptic, this appearance would be seen every year; but by reason of the obliquity of the two planes to each other, it is much more rare.

346. Mercury, however, was seen in this manner November 12th, 1782, at 3 h. 44 m. in the afternoon; May 4th, 1786, at 6 h. 57 m. in the morning; and December 6th, 1789, at 3 h. 55 m. in the afternoon; but was not seen again, in this island at least, until the year 1799, May 7th, at 2 h. 34 m. in the afternoon. In like manner, Venus sometimes appears as a black spot on the sun, but more seldom than Mercury. She was thus seen first in 1639; afterwards in the years 1761 and 1769; but will not again be visible in this manner till the year 1874.

347. When the earth is out of the line of the nodes of an inferior planet, its orbit appears an ellipsis, more or less eccentric, according to the situation of the eye of the spectator. In these cases the motion of Mercury is unequal; faster near the inferior conjunction, but most unequal in the inferior semicircle, going through the unequal spaces into which the ellipsis is divided. The motions of the inferior planets, both direct and retrograde, are very unequal; and this inequality proceeds not from the eccentricity of their orbits, but from the projection of their orbits into long ellipses, and is therefore a mere optical deception.

348. These planets appear stationary while changing their motion from direct to retrograde, or from retrograde to direct. If the earth stood still, the times of their appearing stationary would be at their greatest elongation; for though it be a property of the circle, that a straight line can only touch it in one point, yet when the circle is very large, the recess from the tangent is not perceptible for a considerable time. Thus in plate IX. fig. 11, suppose the earth to be at rest in A. Venus would appear stationary, her geocentric place continuing at T all the while she is going in her orbit from *a* to *b*; because her deviation from the visual line AT would scarcely be perceptible so near the point of contact H.

349. The inferior planets, therefore, to an inhabitant of the earth, appear always near the sun alternately going from and returning to him, sometimes in straight lines, at others in elliptical curves, first on one side and then on the other; sometimes so near as to be rendered invisible by his stronger light. Sometimes, when in or near their nodes, they pass behind the sun in their superior semicircles, or pass between him and us; in which case they appear like black spots on his disk, as above-mentioned. For the better comprehending of these motions, however, we have hitherto supposed the earth to stand still in some part of its orbit, while they go round the sun in theirs; but as this is not the case, it now remains to consider the changes which take place in consequence of the earth's motion.

350. Were the earth to stand still in any part of its orbit, as at A, the places of conjunction, both in the superior and inferior semicircle, as also of the greatest elongation; and consequently,

the places of direct and retrograde motion, and of the stations of an inferior planet, would always be in the same part of the heavens. Thus, in plate IX. fig. 11, upon this supposition, the places of Mercury's stations would always be the points P and R, the arc of his direct motion P R, and of his retrograde motion R P; whereas, on account of the earth's motion, the places where these appearances happen are continually advancing forward in the ecliptic, according to the order of the signs. In fig. 10, plate VIII., let A B C D be the orbit of the earth; *e f g h* that of Mercury, ☉ the sun; G F K I an arc of the ecliptic extended to the fixed stars. When the earth is at A, the sun's geocentric place is at F; and Mercury, in order to a conjunction, must be in the line A F; that is, in his orbit he must be at *f* or *h*. Suppose him to be at *f*, in his inferior semicircle; if the earth stood still at A, his next conjunction would be when he is in his superior semicircles at *h*; the places of his greatest elongation also would be at *e* and *g*, and in the ecliptic at E and G; but supposing the earth to go on in its orbit from A to B, the sun's geocentric place is now at K; and Mercury, in order to be in conjunction, ought to be in the line B K at *m*. As by the motion of the earth, the places of Mercury's conjunctions with the sun, are thus continually carried round in the ecliptic, in consequence, so the places of his utmost elongations must be carried in consequence also. Thus, when the earth is at A, the places of his greatest elongation from the sun are in the ecliptic E and G; the motion of the earth from A to B advances them forward from G to L, and from E to I.

351. The geocentric motion of Venus may be explained in a similar manner; only as the motion of Venus is much slower than that of Mercury, his conjunctions, oppositions, elongations, and stations, all return much more frequently than those of Venus.

352. To explain the stationary appearances of the planets, it must be remembered that the diameter of the earth's orbit, and even of that of Saturn, are but mere points in comparison of the distance of the fixed stars; and, therefore, any two lines, absolutely parallel, though drawn at the distance of the diameter of Saturn's orbit from each other, would if continued to the fixed stars, appear to us to terminate in the same point. Let the two circles, plate IX. fig. 4, represent the orbits of Venus and of the earth; let the lines A E, B F, C G, D H, be parallel to S P; we may nevertheless affirm that, if continued to the distance of the fixed stars, they would all terminate in the same point with the line S P. Suppose, then, Venus at E, while the earth is at A, the visual ray, by which she is seen, is in the line A E. Suppose again, that while Venus goes from E to F, the earth goes from A to B, the visual ray, by which Venus is now seen, is B F, parallel to A E; and therefore, Venus will be all that time stationary, appearing in that point of the heavens where S P extended would terminate; this station is at her changing from direct to retrograde. Again, suppose, when the earth is at C, Venus is at G, and the visual line C G; if, while the earth goes from C to D, Venus goes from G

to H, so that she is seen in the line G H, parallel to C G, she will be all that time stationary, appearing in the point where a line drawn from S through P would terminate. This station is at her changing from retrograde to direct; and both are in her inferior semicircle.

353. An inferior planet, when in conjunction with the sun, in its inferior semicircle, is said to be in perigee, and when in the other, to be in apogee, on account of its different distances from the earth. Their real distances from the earth when in perigee are variable, partly owing to the eccentricities of their orbits, as well as that of the earth; and partly owing to the motions of the different bodies, by which it happens that they are in perigee, in different parts of their orbits. The least possible distance is when the perigee happens at the time that the earth is in its perihelion, and when the planet is in its aphelion.

354. The difference of distance between the earth and inferior planets, at different times, makes a considerable variation in their apparent diameters, which indeed is very observable in all the planets; and thus, they sometimes look considerably larger than at others. This difference of magnitude in Mercury is nearly as $5\frac{1}{2}$ to 1; and in Venus, no less than 32 to 1. Any person, unassisted by instruments, may observe an inferior planet alternately approach nearer and nearer the sun, until at last it comes into conjunction with him, and then recedes farther and farther, till it is at its greatest elongation, which will be first on one side, and then on the other; but, if we observe the apparent change of place, of an inferior planet, in the sphere of the heavens, its direct motions, stations, and retrogradations, measuring its diameter frequently with the micrometer, we shall find, by its decrease at some times, and increase at others, that its distance from us is very considerably varied.

355. As the superior planets move in a larger orbit than the earth, they can only be in conjunction with the sun, when they are on that side opposite to the earth; as, on the other hand, they are in opposition to him, when the earth is between the sun and them. They are in quadrature with him, when the geocentric places are 90° distant from that of the sun. In order to understand their apparent motions, we shall suppose them to stand still, in some part of their orbit, while the earth makes a complete revolution in hers; in which case, any superior planet would then have the following appearances:

356. 1. While the earth is in her most distant semicircle, the motion of the planet will be direct. 2. While the earth is in her nearest semicircle, the planet will be retrograde. 3. While the earth is near those places of its orbit, where a line drawn from the planet would be a tangent, it would appear to be stationary. Thus, in plate VIII. fig. 6, let *a b c d* represent the orbit of the earth; S the sun; E F G an arc of the orbit of Jupiter; A B C an arc of the ecliptic, projected on the sphere of the fixed stars. Suppose Jupiter to continue at F, while the earth goes round in her orbit, according to the order of the letters *a b c d*. While the earth is in the

semicircle most distant from Jupiter, going from *a* to *b* and from *o* to *c*, his motion in the heavens would appear direct, or from A to B, and from B to C; but, while the earth is in its nearest semicircle *cde*, the motion of Jupiter would appear retrograde from C to B, and from B to A; for *a*, *b*, *c*, *d*, may be considered as so many different stations, from whence an inhabitant of the earth would view Jupiter at different seasons of the year, and a straight line drawn from each of these stations, through F the place of Jupiter, and continued to the ecliptic, would show his apparent place there to be successively at A, B, C, B, A. While the earth is near the points of contact, *a* and *c*, Jupiter would appear stationary, because the visual ray drawn through both planets, does not sensibly differ from the tangent *Fa* or *Fc*. When the earth is at *b*, a line drawn from *b* through S and F to the ecliptic, shows Jupiter to be in conjunction with the sun at B. When the earth is at *d*, a line drawn from *d* through S, continued to the ecliptic, would terminate in a point opposite to B; which shows Jupiter then to be in opposition to the sun; and thus, it appears, that his motion is direct in the conjunction, but retrograde when in opposition with the sun.

357. The direct motion of a superior planet is swifter the nearer it is to a conjunction, and slower as it approaches to a quadrature with the sun. Thus, in fig. 9, plate XIII., let ☉ be the sun; the little circle round it the orbit of the earth, whereof *abcdefg* is the most distant semicircle; OPQ, an arc of the orbit of Jupiter; and ABCDEF, an arc of the ecliptic in the sphere of the fixed stars. If we suppose Jupiter to stand still at P, by the earth's motion from *a* to *g*, he would appear to move direct from A to G, describing the unequal arcs AB, BC, CD, DE, EF, FG, in equal times. When the earth is at *d*, Jupiter is in conjunction with the sun at D, and there his direct motion is swiftest. When the earth is in that part of her orbit where a line drawn from Jupiter would touch it, as in the points *e* or *g*, Jupiter is nearly in quadrature with the sun; and the nearer the earth is to any of these points, the slower is the geocentric motion of Jupiter; for the arcs CD and DE are greater than BC or EF, and the arcs BC and EF are greater than AB or FG.

358. The retrograde motion of a superior planet is swifter the nearer it is to an opposition, and slower as it approaches to a quadrature with the sun. Thus, let ☉, fig. 10, plate XIII. be the sun, the little circle round it the orbit of the earth, whereof *ghiklmn* is the nearest semicircle; OPQ, an arc of the orbit of Jupiter, NKG an arc of the ecliptic: if we suppose Jupiter to stand still at P, by the earth's motion from *g* to *n*, he would appear to move retrograde from G to N, describing the unequal arcs GH, HI, IK, KL, LM, MN, in equal times. When the earth is at *k*, Jupiter appears at K, in opposition to the sun, and there his retrograde motion is swiftest. When the earth is either at *g* or *n*, the points of contact of the tangents *Pg* and *Pn*, Jupiter is nearly in quadrature with the sun; and the nearer he is to either of these

points, the slower is his retrogradation; for the arcs IK and KL are greater than HI or LM; and the arcs HI and KM are greater than GH or MN. Since the direct motion is swifter when the earth is at *d*, and continues diminishing till it changes to retrograde, it must be insensible near the time of change; and, in like manner, the retrograde motion being swiftest when the earth is in *k*, and diminishing gradually till it changes to direct, must also at the time of that change be insensible; for any motion gradually decreasing till it changes into a contrary one gradually increasing, must at the time of the change be altogether insensible.

359. The same changes in the apparent motions of this planet will also take place, if we suppose him to go on slowly in his orbit; only they will happen every year when the earth is in different parts of her orbit, and consequently at different times of the year. Thus, fig. 6, plate VIII., let us suppose that while the earth goes round her orbit Jupiter goes from F to G, the points of the earth's orbit from which Jupiter will now appear to be stationary, will be *a* and *y*; and consequently his stations must be at a time of the year different from the former. The conjunction of Jupiter with the sun will now be when the earth is at *f*, and his opposition when it is at *e*; for which reason these also will happen at times of the year different from those of the preceding opposition and conjunction. The motion of Saturn is so slow, that it makes but little alteration either in the times or places of his conjunction or opposition; and no doubt the same will take place in a more eminent degree in Herschel; but the motion of Mars is so much swifter than even that of Jupiter, that both the times and places of his conjunctions and oppositions are thereby very much altered.

360. A superior planet is in apogee when in conjunction with the sun, and in perigee when in opposition; and every one of the superior planets is at its least possible distance from the earth where it is in perigee and perihelion at the same time. Their apparent diameters are variable, according to their distances, like those of the inferior planets; and this, as might naturally be expected, is most remarkable in the planet Mars, who is nearest us. In his nearest approach, this planet is twenty-five times larger than when farthest off, Jupiter twice and a half, and Saturn once and a half. As the times of conjunction, utmost elongation, direct or retrograde motions of the inferior planets, depend on the combinations of their motions in their orbits with the motion of the earth in its orbit, any of these appearances will be more frequent in Mercury than in Venus, because the former moves with a swifter motion in his orbit, and consequently must more frequently pass through those places where he is in conjunction, &c.

361. The time in which any of the inferior planets will return into a given situation, may be easily known. Compute the diurnal heliocentric motions of Venus and of the earth; the difference of these motions is the diurnal motion of Venus from the earth, or the quantity by which Venus would be seen to recede from the earth every day by a spectator placed in the sun: thus

the mean motion of Venus is every day about 59 m. and 8 s.; the difference is 37 m. Therefore, as 37 m. is to 360°, or to 21,600 m. so is one day to the time wherein Venus, having left the earth, recedes from her 360°; that is, to the time wherein she returns to the earth again, or the time between two conjunctions of the same kind.

362. The calculations of the times are here made according to the mean or equable motions of the planets; and is therefore called a mean conjunction: but because Venus and the earth are really carried in elliptic orbits, in which their motions are sometimes swifter and sometimes slower, the true conjunctions may happen some days either sooner or later than what these rules will give. The time of the true conjunction is to be computed from that of the mean conjunction in the following manner. Find by astronomical tables the places of Venus and the earth in the ecliptic, from which we shall have the distance of the two as seen from the sun; compute also for the same time the angular motions of these two planets for any given time, suppose six hours; the difference of these two motions will give the access of Venus to the earth, or her recess from it in six hours. As this difference is to the arc between the places of Venus and the earth at the time of a mean conjunction, so is six hours to the time between the mean conjunction and the true. This time added to, or subtracted from, the time of the mean conjunction, according as Venus is in antecedence or consequence from the earth, shows the time of their true conjunction.

363. As to the conjunctions, oppositions, direct and retrograde motions, &c. of the superior planets, they depend on the combinations of their motions with that of the earth, and are more frequent in Saturn than in Jupiter, and in Jupiter than in Mars, but most frequent of all in Herschel; because the slower the motion of the planet is, the sooner the earth will overtake it, so as to have it again in any given situation.

364. Thus, suppose Saturn to be in conjunction with the sun in γ , if he were to stand still for one year, then he would again be in conjunction in γ ; but as he goes on slowly, according to the order of the signs, about 12° annually, the earth must go through almost 13° more than an entire revolution; so that there will be almost a year and thirteen days between any conjunction between the sun and Saturn and the conjunction immediately following. As Jupiter moves in his orbit with greater velocity than Saturn, the earth must have a proportionably larger space added to the year; and, as Mars moves swifter still, the time betwixt any two of his conjunctions must be still longer. The time when a superior planet will return into any given situation may be found by the methods already laid down for the inferior planets; and the true conjunctions, &c. may be found in the superior planets as in the inferior.

SECT. II. OF THE VELOCITY, FIGURE, MOTIONS, &c. OF THE EARTH.

365. The earth is 95,173,000 miles from the sun, and goes round in 365 days, five hours, fity-

nine minutes, from any equinox or solstice to the same again; but from any fixed star to the same again, as seen from the sun, in 365 days, six hours, nine minutes; the former being the length of the tropical year, and the latter the length of the sidereal. It travels at the rate of 68,000 miles every hour; a motion which, though upwards of 140 times swifter than that of a cannon ball, is little more than half as swift as Mercury's motion in his orbit. The earth's diameter is 7970 miles; and by turning round its axis every twenty-four hours, from west to east, it causes an apparent diurnal motion of all the heavenly bodies from east to west. By this rapid motion of the earth on its axis, the inhabitants about the equator are carried 1042 miles every hour, whilst those on the parallel of London are carried only about 580, besides the 68,000 miles by the annual motion above-mentioned, which is common to all places whatever.

366. A variety of circumstances afford the clearest evidence that the earth is of a globular figure. 1. When we are at sea on board a ship, we may be out of sight of land, when the land is near enough to be visible, if it were not hid from our eye by the convexity of the water. Thus, let ABCD, fig. 11, plate VIII., represent a portion of the globe of the earth. Let M be the top of a mountain, this cannot be seen by a person on board the ship at B, because a line drawn from M to his eye at E, is intercepted by the convexity of the water; but let the ship come to C, then the mountain will be visible, because a line may be drawn from M to his eye at E. 2. The higher the eye the farther the view will be extended. It is very common for sailors from the top of the mast of a ship, to discover land or ships at a much greater distance than they can do when they stand upon deck. 3. When we stand on shore, the highest part of a ship is visible at the greatest distance. If a ship is going from us out to sea, we shall continue to see the mast after the hull or body of the ship disappears, and the top of the mast will continue to be seen the longest. If a ship is coming towards us, the top of the mast comes first in view, and we see more and more till at last the hull appears. If the surface of the sea were a flat plain, a line might be drawn from any object situated upon it, as the ship D, fig. 12, plate VIII. to the eye, whether placed high or low, at A or B. In this case, any object upon the earth or sea would be visible at any distance which was not so great as to make the appearance of it too faint, or the angle under which it appears too small, to be seen by us. An object would be visible at the same distance, whether the eye were high or low. Not the highest, but the largest, objects would be visible to the greatest distance, so that we should be able to see the hulk of a ship farther off than the mast.

367. 4. Several navigators, such as Ferdinand Magellan, Sir Francis Drake, Lord Anson, Captain Cook, &c. have sailed round the globe; not in an exact circle, the land preventing them, but by going in and out as the shores happened to lie. 5. All the appearances in the heavens are the same, whether at land or sea. 6. Eclipses of the moon arise

from the shadow of the earth, which is always circular. Although the earth presents, during several hours, different portions of its surface to the moon, yet still the shadow is round. The small inequalities upon the surface of the earth bear no kind of proportion to its magnitude, sufficient to alter the appearance of its shadow.

368. 7. The globular figure of the earth is also inferred from the operation of levelling, in which it is found necessary, to make an allowance for the difference between the apparent and true level.

369. The earth's axis makes an angle of $23\frac{1}{2}^\circ$ with the axis of its orbit, and its position at any time is parallel to its position at any other time. Thus it points always to the same quarter of the heavens, throughout its annual course. That the earth moves round the sun may be proved, beyond a doubt, by the following arguments.

370. I. The sun is found by the most accurate observations, to be immensely larger than the earth; for his diameter, as seen by us, subtends an angle of more than $30'$, but it is certain that the earth, were it seen from the sun, would not subtend a greater angle than about $17''$. If, therefore, the sun be formed of materials not very much rarer than the earth, the quantity of matter in the sun, must far exceed the whole mass of matter in all the planets; and to suppose, that gravity retains all the other planets in their orbits, without affecting the earth, would be as absurd as to suppose, that six cannon bullets might be projected up to different heights in the air, and that five of them should fall to the ground, but that the sixth, though neither the highest nor the lowest, should remain suspended in the air without falling, and the earth move round it.

371. There is no such thing in nature as a heavy body moving round a light one as its centre of motion. A pebble fastened to a mill-stone by a string, may, by an easy impulse, be made to circulate round the mill-stone: but no impulse can make a mill-stone circulate round a loose pebble; for the mill-stone would go off, and carry the pebble along with it. The sun is so very much bigger and heavier than the earth, that, if he were moved out of his place, not only the earth, but all the other planets, if they were united into one mass, would be carried along with him as the pebble would be with the mill-stone.

372. II. If the earth revolve round the sun, then the analogy between the squares of the periodic times and the cubes of the distances, will obtain in all the bodies which circulate round a common centre; whereas, this will not be the case with respect to the sun and moon, if both turn round the earth.

373. III. Besides these, other proofs might be given; but the most complete proof of all, and which indeed amounts to a demonstration is, the aberration of the fixed stars, arising from the progressive motion of light, combined with the earth's annual motion round the sun: a discovery made by Dr. Bradley, and one of the finest in modern astronomy.

374. By frequent observations of the eclipses of Jupiter's satellites, it is found, that light is about eight minutes in moving from the sun to the earth. And since the earth describes about

one degree, or $3600''$, in a day, or $1440'$, in eight minutes it will describe $20\cdot25''$ in its orbit; therefore the velocity of light is to the velocity of the earth in its orbit, as radius to an arch of twenty seconds, or the third part of a minute, that is, as one to $\frac{0002909}{3}$ or $\cdot00009697$,

or as 10300 to one. That is, the velocity of light is 10300 times greater than the velocity of the earth in its orbit. Now if AN, plate VIII. fig. 15, be the way or path of a body in free space, as of a ray of light; its apparent way on a movable plane will be different. For it will be that which is made by the composition of the two motions of the body and plane. Thus, if AN be described in any time by the body, and NF be described by (a point in) the plane, in the same time as the plane moves forward in the direction NF or AB, it leaves all the points of the fixed line AN behind it, all which will therefore seem to move backwards in the plane. Therefore make ND=NF, being taken backwards or contrary to the motion of the plane; and the body, instead of going to N in the free space, will seem to go to D, in the same time, upon the movable plane; and therefore AD will be the apparent path of the body in that plane.

375. It will be the same thing, if we suppose the plane fixed, and the body to have the plane's motion communicated to it, in a contrary direction, so as the relative motion be the same as before. Thus, if the body moves from B to A, in the same time that it would also move from A to N, then by that compound motion it would move along the diagonal BN of the parallelogram whose sides are BA, AN, and in the same time. Therefore rays of light emitted from a star in the direction AN, will fall upon the point D of the moving plane; that is, upon the eye of the observer, in the direction AD: and an observer at D will suppose the star situated in the line DA. If BN be parallel to AD, and the point D translated to N in the same time; an observer at N will suppose the star situated in the line BN; making the angle BNF or ADF less than ANF, the angle it would appear under if the plane were at rest. So that the angle of elevation BNF, above the line of direction NE, of the observer, is less than before, being taken on the side of F, towards which the observer moves. The observer, instead of seeing the star at A, its real place, will see it at B, its apparent place; but if the observer moves from F to N and D, and B be the real place of the star, its apparent place would be at A to an observer at N.

376. The apparent place B is always in the plane of aberration, drawn through the way of the observer NF, and the line NA drawn from the observer to the real place of the star; for AB being parallel to NF, is in the plane ADFN. The angle BNA or NAD is the angle of aberration; by the quantity of this angle the star is depressed, in going towards it; or raised in going from it. In the triangle AND; AN : ND :: S.ADN : S.NAD; and AN and ND being given; the S.NAD the aberration will be as the S.ADN. Because AN is 10,300 times greater than ND: the S.NAD does not differ from its arch or angle; whence, the angle of aberration NAD or ANB is always as the sine of the angle

ADN, or ANF, which are nearly equal, and which may be called the angle of the earth's way. Hence the angle of aberration ANB is greatest, when AN is perpendicular to ND; and becomes nothing when ANF is nothing. Since AN is to ND, as radius to 20"; when AN is perpendicular to ND, the angle NAD or ANB will be 20·25", which is the greatest it can be. In other cases, as radius to S, angle of the earth's way ANF :: so 20·25", to the aberration, answering to that angle; which angle is always taken in the plane of aberration ADN.

377. In Plate VIII. fig. 7, let BCDE be the earth's orbit, S the sun, A or Q a star, N any place of the earth in its orbit. Through the star A draw the circle AH perpendicular to the plane of the ecliptic, and draw KSBI, and ESC perpendicular to it, or parallel to the tangent at B. Draw the tangent Nd, and draw NI towards the star, and make NI to Nd as the velocity of light to that of the earth, or as 10,300 to one, and draw dI which leads to the apparent place of the star; and suppose DA, SA parallel to dI, NI; then DA will also lead to the apparent place of the star. Draw SFG perpendicular to SN, or parallel to Nd. Then will INd be the plane of aberration. This plane continually changes its situation, revolving round the sun in a year along with the tangent Nd. Since AS, SF are parallel to IN, Nf; ASF is equal to INf, and ASF is equal to the angle of the earth's way. Hence the plane ASF may be taken for the plane of aberration, which continually turns round the line AS, as the earth revolves about the sun; the line SF being always in quadrature with the earth at N.

378. Let the earth be at E, then the plane of aberration ASB will be perpendicular to the ecliptic; and the angle of the earth's way ASB is the least that it can be, and the angle of the aberration the least. Whilst the earth moves to B, the angle of the earth's way, and of aberration increases, and at B the plane of aberration is ACS, and the angle of the earth's way ASC, a right angle, which is the greatest it can be; therefore the angle of aberration is the greatest possible. While the earth moves to C, the angles of the earth's way and aberration decrease

again, and at C are the least; and in moving to K they increase again to K, where they are greatest. From K to E they diminish again, where they are least.

379. It is evident then, that whilst the earth is at E moving towards N, the star's apparent place is at c lower than A; at B moving towards F, it appears at b forward. When the earth is at C, the star appears at c above A. And when the earth is at K, the star is seen at k, having gone backward. Hence the apparent place of a star describes a small ellipsis in a year, about the true place of the star in its centre, whose transverse axis is parallel to the ecliptic; and lesser axis perpendicular to it. This ellipsis is bcke, answering to places of the earth at B, C, K, E. And the points k, c, k, e, answer respectively to the points C, K, E, B, where the plane of aberration cuts the ecliptic, being ninety degrees before the earth, or ninety degrees behind the sun.

380. This phenomenon, the apparent change of place in celestial objects, arising from the combined motions of the earth and the light from those objects, is one of the most curious and important discoveries of modern times. We are indebted for it to Bradley, who, as has been well observed, 'swept the ground of astronomical discovery, and left little to be gathered by those that followed him.'

381. The following formulæ represent the effect of aberration on any fixed stars, both in right ascension and declination, μ representing 20·25" the quantity found above for the maximum effect of aberration, α and δ the right ascension and declination of the star, ω the obliquity of the ecliptic, and \odot the sun's longitude.

$$\begin{aligned} &\text{Aberration in right ascension} = -\mu. \\ &\left\{ \sin. \odot \sin. \alpha + \cos. \odot \cos. \alpha \cos. \omega \sec. \delta. \right\} \\ &\text{Aberration in declination} = -\mu. \\ &\left\{ \sin. \odot \cos. \alpha \cdot \sin. \delta - \cos. \odot (\sin. \alpha \cdot \cos. \omega \right. \\ &\quad \left. \sin. \delta - \sin. \omega \cos. \delta.) \right\} \end{aligned}$$

By the following tables, deduced from these formulæ, the effect of the aberration on the right ascension and declination of any fixed star may readily be computed.

385. *To find from these tables the aberration of a star at right ascension.*—To the logarithms of the sum or difference of the equations from tables I and II, answering to the proper arguments, add the longitude east of the star's declination, and the sum will be the logarithms of the aberration in right ascension.

386. *To find the aberration of a star in declination.*—Find the sum or difference of the equations answering to the former arguments, increased by 90°, to the logarithm of which add the logarithm sine of the star's declination, and the sum will be the logarithm of the first part of the aberration. Take parts second and third from table III, and these applied to the former, will give the aberration in declination. If the declination is south, change the sign of parts 2d and 3d.

387. The strongest objection that can be made against the earth's moving round the sun like the other planets, is, that, in opposite points of the earth's orbit, its axis, which always keeps a parallel direction, would point to different fixed stars; which is not found to be fact. But this objection is easily removed, by considering the immense distance of the stars in respect of the diameter of the earth's orbit; the latter being no more than a point when compared to the former. If we lay a ruler on the side of a table, and along the edge of the ruler view the top of a spire at ten miles distance; then lay the ruler on the opposite side of the table in a parallel situation to what it had before, and the spire will still appear along the edge of the ruler; because our eyes, even when assisted by the best instruments, are incapable of distinguishing so small a change at so great a distance. As the apparent places of the stars, therefore, correspond with this theory, the motion of the earth and the motion of light are both determined.

388. In fact, we find that the sun, and those planets on which there are visible spots, turn round their axes: for the spots in general move

regularly over their disks, allowing for the variations already taken notice of. Hence we may reasonably conclude, that the other planets, on which we see no spots, and the earth, which is likewise a planet, have such rotations. But being incapable of leaving the earth to view it at a distance, and its rotation being smooth and uniform, we can neither see it move on its axis, as we do the planets, nor feel ourselves affected by its motion. Yet there is one effect of such motion, which will enable us to judge with certainty whether the earth revolves on its axis or not.

389. All globes which do not turn round their axes, will be perfect spheres, on account of the equality of the weight of bodies on their surfaces; especially of the fluid parts. But all globes, which turn on their axes will be oblate spheroides; that is, their surfaces will be higher or farther from the centre in the equatorial than in the polar regions: for, as the equatorial parts move quickest, they will recede farthest from the axis of motion, and enlarge the equatorial diameter. That our earth is really of this figure, is demonstrable from the unequal vibrations of a pendulum, and the unequal lengths of degrees in different latitudes. Since then, the earth is higher at the equator than at the poles, the sea, which naturally runs downward, or towards the places which are nearest the centre, would run towards the polar regions, and leave the equatorial parts dry, if the centrifugal force of these parts, by which the waters were carried thither, did not keep them from returning. The earth's equatorial diameter is thirty six-miles longer than its axis.

390. One phenomenon, called the precession of the Equinoxes, depending on this peculiarity of form in the figure of the earth, has been noticed from the early ages of astronomy. The pole of the celestial equator appears to move with a slow and nearly uniform motion round the pole of the ecliptic; while the intersections of the equator and ecliptic move backward on the ecliptic, with a motion nearly uniform. This motion is at the rate of about 1° in seventy-two years, or more accurately 50·2" in a year; consequently the sun returns again to the same equinoctial point before he has completed his revolution in the ecliptic, whence the origin of the term precession of the equinoxes. In consequence of this apparent motion all the fixed stars increase their longitude 50·2" in a year, and also change their right ascensions and declinations, but their latitudes are not affected. The period of the revolution of the celestial equinoctial pole, round the pole of the ecliptic, is nearly 26,000 years.

391. The north celestial pole therefore, about 13,000 years hence, will be nearly 49° from the present polar star; and about 10000 years hence the bright star α , Syrac, will be within 5° of the north pole. This star therefore, which now in these latitudes passes the meridian within a few degrees of the zenith, will then remain nearly stationary with respect to the horizon. This motion of the celestial pole arises from the attraction of the sun and moon on the excess of matter at the equatorial parts of the earth,

392. The precession of the equinoxes is not entirely uniform, for a small inequality in the precession, and change in the obliquity of the ecliptic, depends on the position of the moon's nodes. The intersections of its orbit with the ecliptic were discovered by Bradley, and have since been confirmed by Physical Astronomy. The precession of the equinoxes was first discovered by Hipparchus. As the quantity of it is so perceptible in a hundred years, a comparison of the positions of the circles of the sphere as recorded in early times, and of their positions now, has been used to assist chronology.

393. Even the inclination of the equator and ecliptic have been shown by observation to be variable, and it is remarkable that from the date of the earliest observations that inclination has been diminishing. If it should continue to do so till the two circles coincided, a most important change would be effected in the phenomenon attending the earth's annual and diurnal revolutions, as the days would everywhere be of the same length, and the seasons would not alter with the times of the year. But we learn from the principles of physical astronomy, that this change in the obliquity will never exceed a certain limit, which when it reaches, it will return again, oscillating by a small quantity on each side of its mean state. We learn from physical astronomy too, that by this action the ecliptic is progressive on the equator, about 14" in a century. The sun also according to his place in the ecliptic produces a small inequality in the precession, never amounting to more than 1".

394. If d = the declination of a star, and a = its right ascension, then the following formulæ will express nearly the annual variations of a and b , arising from precession: $20.084'' \times \cos. a$ = the annual precession in declination, and $46.0619 + 20.084'' \times \sin. a \times \tan. d$ = the annual precession in right ascension.

395. From these expressions, the following table has been constructed for determining, by inspection, the annual precession for any star.

Rt. Ascension of		Ann. Precession.	Rt. Ascension of	
*			*	
+	-		+	-
07	130	7.0'	130°	360°
10	190	3.47	170	350
20	290	6.24	160	340
30	210	10.00	150	330
40	220	12.35	140	320
50	230	15.31	130	310
60	240	17.31	120	300
70	250	18.73	110	290
80	260	19.63	100	280
90	270	19.99	90	270

USE OF THE ABOVE TABLES.

396. Take the number opposite the star's right ascension, multiply it by the natural tangent of the star's declination, and add the product to 46.0619 for the annual precession in right

ascension. Again add 90° to the star's right ascension, and with the sum as an argument enter the table, and the corresponding number will be the annual precession in declination. If the declination is south, the signs of the numbers in the table must be changed, both in finding the precession or right ascension and declination.

397. It is found that bodies near the poles are heavier than those towards the equator, because they are nearer the earth's centre, where the whole force of the earth's attraction is accumulated. They are also heavier, because their centrifugal force is less, on account of their diurnal motion being slower. For both these reasons, bodies carried from the poles towards the equator gradually lose their weight. Experiments prove that a pendulum, which vibrates seconds near the poles, vibrates slower near the equator, which shows that it is lighter or less attracted there. To make it oscillate in the same time, it is found necessary to diminish its length. By comparing the different lengths of pendulums swinging seconds at the equator and at London, it is found that a pendulum must be $2\frac{1}{1000}$ lines (or 12th parts of an inch) shorter at the equator than at the poles.

398. A person on the earth can no more be sensible of its undisturbed motion on its axis, than one in the cabin of a ship on smooth water can be sensible of the ship's motion, when it turns gently and uniformly round. It is therefore no argument against the earth's diurnal motion, that we do not feel it; nor are the apparent revolutions of the celestial bodies every day, a proof of the reality of these motions; for whether we or they revolve, the appearance is the very same. A person looking through the cabin windows of a ship, as strongly fancies the objects on land to go round when the ship turns, as if they actually did so.

399. The other common objections against the earth's motion on its axis, are easily answered. Some imagine, that if the earth turns eastward, as it certainly does if it turns at all, a ball fired perpendicularly upward in the air should fall considerably westward of the place it was projected from. This objection will be found to have no weight, if we consider that the gun and ball partake of the earth's motion; and therefore the ball being carried forward with the air as quick as the earth and air turn, must fall down on the same place. A stone let fall from the top of a main-mast, if it meets with no obstacle, falls on the deck as near the foot of the mast when the ship sails as when it does not.

400. As for those scriptural expressions which seem to contradict the earth's motion, this general answer may be made to them all, that the scriptures were never intended to instruct us in philosophy or astronomy; and therefore, on these subjects, expressions are not always to be taken in the literal sense, but for the most part as accommodated to the common apprehensions of mankind. Men of sense in all ages, when not treating of the sciences purposely, have used common language; and it would be absurd to adopt any other in addressing the majority of mankind.

401. We have said above, that the axis of the earth preserves always the same parallel position;

but this must be understood with a slight limitation. Bradley found that the axis of the earth made a sort of conical revolution round the mean place of the pole, the earth's centre being the apex of the cone, and the diameter of the base about 18". With that admirable sagacity for which he was not less remarkable than for his accuracy and faithfulness as an observer, he clearly traced this most curious phenomena to its cause, which is the action of the sun and moon, when out of the equator, and the protuberant equatorial parts of the earth. This correction, which is called the Nutation of the earth's axis, goes through all its variations with respect to the moon in about eighteen years, the period of the revolution of the moon's nodes, and with respect to the sun in a year; but the maximum effect of the sun's action nearly amounts to half a second.

402. In strictness, however, the curve of nutation is not a circle but an ellipse, whose axes according to the best observations, are about 18" and 13.4". If Ω denote the longitude of the moon's node, r the right ascension of a star or planet, and d its declination; then the effect of the sun's nutation on the right ascension and declination will be expressed by the following formulae; viz. the nutation and declination:

$$= 7.85'' \times \sin. \overline{r - \Omega} + 1.15'' \times \sin. \overline{r + \Omega}$$

and the nutation in right ascension. $= (7.85'' \times \sin. \overline{r - \Omega} - 90^\circ + 1.15'' \times \sin. \overline{r + \Omega} - 90^\circ) + \tan d - 15.43'' \sin \Omega$.

403. From these expressions, the following tables have been computed for finding the effect of the lunar nutation on the right ascension and declination of any celestial object:

USE OF THE ABOVE TABLES.

407. To the logarithm of the sum or difference of the equations from tables I. and II., answering to their proper arguments, add the logarithm tangent of the star's declination, and the sum will be the logarithm of part first of the nutation, or right ascension if the declination is north. If it is south, change the sign and apply the equation from table III., and the sum or difference will be the nutation or right ascension. Increase the arguments in tables I. and II. each

by 90° , and the sum or difference of the corresponding difference of the equations taken from those tables, will be the nutation or declination.

408. The annual motion of the earth has been effectually confirmed by an argument drawn from the progressive motion of light; and from the same consideration the truth of the diurnal motion may be completely established.

409. In consequence of the progressive motion of light, the apparent place of a fixed star is east of its true place, and the difference is proportional to the cosine of the star's declination; this displacement of the fixed stars has changed, because of the precession of the equinoctial points. Therefore, if the diurnal revolution of the heavens were a real motion, the whole heavens must have changed their appearance; and the respective positions of the stars must be very different now, from what they were in the time of Hipparchus. A star which is now near the vernal equinox, must have changed its apparent distance, at least 5° from another ecliptical star which is 60° east from it. Nay, it is highly probable that no zodiacal star could be ever visible; such would have been the direction that the rays of light must have taken, because of their own proper motion being compounded with that of the star, whose velocity must have been exceedingly great, by reason of its distance from the poles of the motion. But since no such remarkable displacement of the stars has been observed, we may conclude, that the cause which would have produced it, has no existence; and that the revolutions of the heavens is not real, but only an apparent motion.

410. The annual and diurnal motions of the earth, together with the different lengths of days and nights, and all the beautiful variety of seasons, depending on those motions, may be thus illustrated.

411. In plate X, fig. 5, let $FGHI$ be the earth, O its centre; and let it revolve about an axis perpendicular to the plane of the figure, in the order I, G, H, F ; that is, from west to east. Let A be the sun, draw $AFOH$, and GOI perpendicular to it; let a spectator be at I ; then since the tangent at I (which represents the horizon) will be parallel to AFH , and A at an immense distance, they will nearly meet in A , and the sun at A will be rising in the horizon at I . As the earth moves round, the spectator is carried towards F , and the sun at A seems to rise higher and higher; and when the spectator is arrived at F , then the sun is at the highest. As the earth still moves round, and the spectator is carried from F towards G , the sun appears to descend, as if he moved towards D ; and when the spectator is arrived at G , then the sun appears in the tangent at G , that is, in the horizon at G ; and then the sun is setting. Afterwards, all the time the spectator is moved through GHI , the sun appears under the horizon, till it comes at I , where the sun seems to rise again.

412. From this is evident, that while the spectator is carried through the illuminated half of the earth FAG , it is day light; at the middle point F , it is noon day; at the dark hemisphere GHI , it is night; and at H , it is midnight. And thus the various shades of the moon's light appears, by the rotation of the earth about its axis. What has

been said of the sun is equally true of the moon, or any star placed at A . And therefore all the celestial bodies seem to rise and set by turns, one after another, according to their various situations. For let A, B, C, D be four stars; when the spectator is at I , the star A rises; and when at G , it sets. When the spectator is at F , B rises; and when he is at H , it sets. When he is at G , C rises; and when at I , it sets. When the spectator is at H , D rises; and when at F , it sets.

413. Hence it is the very same thing, as to the diurnal motions, whether the earth moves uniformly about its axis, while the heavens stand still; or whether the heavens move uniformly round, while the earth stands still; the phenomena being exactly the same either way. For whether the spectator move uniformly in the arch IF , from west to east, whilst A is fixed; or A moves uniformly in the arch AD , from east to west, whilst I is fixed; the same angle will be described, and therefore the altitude of A , above the horizon, will be the same either way.

SECT. III.—OF THE SEASONS.

414. To explain the causes of the various seasons in plate VII, fig. 10, let $\varphi \ominus \triangle \psi$ be the earth's orbit, and S the sun. This orbit is so small with respect to the distance of the fixed stars, that the same aspect of the heavens will appear, whether a man be placed in the earth or in the sun. If the earth be at φ , a spectator will see the sun in \triangle ; when the earth comes to ψ , he will see the sun in η ; and the sun will appear to have moved through $\triangle \eta$. Whilst the earth is moving to Π , the sun will seem to pass through $\eta \zeta$; and a person in the earth observes the sun to go through the same space in the heavens, that a spectator at the sun would see the earth go through; and as he is not sensible of the earth's motion, he ascribes that motion to the sun, which in reality is unmoved. Hence, because the relative motion is the same, whether of the two is moved, and all effects are the same as to their places; astronomers generally suppose the sun to move along the ecliptic, describing its orbit round the earth at rest.

415. Let $NEAQ$ be the earth, NA be its axis, N the north pole, A the south; $E Q$ the equinoctial, and PR a parallel of latitude passing through any place. Draw a plane $G \varphi I$ perpendicular to $\psi S \ominus$, which divides the illuminated hemisphere from the dark one. The axis NA is inclined to the plane of the ecliptic or earth's orbit, in an angle of $66\frac{1}{2}^\circ$; and during the earth's motion in its orbit, the axis always remains in a parallel position, or pointing to the same star. The earth also moves uniformly round this axis; and describes equal arches in equal times. Now let the earth be at \triangle ; in this position, the circle dividing the light and dark hemispheres passes through the poles N and A , and divides all the parallels as PR into two equal parts; therefore any point in that parallel, as the earth revolves round, will stay as long in the light hemisphere as in the dark; that is, the days and nights are equal. As it moves to η , the pole N comes into the light hemisphere, by reason of the oblique position of the axis NA ; and as it proceeds to ζ and ψ , the light hemi-

phere reaches farther and farther beyond N, till coming to ψ , it is at the farthest, reaching to G, and making the arch N G $23\frac{1}{2}^\circ$ the complement of N ψ S, or $66\frac{1}{2}^\circ$. Then the opposite pole A is as far involved in the dark hemisphere; whence in north latitudes, or in the hemisphere E N Q, the days have been increasing from \sphericalangle to ψ , where they are at their longest; for the greater part of the parallel P R is in the illuminated hemisphere, and the smaller part in the dark.

416. In the opposite or southern hemisphere the days have been decreasing, and are at their shortest when the earth is at ψ : for all parallels to E Q have their greater part in the dark hemisphere. If through the point G a parallel be described, this parallel is called the arctic circle; and all the space contained therein is illuminated, and there is no night, when the earth is at ψ . For the same reason, the space within a parallel drawn through I, will be all dark, and all is night there. If a parallel be drawn through B, where S ψ cuts the arch N E, that parallel is called the tropic of Cancer; and then the sun will shine perpendicular upon the inhabitants in that parallel. This is the summer season for those that are in the hemisphere E N Q, and the winter for those that live in E A Q; and since E Q is equally divided by the circle of light and darkness G I, the days and nights are always equal under the equinoctial.

417. While the earth moves through ω and \varkappa to φ , the circle of light and darkness comes nearer and nearer to the pole N, the angle N ψ G, and consequently B ψ E grows less and less, till they vanish in φ ; then the circle of light and darkness passes again through the poles N and A, bisecting all the parallels as P R; and the days and nights are again equal all over the earth.

418. While the earth moves through φ , δ , Π , to \ominus , the sun seems to go through \sphericalangle , η , ζ , to ψ ; and the circle separating light and darkness, falls short more and more of the north pole N, and goes further and further beyond the south pole A; whence the parallels cut by that circle will have the greater part in the dark in the north hemisphere; but in the south hemisphere, the greater part will be in the light: and it is winter to the northern hemisphere E N Q, the days being at the shortest; and summer to the southern hemisphere E A Q, their days being at the longest. Within the parallel drawn through G, there will be no day whilst the earth is at \ominus ; and in the parallel drawn through I, there will be no night. At the pole A it will be day for six months, and at the pole N it will be night for six months; just the contrary of what happens when the earth is at ψ . In this position, if a parallel be drawn through B, the sun will shine perpendicular to the earth in that parallel, and it is called the tropic of Capricorn; and a parallel drawn through I is called the antarctic circle.

419. When the earth moves from \ominus through Ω and μ to \sphericalangle again; it is evident the circle separating light and darkness draws nearer and nearer to the poles N and A, by which the light and dark parts of the parallels become nearer an equality, and so to the days and nights. Therefore in the north hemisphere E N Q, the days are increasing; and in the south hemisphere they are

decreasing: and the days and nights become equal in every place, when the earth arrives at \sphericalangle .

420. In this manner are the several seasons caused, being owing to the obliquity of the axis of rotation of the earth, to the plane of the earth's orbit. But if the axis was perpendicular to it, there could be no variety in the length of days in whatever part of the orbit the earth was; and all seasons would be alike. Thus the obliquity of the earth's axis to the ecliptic, or which is the same thing, of the equinoctial to the ecliptic; is the cause of the different seasons, summer, winter, spring, and autumn, during the year. Without this, there could be no difference of seasons; and consequently it could not be easy to know the length of the year, without observations of the stars. For the length of the year is known from finding the time by observation, when the sun is in the equinoctial points; and there being no such points to observe by, there could be no method but to observe by the position of the stars, when the same star was again in opposition to the sun, which none but an astronomer could do.

421. The sun appears 47° higher in the summer tropic than it does in the winter tropic; for in summer it seems to have ascended through the arch B E; and in winter to have descended through the arch B Q equal to B E; and their sum is 47° .

422. All these phenomena may be thus represented: Take a small globe that has the equinoctial and parallels drawn on it; and, placing a candle upon a table, move the globe round the candle in a circle parallel to the table, so that the axis of the equator may be oblique to that circle, and be kept always in a parallel position whilst it moves about. The candle will illuminate the globe as it is carried round, just as the sun does the earth in its orbit; and the poles and the parallels will be the same way affected with light and darkness as the globe.

423. The orbit of the earth being elliptical, and the sun constantly keeping in its lower focus, which is 1,617,941 miles from the middle point of the longer axis, the earth approaches twice as near, or 3,235,882 miles nearer the sun at one time of the year than at another; for the sun appearing under a larger angle in our winter than summer, proves that the earth is nearer the sun in winter. But here this question naturally arises, Why have we not the hottest weather when the earth is nearest the sun? In answer it must be observed, that the eccentricity of the earth's orbit, or 1,617,941 miles, bears no greater proportion to the earth's mean distance from the sun, than seventeen does to 1000; and therefore this small difference of distance cannot occasion any great difference of heat or cold.

424. But the principal cause of this difference is, that in winter the sun's rays fall so obliquely upon us, that any given number of them is spread over a much greater portion of the earth's surface where we live; and each point must then have fewer rays than in summer. There comes also a greater degree of cold in the long winter nights than there can return of heat in so short days; and on both these accounts the cold must increase. In summer the rays fall more perpendicularly upon us; come with greater force, and

in greater numbers, on the same place; and by their long continuance, a much greater degree of heat is imparted by day than can fly off by night.

425. Besides, those parts which are once heated, retain the heat for some time; which, with the additional heat daily imparted, makes it continue to increase though the sun declines towards the south. This is the reason why July is hotter than June; and often, in our cold climate, August hotter than both, although the sun has withdrawn from the summer tropic; as we find it is generally hotter at three in the afternoon, when the sun has gone towards the west, than at noon when he is in the meridian. Those places too which have been well cooled require time to be heated again; for the sun's rays do not heat even the surface of any body, till they have been some time upon it. Hence we find January for the most part colder than December, although the sun has withdrawn from the winter tropic, and begins to dart his beams more perpendicularly upon us. An iron bar is not heated immediately upon being put into the fire, nor grows cold till some time after it has been taken out.

426. If we suppose the degree of heat to be as m^{th} power of the sun's altitude, into the n^{th} power of the time of his continuance above the horizon, that s and c are the sine and cosine of any given latitude; s' and c' the sine and cosine of the sun's declination at the semidiurnal one; T the time in the afternoon, when the heat is the greatest; and x and y the sine and cosine of T . Then $cc' + ss'y$ will be the sine of the sun's altitude; and consequently $(cc' + ss'y)^m + \Lambda + T^n$ must be a maximum; whence its fluxion $mss'y \times \Lambda + T + nT^{n-1} + (ss' + ss'y) = 0$. But by the property of the circle $\frac{y}{x} = T$, and consequently $\frac{\Lambda + T}{m} = x - \frac{ny}{m}$; an equation from whence the relation between x and y may be determined.

427. The sun completes what is called a tropical year, when he arrives at the same equinoctial or solstitial point. This he does in 365d. 5h. 48' 57". When he arrives at the same fixed star again, as seen from the earth, he completes the sidereal year, which contains 365d. 6h. 9'. 14". The sidereal year is therefore 20' 17 $\frac{1}{2}$ " longer than the solar or tropical year, and 9' 14 $\frac{1}{2}$ " longer than the Julian or the civil year, which we state at 365d. 6h.; so that the civil year is almost a mean between the sidereal and tropical.

428. As the sun describes the whole ecliptic, or 360°, in a tropical year, he moves 59' 3" of a degree every day at a mean rate; and consequently 59' of a degree in 20' 17 $\frac{1}{2}$ " of time; therefore he will arrive at the same equinox or solstice, when he is 59' of a degree short of the same star, or fixed point in the heavens, from which he set out the year before. So that, with respect to the fixed stars, the sun and equinoctial points fall back, as it were, 30" in 2160 years, which will make the stars appear to have gone 30" forward with respect to the signs of the eclip-

tic in that time: for the same signs always keep in the same points of the ecliptic without regard to the constellations.

429. The sun returns to the equinox again in 365d. 5h. 48' and 57"; and this is the period in which the seasons complete their revolution. But as it is convenient in civil life to make the year consist of an exact number of days, three years in succession are made to consist of 365 days, and a fourth of 366 days; making the average length of a civil year to be 365d. 6h. or 11 3" too little.

430. These 11' 3", by which the civil or Julian year exceeds the solar, amount to 11 days in 1433 years; and so much our seasons had fallen back, with respect to the days of the months, since the time of the Nicene council in A. D. 325. In order, therefore, to bring back all the fasts and festivals to the days then settled, it was requisite to suppress 11 nominal days; and, that the same seasons might be kept to the same times of the year in future, to leave out the bissextile day in February, at the end of every century of years not divisible by 4; to reckon then only common years; as the 17th, 18th, and 19th centuries, viz. the years 1700, 1800, 1900, &c. because a day intercalated every fourth year was too much; and to retain the bissextile day at the end of those centuries of years which are divisible by 4, as the 16th, 20th, and 24th centuries, viz. the years 1600, 2000, 2400, &c.

431. Without these changes, the seasons in length of time would be quite reversed with regard to the months of the year; though it would have required near 23,783 years, to have brought about such a total change. If the earth had made exactly 365 $\frac{1}{4}$ diurnal rotations on its axis, while it revolved from any equinoctial or solstitial point to the same again, the civil and solar years would always have kept pace together and the style would never have needed any alteration.

SECT. IV. OF THE PHENOMENA OF THE MOON.

432. The moon is not a primary planet, but only a satellite, or attendant of the earth, circulating around it in 29d. 12h. and 44', and round the sun along with it every year. The moon's diameter is 2180 miles; and her distance from the earth's centre about 240,000 miles. She goes round her orbit in 27d. 7h. 43'. moving about 2290 miles every hour; and turns round her axis exactly in the same time that she goes round the earth, which is the reason of her keeping always the same side towards us, and that her day and night taken together is as long as our lunar month.

433. The moon is an opaque globe like the earth, and shines only by reflecting the light of the sun; therefore, whilst that half of her which is towards the sun is enlightened, the other half must be dark and invisible. Hence she disappears when she comes between us and the sun; because her dark side is then towards us. When she is gone a little way forward, we see a little of her enlightened side; which increases to our view as she advances, until she comes to be opposite to the sun; when her whole enlightened side is towards the earth, and she appears a round illuminated orb, which we call the full

Face of the Moon

moon; her dark side being then turned away from the earth. From the full she seems to decrease gradually as she goes through the other half of her course; showing us less and less of her enlightened side every day, till her next change or conjunction with the sun, when she disappears as before.

434. The moon has scarcely any difference of seasons; her axis being almost perpendicular to the ecliptic. What is very singular, one half of her has no darkness at all; the earth constantly affording it a strong light in the sun's absence; while the other half has a fortnight's darkness and a fortnight's light by turns.

435. Our earth appears as a moon to the inhabitants of the moon; waxing and waning regularly, but appearing thirteen times as big, and affording them thirteen times as much light as she does to us. When she changes to us, the earth appears full to her; and when she is in her first quarter to us, the earth is in its third quarter to her; and vice versa. But from one half of the moon the earth is never seen at all: from the middle of the other half it is always seen over head; turning round almost thirty times as quick as the moon does. From the circle which limits our view of the moon, only one half of the earth's side next her is seen; the other half being hid below the horizon of all places on that circle. To her inhabitants the earth appears the largest body in the universe; for it appears thirteen times as large as she does to us.

436. While the earth turns round its axis, the several continents, seas and islands, appear to the moon's inhabitants like so many spots of different forms and brightness, moving over its surface; but much fainter at some times than others, according as our clouds cover them. By these spots the Lunarians can determine the time of the earth's diurnal motion, just as we do the motion of the sun: and they may measure their time by the motion of the earth's spots, for they cannot have a more true dial.

437. The axis of the moon is so nearly perpendicular to the ecliptic, that the sun never removes sensibly from her equator; and the obliquity of her orbit, which is next to nothing as seen from the sun, cannot cause the sun to decline sensibly from her equator. Yet her inhabitants are not destitute of means for ascertaining the length of their year, though their method must differ from ours. We know the length of our year by the return of our equinoxes; but the Lunarians, having always equal day and night, must have recourse to another method; and, we may suppose, they measure their year by observing when either of the poles of our earth begins to be enlightened, and the other to disappear, which is always at our equinoxes; they being conveniently situated for observing great tracts of land about our earth's poles, which are entirely unknown to us. Hence we may conclude, that the year is of the same absolute length to the inhabitants of the earth and moon, though very different as to the number of days; we having $365\frac{1}{4}$ natural days, and the Lunarians only $12\frac{2}{3}$, every day and night in the moon being as long as 29 $\frac{1}{2}$ on the earth.

438. The inhabitants of the moon, on the side next the earth, may find the longitude of their places as easily as we can find the latitude of ours. For the earth keeping constantly, or very nearly so, over one meridian of the moon, the east or west distances of places from that meridian are as easily found as we can find our distance from the equator by the altitude of our celestial poles.

439. As the sun only enlightens that half of the earth which is towards him, and leaves the opposite half in darkness, he does the same to the moon; but with this difference, that as the earth is surrounded by an atmosphere, we have twilight after the sun sets; but if the moon has neither an atmosphere of her own, nor is included in that of the earth (as is supposed), the Lunarians must have an immediate transition from the brightest sunshine to the blackest darkness.

440. The moon being an opaque spherical body (for her hills take off no more from her roundness than the inequalities on the surface of an orange take of from its roundness,) we can only see that part of the enlightened half which is towards the earth. And therefore, when the moon is at A, see plate IV. fig. 3, in conjunction with the sun S, her dark half is towards the earth, and she disappears, as at *a*, there being no light on that half to render it visible. When she comes to her first octant at B, or has gone an eighth part of her orbit from her conjunction, a quarter of her enlightened side is towards the earth, and she appears horned, as at *b*. When she has gone a quarter of her orbit from between the earth and sun to C, she shows us one-half of her enlightened side, as at *c*, and we say she is a quarter old. At D she is in her second octant; and by showing us more of her enlightened side, she appears gibbous, as at *d*. At E her whole enlightened side is towards the earth; and therefore she appears round, as at *e*, when we say it is full moon. In her third octant at F, part of her dark side being towards the earth, she again appears gibbous, and is on the decrease, as at *f*. At G we see just one-half of her enlightened side; and she appears half decreased, or in her third quarter, as at *g*. At H we only see a quarter of her enlightened side, being in her fourth octant, where she appears horned, as at *h*. And at A, having completed her course from the sun to the sun again, she disappears, and we say it is new moon. Thus, in going from A to E, the moon seems continually to increase; and in going from E to A, to decrease in the same proportion; having like phases at equal distances from A to E, but as seen from the sun S, she is always full.

441. The moon does not appear perfectly round when she is full in the highest or lowest part of her orbit, because we have not a full view of her enlightened side at that time. When full, in the highest part of her orbit a small deficiency appears on her lower edge; and the contrary when full in the lowest part of her orbit.

442. From the figure it is evident, that when the moon changes to the earth, the earth appears full to the moon; and vice versa. For when the

moon is at A, new to the earth, the whole enlightened side of the earth is towards the moon; and when the moon is at E, full to the earth, its dark side is towards her. Hence a new moon answers to a full earth, and a full moon to a new earth. The quarters are also reversed to each other.

443. The position of the moon's cusps, or a right line touching the points of her horns, is very differently inclined to the horizon at different hours of the same days of her age. Sometimes she stands, as it were, upright on her lower horn, and then such a line is perpendicular to the horizon: when this happens, she is in what the astronomers call the nonagesimal degree, which is the highest point of the ecliptic above the horizon at that time, and is 90° from both sides of the horizon, where it is then cut by the ecliptic. But this never happens when the moon is on the meridian, except when she is at the very beginning of Cancer or Capricorn.

444. It is easy to demonstrate that the moon turns round her axis in the time that she goes round her orbit; for a spectator at rest, without the periphery of the moon's orbit, would see all her sides turned regularly towards him in that time. She turns round her axis from any star to the same star again, in 27d. 7h.; from the sun to the sun again in $29\frac{1}{2}$ d.; the former is the length of her sidereal day, and the latter the length of her solar day. A body moving round the sun would have a solar day in every revolution, without turning on its axis; the same as if it had been at rest, and the sun moved round it; but without turning round its axis it could never have one sidereal day, because it would always keep the same side towards any particular star.

445. If the earth had no annual motion, the moon would go round it so as to complete a lunation, a sidereal, and a solar day, all in the same time. But because the earth goes forward in its orbit, while the moon goes round the earth in her orbit, the moon must go a much more than round her orbit, from east to west, in completing a solar day, as she goes almost one forward in its orbit during that time, i. e. almost a twelfth part of a circle. If we suppose no annual motion, the moon's motion round the earth, and her track in open space, would all appear to be the same. But, as the earth and moon move round the sun, the moon's real path in the heavens is very different from her visible path round the earth; the latter being in a progressive circle, and the former in a curve of different degrees of concavity; which would always be the same in the same parts of the heavens, if the moon performed a complete number of lunations in a year without any fraction.

446. Newton ascribed the equality between the periods of rotation and revolution of the moon to her being of an oval form, and being denser on one side than the other; but La Grange has shown that though, from the diminution of the centrifugal force, the moon ought to be elevated at the equator, yet the aberration is four times as great in the direction of the equatorial diameter, as is directed towards the earth; and he has proved that, in consequence of the attraction of the sun, on this elevated

portion, the moon's motion is alternately accelerated and retarded; and that this attraction tends to produce an equality between the rotation and revolution of the moon, and to occasion a coincidence both in the position and motion of the nodes of the moon's orbit.

447. The motion of the moon in her orbit not being equable, if her rotation on her axis be uniform there must be parts on her eastern and western edges which are only occasionally seen. These changes, called her libration in longitude, are found to agree with an equable motion of rotation. There are parts also about her poles only occasionally visible. This, called her libration in latitude, arises from her axis being constantly inclined to the plane of her orbit, in an angle of about 86° . A diurnal libration also takes place; at rising a part of the western edge is seen, which is invisible at setting, and the contrary takes place with respect to the eastern edge. This is occasioned by the change of place in the spectator, occasioned by the earth's rotation. Having found by any means the moon's angular distance from the sun, the appearance of her disk for that time may be easily delineated in the following manner: Let the arch COBP, Plate IV. figs. 6 and 8, represent the disk of the moon which is turned towards the earth, and let OP be cut by the diameter BC at right angles, take LP to LF as radius to cosine of the moon's angular distance from the sun, and upon BC as the greater and LF the less axis describe the semi-ellipse BFC; then BFCP will represent that portion of the moon's illumined face which is visible from the earth.

448. To illustrate this, let the nail in the end of the axle of a chariot-wheel represent the earth, and a pin in the nave the moon: if the body of the chariot be propped up so as to keep that wheel from touching the ground, and the wheel be then turned round by hand, the pin will describe a circle both round the nail and in the space it moves through. But if the props be taken away, the horses put to, and the chariot driven over a piece of ground which is circularly convex, the nail in the axle will describe a circular curve, and the pin in the nave will still describe a circle round the progressive nail in the axle, but not in the space through which it moves. In this case, the curve described by the nail will resemble in miniature as much of the earth's annual part round the sun, as it describes whilst the moon goes as often round the earth as the pin does round the nail; and the curve described by the pin will have some resemblance to the moon's path during so many lunations.

449. The surface of the moon being uneven, some are surprised that her edge does not appear jagged, as well as the curve bounding the light and dark places. But if we consider that what we call the edge of the moon's disk is not a single line set round with mountains, in which case it would appear irregularly indented, but a large zone, having many mountains, lying behind one another from the observer's eye, we shall find that the mountains in some rows will be opposite to the vales in others; and thus fill up the inequalities so as to make her appear quite round; just as when one looks at an orange,

although its roughness be very discernible on the side next the eye, especially if the sun or a candle shines obliquely upon that side, yet the line terminating the visible part still appears smooth and even.

SECT. V. OF THE TIDES.

450. The tides are found to follow periodically the course of the sun and moon, and hence it has been suspected, in all ages, that the tides were somehow produced by the influence of these luminaries. Of this, Pliny, Ptolemy, Macrobius, and others, seem to have had some knowledge. The celebrated Kepler formed some conjectures long ago, as to the true cause of the tides. 'If,' says he, 'the earth ceased to attract its waters towards itself, all the water in the ocean would rise and flow into the moon. The sphere of the moon's attraction extends to our earth and draws up the water.' What Kepler only surmised, has been completely verified in the theory laid down by Newton, and by Halley from his principles. The principal phenomena of the tides are as follows:

451. I. The sea is observed to flow for about six hours from south to north, gradually swelling; and after a flux of about six hours, it seems to rest for a quarter of an hour; and then to ebb or retire back again from north to south for six hours more. Then, after a seeming pause of about $\frac{1}{4}$ of an hour, the sea again begins to flow; and so on alternately.

452. II. Hence the sea ebbs and flows twice a-day, but falling every day later and later by about forty-eight minutes, the period of a flux and reflux being on an average about 12 h. 24 m. and the double of each 24 h. 48 m. which is the period of a lunar day, or the time between the moon's passing a meridian and coming to it again. So that the sea flows as often as the moon passes the meridian, both the arch above the horizon, and that below it; and ebbs as often as she passes the horizon, both on the eastern and western side. These are the most obvious appearances; the other phenomena are as follows:

453. III. The elevation towards the moon exceeds the opposite one a little, and the quantity of the ascent of the water is diminished from the equator to the poles.

454. IV. The sun raises and depresses the sea twice every day, in the same manner that the moon does; but the solar tides are much less than the lunar ones, although subject to the same laws.

455. V. The tides which depend upon the actions of the sun and moon are not distinguished but compound; and thus they form to appearance one united tide which, increasing and decreasing, produce neap and spring tides.

456. VI. In the syzygies the elevations from the actions of both luminaries concur, and the sea is more elevated; but the sea ascends less in the quadratures; for where the water is elevated by the action of the moon, it is depressed by that of the sun, and vice versa. Therefore, while the moon passes from the syzygy to the quadrature, the daily elevations are continually diminished; on the contrary, they are increased

while the moon passes from the quadrature to the syzygy. At the new moon also cæteris paribus the elevations are greater; and those that follow one another the same day, are more different than those at full moon.

457. VII. The greatest elevations and depressions take place on the 2d or 3d day after the new or full moon; and they are the greater, the nearer the luminaries are to the plane of the equator; being greatest in the syzygies, near the equinoxes.

458. VIII. The actions of the sun and moon are greater the nearer those bodies are to the earth; and the greatest tides happen when the sun is a little to the south of the equator: but this does not happen regularly every year, because some variation may arise from the situation of the moon's orbit, and the distance of the syzygy from the equinox.

459. IX. The mean force of the moon to move the sea, is to that of the sun nearly as $4\frac{1}{2}$ to 1; and therefore if the action of the sun alone produce a tide of two feet, which it is said to do, then that of the moon will be nine feet; from which it follows, that the spring-tides will be eleven feet, and the neap-tides seven feet. But such elevations as far exceed these, happen from the motion of the water against some obstacles, and from the sea violently entering straits or gulfs, where the force is not broken till the water rises higher.

460. The preceding phenomena take place in the open sea, where the ocean is extended enough to be subject to their motions. But the particular situations of places, as to shores, capes, bays, &c. disturb in a considerable degree these general rules. We are now to show how these phenomena may be explained, from the principle of universal gravitation.

461. If the earth were entirely fluid and quiescent, its particles, by their mutual gravity towards each other, would form the whole mass into the figure of an exact sphere. If a power were to act on all the particles of this sphere, with an equal force, and in parallel directions, the whole mass would be moved together; but no change would be produced on its spherical figure, and its centre would have the same motion as each particle.

462. Upon this hypothesis, if the motion of the earth round the centre of gravity of the earth and moon, were destroyed, and the earth left to the influence of its gravitation towards the moon, as the power above mentioned, then the earth would fall or move straight towards the moon, without changing its spherical figure.

463. But the fact is, that the effects of the moon's action, as well as the action itself on different parts of the earth, are not equal; those parts, by the general rules of gravity, being most attracted that are nearest to the moon, and those being least attracted that are farthest from her; while the parts that are at a middle distance are attracted by a mean degree of force. Besides, all the parts are not acted upon in parallel lines, but in lines directed towards the centre of the moon, on both which accounts the spherical figure of the fluid earth must suffer some change from the action of the moon; so that in falling, as we have

supposed, the nearer parts being most attracted, would fall quickest, the farther parts being least attracted, would fall slowest, and the fluid mass would be lengthened out, and take a kind of spheroidal form.

464. Hence it appears (which must be carefully observed), that it is not the action of the moon itself, but the inequalities in that action, that cause any variation from the spherical figure; and that if this action were the same in all the particles, as in the central parts, and operating in the same direction, no such change would ensue.

465. Let us now admit the parts of the earth to gravitate towards its centre, then as this gravitation far exceeds the action of the moon, and much more exceeds the differences of her actions on different parts of the earth, the effect which results from the inequalities of these actions of the moon, will be only a small diminution of the gravity of those parts of the earth, which it endeavoured in the former supposition to separate from its centre; that is, those parts of the earth which are nearest to the moon, and those that are farthest from her, will have their gravity towards the earth somewhat abated, to say nothing of the lateral parts; so that supposing the earth fluid, the columns from the centre to the nearest, and to the farthest parts must rise, till, by their greater height, they are able to balance the other columns, whose gravity is less altered by the inequalities of the moon's action, and thus the figure of the earth must be an oblong spheroid.

466. Let us now consider the earth, instead of falling towards the moon by its gravity, as projected in any direction, so as to move round the centre of gravity of the earth and moon. it is evident, that in this case the several parts of the fluid earth will still preserve that relative position, and the figure of the earth will remain the same as if it fell freely towards the moon; that is, the earth will still assume a spheroidal form, having its longest axis directed toward the moon.

467. From the preceding reasoning, it appears, that the parts of the earth directly under the moon, as at *H*, plate X. fig. 4. and also the opposite parts at *D*, will have the flood or high-water at the same time, whilst the parts at *B* and *F*, at 90° distance, or where the moon appears in the horizon, will then have the ebbs, or lowest waters.

Hence as the earth turns round its axis from the moon to the moon again in 24h. 48m. this oval of water must shut with it, and thus there will be two tides of flood, and two of ebb in that time. It further appears, that by the motion of the earth on her axis, the most elevated part of the water is carried beyond the moon, in the direction of the rotation; so that the water continues to rise after it has passed directly under the moon, though the immediate action of the moon there begins to decrease; and comes not to its greatest elevation, till it has got about half a quadrant further. It continues to descend after it has passed at 90° from the point below the moon, to a like distance of half a quadrant.

468. The greatest elevation, therefore, is not in the line drawn through the centres of the earth and moon, nor the lowest points, where the moon

appears in the horizon, but all these are removed about half a quadrant eastward from these points in the direction of the motion of rotation. Thus, in open seas, where the water flows freely, the moon, *M*, is generally past the north and south meridian, as at *p*, when the high water is at *Z*, and at *n*; the reason of which is plain, because the moon acts with the same force after she has passed the meridian, and thus adds to the libration or waving motion which the water acquired when she was in the meridian.

469. Besides, the tides answer not always to the distance of the moon from the meridian, at the same places, for the action of the sun brings them on sooner when the moon is in her first and third quarters, and keeps them back later when she is in her second and fourth: because, in the former case, the tide, raised by the sun alone, would be earlier than that raised by the moon, and in the latter case, later.

470. We have hitherto adverted only to the action of the moon in producing the tides; but it is evident, that for the same reasons, the inequality of the sun's action on different parts of the earth, would produce a like effect, and a like deviation from an exact spherical figure; so that in reality, there are two tides, every natural day, from the action of the sun, as there are in a lunar day, from the action of the moon, subject to the same laws; and the lunar tide, as has been observed, is somewhat changed by the action of the sun, the change varying every day, on account of the inequality between the natural and lunar day.

471. Although the gravitation of the earth, towards the sun, is much greater than its gravitation towards the moon, yet, by reason of the sun's immense distance, to which the earth's diameter bears a small proportion, his action upon the side of the earth next to him differs but little from that which is exerted on the side farthest from him, and it is only the inequalities in that action that produce the tide. However, the effect of the sun is still very sensible, but that of the moon is much more so; for, by its proximity to the earth, there is a considerable inequality, both in the direction of its action, and in the intensity of that action upon different parts of the earth.

472. Hence it is easy to see, that the tides must be greatest at new and at full moon, because the actions of the sun and moon are then exerted in the same directions. These are called spring tides; whereas, when the sun and moon are 90° distant, the action of the one luminary raises the tides, just where that of the other depresses them, and thus are produced what are called neap tides. Newton has calculated the effects of the sun and moon respectively upon the tides from their attractive powers, the former he finds to be to the force of gravity, as one to 12,868,200. To find the force of the latter upon the water, he compares the spring tides at the mouth of the river Avon, below Bristol, with the neap tides, and finds the proportion as nine to five; whence, after several necessary corrections, he concludes, that the force of the moon, in moving the waters, is to that of the sun, as 4:4815 to one.

473. Dr. Horsley, however, in his edition of

Newton's *Principia*, estimates the force of the moon to that of the sun, as 5.0469 to one, and other authors have given different proportions; but Newton computes, from his proportion, that the moon may raise the waters nine feet, $1\frac{1}{2}$ inch, and the sun and moon together may produce an elevation of about eleven feet, two inches; and about $12\frac{3}{4}$ feet, when the moon is at her nearest distance. Now this is found by observation, to be nearly the height to which the water rises, on the coasts of the open and deep ocean.

474. It must be observed, that the spring tides do not happen precisely at new and full moon, nor the neap tides precisely at the quarters, but a day or two after; because, as in other cases, so in this, the effect is not greatest or least when the immediate influence of the cause is greatest or least; for if the actions of the sun and moon were to cease, yet the tides would continue for some time; as the waves of the sea continue their motion after a storm.

475. The different distances of the moon from the earth produce a sensible variation in the tides; and Newton has shown, that they increase as the cubes of the distances decrease; so that the moon at half her distance, would produce a tide eight times greater. The moon describes an oval round the earth; and at her nearest distance, produces a tide sensibly greater than at her farthest distance. Hence two great spring tides never succeed each other, at the distance of fourteen days; for if the moon be at her least distance at the change, and therefore produce a great spring tide, she will be at her greatest distance at the full, and therefore the spring tide will be less.

476. The spring tides are highest, and the neap tides lowest, about the time of the equinoxes; because, were the sun or moon in the pole of the world, there would be no tide; for their action would raise the water at the equator or any parallel, equally round the earth: therefore, the nearer they are to the equator, the greater must be the effect. When the sun and moon traverse the equator, the tides, which are under them, will traverse the greatest circle, and the waters will be put into the greatest agitation. They will also be the greater at these times, because the earth is nearer to the sun, about the beginning of March and end of September, than in the summer months.

477. As the greatest of the two tides, happening in every diurnal revolution of the moon, is that in which the moon is nearest the zenith or nadir, therefore, while the sun is in the northern signs, the greater of the two diurnal tides, in our climate, will be that arising from the moon when above the horizon; and when the sun is in the southern signs, the greatest is that arising from the moon below the horizon. Thus, the evening tides in summer exceed the morning tides, and the morning tides in winter exceed the evening tides. This difference is found at Bristol to be fifteen inches, and at Plymouth twelve inches.

478. Such would the tides regularly be, if the earth were all covered over with the sea, to a great depth, so that the waters might freely follow the influence of the sun and moon; but, as the tides pass over shoals, and run through

straits into bays of the sea, their motion becomes more various, and their height depends upon a great many circumstances. That the tides may have their full motion, the ocean, in which they are produced, ought to be at least 90° extended from east to west; because that is the distance between the greatest elevation, and the greatest depression, produced in the waters by the moon.

479. Hence it appears, that it is only in the great oceans that such tides as we have described can be produced, and why in the larger Pacific Ocean they exceed those in the Atlantic Ocean. Hence it is obvious why the tides are not so great in the torrid zone, between Africa and America, where the ocean is narrower, as in the temperate zones on either side; and hence, also, we see why the tides are so small in islands, at great distances from the shores. It likewise appears, that the waters cannot rise on one shore of the Atlantic Ocean, but by descending on the other, so that at the intermediate islands it must remain at a mean height, between its elevations on those two shores.

480. The tides that enter the mouths of rivers from the ocean, are greatly retarded in their progress, by the currents of the rivers. Mr. Condamine, while in South America, observed, that in the river Amazons, there were five high waters, and four intermediate low waters at once; and a similar circumstance takes place in the Thames. For the tide propagated by the moon in the German Ocean, when she is three hours past the meridian, takes twelve hours longer to come to London Bridge, so that when it is high water there, a new tide is already come to its height in the ocean; and in some intermediate place, it must be low water at the same time.

481. At several places, it is high water three hours before the moon comes to her meridian; but that tide, which the moon pushes as it were before her, is only the tide opposite to that which was raised by her, when she was nine hours past the opposite meridian.

482. There are no sensible tides in the Baltic, the Mediterranean, or the Black Seas; for they communicate with the ocean by such narrow inlets, and are of so immense an extent, that they cannot speedily receive and empty water enough, to raise or depress their surfaces sensibly. In the Caspian Sea, and in lakes, &c. the moon's attraction is nearly the same upon all parts of their surface, so that no sensible swelling can take place in their waters.

483. We may also conclude, that by reason of the fluidity of the atmosphere, it must have tides similar to those of the ocean; and hence, there will be a general current from east to west, both of the waters of the ocean, and of the air; but the changes produced in the state of the atmosphere, from chemical causes, will so much affect the general current, as to prevent it from being perceived.

484. We shall conclude this subject with a table, by the aid of which the time of high water may be found with great ease and correctness.

Table for finding the Time of High Water; being the Correction of the Moon's southing.

485. To find the time of high water by this table, seek in the Nautical Almanack, White's Ephemeris, or any other similar astronomical work, for the time of the moon's passing the meridian of Greenwich; with which enter the table, and take out the corresponding correction of the said time of the moon's meridian passage, and apply it by addition or subtraction as directed in the table, and add the result to the time of high water at the proposed place for the full and change days, and the sum rejecting twenty-four hours if necessary, will be the hours and minutes past noon, when it will be high water.

SECT. VI.—OF THE HARVEST MOON.

486. It is remarkable, that the moon, during the week in which she is full about the time of harvest, rises sooner after sun-set, than she does in any other full moon week throughout the year. By this means, she affords an immediate supply of light after sun-set, which is very beneficial for those employed in the harvest, and gathering in the fruits of the earth. Hence this full moon is distinguished from all others in the year, by calling it the Harvest Moon.

487. To conceive the reason of this phenomenon, it may first be considered, that the moon is always opposite to the sun when she is full, and therefore, in the harvest months, she is full in Pisces and Aries, which are opposite to Virgo and Libra, the signs occupied by the sun about the same season. Now the signs Pisces and Aries rise in a shorter space of time than others,

as is easily shown, and illustrated by a celestial globe; and the same thing may be conceived from this circumstance, that in northern latitudes, the smallest angle made by the ecliptic and horizon, is when Aries rises, at which time Libra sets; and it is obvious, that the smaller the angle contained by the ecliptic and horizon, the greater portion of the ecliptic will rise by the earth's rotation in a given time. Consequently, when the moon is full in harvest, she rises with less difference of time, or more immediately after sunset, than at any other season of the year.

488. In our winter the moon is in Pisces and Aries, about the time of her first quarter, when she rises about noon, and therefore, her rising is not then noticed.

489. In spring the moon is in Pisces and Aries about the time of her change, but as she then gives no light, and rises with the sun, her rising cannot be perceived.

490. In summer the moon is in Pisces and Aries at the time of the last quarter, and then, as she does not rise till midnight, her rising usually passes unobserved.

491. But, in autumn, the moon is in Pisces and Aries at the time of her full, and rises soon after sun-set, for several evenings successively; which makes her regular risings very conspicuous at that time of the year.

492. All this would happen, if the moon's orbit lay in the ecliptic; but her orbit makes with the ecliptic an angle of $5^{\circ} 18'$, and crosses

it in two points, called her nodes; so that her rising, when in Pisces and Aries, will sometimes not differ above an hour and forty minutes, through a whole week; and at other times, in the same two signs she will differ in a week $3\frac{1}{2}$ hours in the time of her rising, according to the different positions of the nodes with respect to the signs; which positions are always changing, because the nodes go backward through the ecliptic in eighteen years, 225 days.

493. This revolution of the nodes causes the harvest moons to go through a whole course of the most advantageous and least beneficial states, with respect to the harvest, every nineteen years. They were least beneficial in 1796, and continued so until 1797; after which, they became most beneficial from that period to 1806. In 1807 they again became least beneficial, and continued so till 1815. Their most advantageous period began again in 1816, and lasted till 1825, when the opposite period commenced, and will last until the year 1834; then again they will be most beneficial from 1835 to 1843; and so on.

SECT. VII.—OF THE HORIZONTAL SUN AND MOON.

494. Philosophers have been much at a loss to account for the apparent magnitude of the sun and moon, being greater when they are in the horizon, than when elevated above it. For, according to the laws of vision, they should appear least, when nearest the horizon, because they are then farthest from the eye; and yet, it is found, that the contrary is true, in fact. Thus, although the diameter of the moon, when in the horizon, as measured by an instrument, is not found to be greater than when measured at her greatest elevation in the meridian, yet her apparent diameter, when in the horizon, seems to the eye two or three times greater than when she is considerably elevated above it.

495. According to Alhazen, one of the earliest writers on optics, the sight apprehends the surface of the heavens as flat, and judges of the stars, as it would of ordinary objects extended upon a wide plain. The eye sees them indeed under equal angles, but at the same time perceives a difference in their distances, and (on account of the semi-diameter of the earth, which is interposed in the one case, but not in the other) it is hence induced to judge those that appear more remote to be greater.

496. Des Cartes, and from him Dr. Wallis and most other authors, account for the appearance of a different distance under the same angle, from the long series of objects interposed between the eye and the extremity of the horizon, which makes us imagine it is more remote than when in the meridian, where the eye sees nothing in the way between itself and the object. This idea of a great distance makes us imagine the luminary larger; for an object being seen under any certain angle, and believed at the same time more remote, we naturally imagine it to be very large, to appear under such an angle at such a distance, and thus a pure judgment of the mind makes us see the sun or the moon larger in the horizon than in the meridian, notwithstanding their diameters, when measured, are really less in the former situation than in the latter.

497. This opinion, however, seems hardly tenable, although it be sanctioned by the authority of very eminent men; for it is daily seen, that the sun and moon, when near the horizon, very suddenly change their magnitude as they ascend and descend, though all the intervening objects remain the same as before; and the luminaries appear largest of all, when fewest objects appear on the earth, as in a thick fog or mist.

498. Dr. Desaguliers has endeavoured to explain the appearance of the horizontal moon, on the supposition that we imagine the visible heavens to be only a small portion of a spherical surface, and consequently suppose the moon to be farther from us in the horizon than near the zenith; and he has shown how liable we are to such deceptions.

499. Upon this idea, Dr. Smith has determined, in his optics, that the centre of the apparent spherical segment of sky, lying much below the eye, the apparent distance of its parts, near the horizon, is about three or four times greater than the apparent distance of its parts over head; for which reason it is, he infers, that the moon always appears larger as she is lower, and also that we always think the height of a celestial object to be greater than it really is.

500. Of the apparent figure of the sky, we shall have occasion to treat, more fully under optics; and shall only observe here, that if it be allowed, that we judge of the apparent magnitude of the heavenly bodies, by the arc which they cover of the concave sky, it is evident, since the sky appears to us as a segment less than a hemisphere, that the horizon will appear farther distant than the zenith; and therefore the sun and moon, while in the horizon, will cover a larger portion of the apparent sky, than when more elevated, and thus their apparent diameter will be greater.

SECT. VIII.—OF THE REFRACTION OF LIGHT BY THE ATMOSPHERE.

501. If it were not for the atmosphere, the rays of light that come from the heavenly bodies, and by which they are seen, would enter the eye in the direction of a straight line joining the luminous body and the eye. But the earth being covered to a considerable height with an atmosphere of unequal density, a ray of light falling obliquely upon its surface, instead of continuing to move forward in the same rectilinear direction, is bent downwards into a curve, in its future progress; and enters the eye in a direction differing more or less from its original one, according as it falls upon the atmosphere, with a greater or less degree of obliquity.

502. This effect may be thus illustrated: Suppose ZY, plate IV. fig. 7, a quadrant of a vertical circle described from the centre of the earth T, under which is AB a quadrant of a circle on the surface of the earth, and GH a quadrant of the surface of the atmosphere. Then suppose SE a ray of light emitted from a star at S, and falling on the atmosphere at E; because the ray passes out of a rare medium (and most probably a perfect vacuum) into a denser medium; by the laws of optics, it will be refracted towards the perpendicular, or more inclined towards the earth; and since the

further that a ray descends in the atmosphere, the more dense is the medium through which it passes, it will move in the curve EA, and at last enter the eye in the direction of AFQ, a tangent to the curve. Therefore the star will appear at Q instead of S, and thus its apparent place Q will be nearer the zenith than its true place.

503. The nearer the star S is to the horizon, the greater will be the refraction as well as the distance between the apparent and true place of the star. Hence the heavenly bodies appear to be above the horizon, by reason of the refraction, when they are really below it. There is no refraction in the zenith, for a ray, coming from Z, will fall perpendicularly on the surface of the atmosphere at G, and continue its rectilinear course to the eye at A.

The following neat and elegant method of computing the atmospheric refraction has been given by Dr. Brinkley, the present learned and active professor of astronomy at Dublin:

504. Let LI, fig. 7, plate VI, be a ray of light falling on the atmosphere at L, and refracted in the curvilinear course IS. The object appears to a spectator at S in the direction ST, a tangent to the curve, VST is the apparent zenith distance. The space in the figure between the concentric circles represents all the atmosphere which has any effect on the ray of light, so that the light may be considered as passing out of a vacuum into this space.

505. If the surface of the earth were a plane, the different strata of air might be considered as parallel thereto: and by the principles of optics, the refraction would be the same as would take place were the ray of light to pass from a vacuum into air of the same density with that at the surface. It is therefore evident, that if we take into account the spherical form of the earth and atmosphere, the error resulting from the supposition of an uniform atmosphere will necessarily be very small, compared with the change occasioned by considering the atmosphere spherical, provided that change be small.

506. Let $m : 1 :: \sin. \text{ of incidence} : \sin. \text{ of refraction}$, when a ray of light passes from a vacuum into air of the density of that at the surface of the earth. Suppose all the air contracted into an uniform atmosphere, then SI is a right line. Let $III. = i$, $SIC = r$, $VSI = z$, $SC = a$, the height of the uniform atmosphere = l , or $CI = a + l$.

$$\begin{aligned} a + l : a :: \sin. z : \sin. r \\ 1 : m :: \sin. r : \sin. i. \end{aligned}$$

Hence

$$\sin. i = \frac{ma \sin. z}{a + l} = m \sin. z \left(1 - \frac{l}{a} \right) \text{ nearly.}$$

$$\sin. r = \frac{a \sin. i}{a + l} = \sin. z \left(1 - \frac{l}{a} \right) \text{ nearly.}$$

Let $i = r + R$, then R is the quantity of refraction. $\sin. (r + R) = \sin. i$. Or, because R is small, $\sin. r + \cos. r \sin. R = \sin. i$, or $\sin. r + R \sin. 1'' \cos. r = \sin. i$, substituting in this equation for $\sin. r$ and $\sin. i$, as above. Also for $\cos. r$.

$$\sqrt{1 - \sin.^2 z \left(1 - \frac{l}{a} \right)^2} =$$

$$\sqrt{\cos.^2 z + \frac{z l}{a} \sin.^2 z} =$$

$$\cos. z \left(1 + \frac{l}{a} \tan.^2 z \right)$$

nearly, we obtain

$$\begin{aligned} R = \frac{\sin. i - \sin. r}{\sin. 1'' \cos. r} &= \frac{m - 1 \cdot \sin. z \cdot \left(1 - \frac{l}{a} \right)}{\sin. 1'' \cos. z \left(1 + \frac{l}{a} \tan.^2 z \right)} \\ &= \frac{(m - 1) \tan. z}{\sin. 1''} - \frac{(m - 1) l \tan. z^2}{a \sin. 1'' \cos. z^2} \text{ nearly.} \end{aligned}$$

507. Taking $z = 80^\circ$, $2 = 5$ and $a = 4000$ miles, the second term (arising from the spherical figure of the atmosphere) = $10''$ nearly. If a were indefinite, that is, if the surface of the earth were a plane, this second term would vanish. Hence we may safely conclude, that as far as 80 zenith distance, the error arising from supposing the atmosphere of uniform density must be much less than $10''$, and that consequently the above expression gives the refraction as far as 80 from the zenith with sufficient accuracy. If we neglect the second term, the refraction will vary as the tangent of the zenith distance.

508. The exact experiments of M. M. Biot and Arago, have determined the value of $m - 1 = .0002946$, when the barometer is at 29,93 (in metre) and Fah. therm. at 32° . From their experiments, and the law of expansion of air, it

may be inferred that $\frac{m - 1}{\sin. 1''} = \frac{1,0375}{1 + .002083 (t - 32)} \times \frac{b}{29,60} \times 57'' 82$, nearly where b is height of the barometer, and t that of Fahrenheit's thermometer. When $t = 50^\circ$ and $b = 29,60$ inches, this expression gives $\frac{m - 1}{\sin. 1''} = 57.82$, a result independent of astronomical observations.

509. The French tables of refraction, by Delambre, founded on astronomical observations, give $\frac{m - 1}{\sin. 1''} = 57.72''$; and from upwards of 500 observations made by himself, Dr. Brinkley finds $\frac{m - 1}{\sin. 1''} = 57.56''$.

510. Mr. H. Atkinson, in a memoir recently read before the Astronomical Society of London, and printed in the forth-coming part of the Society's Memoirs, has treated the subject of refractions in a manner altogether new; and has evinced talents for scientific investigation which place him in a high rank among the philosophers of the present day. He treats the question altogether as one depending on the optical properties of air, by dividing the whole atmosphere into various concentric strata, and computes the deviation produced by refraction on each stratum. We should be glad, did our limits permit us, to quote very largely from this most elaborate and instructive essay, but we must content ourselves with extracting one of the results of his labours in a table of mean refraction.

511. Table of Mean Refraction, adapted to 50° Fahrenheit, and 29.6 inches of Barometric pressure.

512. This refraction of the light by the atmosphere produces the twilight; for while the sun is less than 18° below the horizon, his rays, although prevented from reaching us directly, by reason of the interposed body of the earth, yet fall upon the superior regions of the atmosphere, and are so refracted and reflected by its particles as to produce a brightness over the horizon, which continues through the whole night during the summer months, in the regions of the earth towards the poles.

513. The subject of twilights has given rise to a problem which, from the talents of the mathematicians who have applied themselves to its investigation, has obtained considerable celebrity. The problem is, to find the day in any given latitude in which the twilight is the shortest. It might be imagined that the twilights would increase from midsummer to midwinter; but this both observation and theory show not to be the case; for though the twilights continue to increase in duration for some time after the sun's declination, allowed a denomination different from the latitude, yet they reach a maximum, after which they again increase.

514. In fig. 11, plate VI, let P be the pole, Z the zenith, HO the horizon, AL the boundary of twilight, Ss the places of the sun at the beginning and end of twilight. Draw the great circles PS, Ps, ZS, and Zs, also PR = ZP, making the angle ZPR = ∠SPs, and complete the triangle ZRs with great circles ZR, RS. Then as the ∠ZPR = ∠SPs, we have the ∠RPs = ∠ZPs; also, since Ps = PS, and PR = PZ, the triangles RPs, ZPs, are similar and equal: therefore Rs = Zs, and in the triangle ZRs we have given ZS and Rs, and as ZP, RPs are equal and given, and the ∠ZPR = ∠SPs a minimum, we shall have ZR the least possible, which by the writers on spherics it is shown to be when Zs = Rs, Rs coincide: hence the following

CO-SINE-PROX.—With ZP, r P, each = colat of the place, and ZR = Zs = Rs (ZS) = 18°; describe the isosceles triangle ZPr prolong Zr making rs = ZS = 90, draw Pz, which is the co-declination of the sun on the required day.

515. CALCULATION.—Draw Pz perpendicular and bisecting Zr in z, then, by spherical trigonometry, we have cos. zr : rad. 1 :: cos. Pr : cos. Pz, or cos. Pz = $\frac{\cos. Pr}{\cos. zr}$; and in the triangle zPs, as rad. 1 : cos. Pz :: cos. Pz = $\frac{\cos. Pr}{\cos. zr}$, or sin. docl. = $\frac{\cos. zS \times \cos. Pr}{\cos. zr}$

$$= \frac{\cos. 90^\circ \times \text{ sine lat.}}{\cos. 9^\circ} = -\frac{\text{ sine } 9^\circ \times \text{ sine lat.}}{\cos. 9^\circ}$$

= - tang. 9° × sine lat. A simple and general theorem, from which it appears that the declination and latitude are of contrary names. From this theorem it appears, that the shortest twilight at Petersburg is about October 14th; at London, October 14th, and at Rome, October 9th.

516. The rays of light are equally refracted by the atmosphere, whether they come from the sun, the moon, or the stars; but the quantity of the refraction, and therefore the duration of the twilight, are influenced by the changes which are

perpetually taking place with respect to the heat and cold, the moisture and dryness, &c. of the atmosphere.

PART IV.

ASTRONOMICAL OPERATIONS AND CALCULATIONS.

SECT. I.—OF DRAWING A MERIDIAN LINE.

517. Upon a plain board, set parallel to the horizon, describe a circle ABF, as in plate VIII. fig. 2. And upon the centre C, erect a stile or gnomon, exactly perpendicular to it, and so high, that the top of the shadow thereof may fall upon the circumference of the circle about the middle of the forenoon. Mark the point B exactly where the top of the shadow falls in the forenoon, and the point F where the top of the shadow falls on the circumference, in the middle of the afternoon. Then, through the centre C, draw the line ACD, bisecting the arch BF. The AD is the meridian required.

518. It is proper to draw several concentric circles, and to make observations with them all, that they may confirm one another. If the sun happens to be clouded in one, it may be clear in another. It is best to make these observations about the solstices, when the sun does not alter his declination sensibly; and the summer solstice is to be preferred.

519. The sun is evidently highest when in the meridian; and at equal distances therefrom has equal altitudes. Therefore, when the distances DB, DF, are equal, the shadows CB, CF, will be equal, and therefore the altitudes equal. And vice versa.

520. 2. Hang up two threads and plumbets AB, CD, plate VIII. fig. 13, at a good distance, in vessels of water, to keep them steady; of which C D is movable towards the left and right, upon a pin C. Wait till the polar star, E, and the star Alioth, F, (in the great bear's rump), come into the same plumb line, AB, to an eye placed at I. At that instant (or rather before) move the thread CD also into the same line; so that the thread CD may hide the thread AB, and the polar star E from the eye at I. Then the plane ABCD is the plane of the meridian; and where it intersects the horizontal plane, is the meridian line. And the same may be done with the star, called Cassiopeia's hip. To take away the star's rays, look through a small hole in a thin plate. This must be performed in a calm place.

521. If it is wished to have a meridian drawn in some other place, let the threads and plumbets AB, CD, remain; and hang up two others ab, cd, in the place proposed, as in fig. 14, letting ab be movable upon a pin at a. Then wait till any star, as G, comes into the plane abcd to the eye, at h; and at that instant, move the thread ab, till the same star G fall in the plane abcd, to the eye at h; then abcd is the plane of the meridian. This is best done by the help of an assistant. This method will in time deviate a little from the truth, occasioned by the stars changing their places; but that change is very inconsiderable for several years.

522. 3. Having a clock or watch, with minutes and seconds, find the northing of the star, Alioth, F, fig. 13, by the astronomical tables; and

wait till the polar star E is in a plumb line with F. At that instant, set the clock to the said time of nothing. And next day at twelve o'clock, draw a meridian line, by the shadow of a plumb line hung in the sun. Or find the time of southing of any other star, as G, and the clock remaining as before, when she shows the time of southing, place the threads *ab, cd*, fig. 14, so that the line *Gh* may pass through them both. Then *abcd* will be in the plane of the meridian.

523. These methods are only to be considered as affording a first and very rough approximation to the meridian, and may assist in placing a transit instrument nearly in its position with respect to the meridian, previously to the application of the more exact methods by which the final adjustment is made.

SECT. II.—OF FINDING TIME, AND THE EQUATION OF TIME.

524. Having drawn a meridian line, as directed in the last article, the time when the sun, or any other celestial body is exactly in the meridian, may be found by a common quadrant, placing the edge of it along the line, and observing when the sun or other luminary can be seen exactly through its two sights, and noting exactly the time; which, supposing the luminary viewed to be the sun, will be precisely noon, or twelve o'clock: but, as the apparent diameter of the sun is pretty large, it ought to be known exactly when his centre is in the meridian, which will be some short space after his eastern limb has arrived at it, and before his western limb comes thither. It will be proper, therefore, to observe exactly the time of the two limbs being seen through the sights of the quadrant; and the half of the difference between these times, added to the one or subtracted from the other, will give the exact time when the sun's centre is in the meridian.

525. The same method is equally applicable to the moon; but not to the stars, which have no sensible diameter. It is found, by observation, that the stars appear to go round the earth in twenty-three hours, fifty-six minutes, four seconds, and the sun in twenty-four hours; so that the stars gain three minutes, fifty-six seconds upon the sun every day, which amounts to one diurnal revolution in a year; and therefore, in 365 days, as measured by the returns of the sun to the meridian, there are 366 days as measured by the stars returning to it: the former are called solar days, and the latter sidereal.

526. These may be considered as first steps in the determination of this important element. With the aid of a transit instrument, the time can always be determined with the greatest simplicity and exactness. But supposing the latitude of the place of observation to be known, the time may be deduced with great ease and precision from the altitude of any celestial object observed with a quadrant or sextant, taken by reflection from a basin of water or quicksilver. Equal altitudes of stars, perhaps, furnish the most ready and convenient method of determining the time, as the use of trigonometrical formulæ is not required; and there is besides no farther dependence on the goodness of the instrument, than that it shall be in the same state at both observations.

527. As we shall have occasion, when treating of Nautical Astronomy (which we shall do under the article NAVIGATION), to explain the various ways by which time may be found, and consequently, how clocks may be regulated, we shall here merely give the practical method of finding the error of a clock by equal altitudes of fixed stars.

528. Take the altitude of a star when eastward of the meridian, and mark the time by the clock when the observation is made; wait till the star when west of the meridian comes to the same altitude, and mark the time by the clock. Half the sum of these times will be the time by the clock when the star is on the meridian. Now the sidereal time at which a star is on the meridian is equal to the star's right ascension; and the solar or apparent time is obtained by subtracting the sun's right ascension from the star's. Hence the error of the clock, either for mean or sidereal time, is obtained at once. In practice, however, it is preferable to take several altitudes, and their corresponding times, both eastward and westward of the meridian, and to take half the sum of the mean of the times for the time by the chronometer at which the star passes the meridian.

529. For example, suppose that on February 20th, 1826, the time at which Regulus had the following altitudes, was as under:

Times E. of the merid.			Alts.	Times W. of the merid.		
h.	m.	s.		h.	m.	s.
9	4	26	. 38° 0'	16	43	14
	5	14	. 10'		42	26
	6	7	. 20'		41	31
	6	58	. 30'		40	43
<hr/>				<hr/>		
9	5	41.25 mean.		16	41	58.5
<hr/>				<hr/>		
				9	5	41.25
				<hr/>		
				25	47	39.75
				<hr/>		
				12	53	49.87 Time

by the chronometer when the star is on the meridian. Hence by comparing this with the star's right ascension on the same day (9 h. 59 m. 8.8 s.), it is found that the watch is 2h. 54m. 41.07 s. fast for sidereal time.

530. If the earth had no annual motion, but only a diurnal, any given meridian would revolve from the sun to the sun again, in the same quantity of time as from any star to the same star again; because the sun would never change his place with respect to the stars. But, as the earth advances almost a degree eastward in its orbit, in the time that it turns eastward round its axis, whatever star passes over the meridian on any day with the sun, will pass over the same meridian on the next day, when the sun is almost a degree short of it; that is, three minutes, fifty-six seconds sooner. If the year contained only 360 days, as the ecliptic does 360 degrees, the sun's apparent place, so far as his motion is equable, would change a degree every day; and then the sidereal days would be just four minutes shorter than the solar.

531. As the motion of the earth round its axis is perfectly uniform and equal at all times of the year, the sidereal days are always precisely of an

equal length; and so would the solar or natural days be, if the earth's orbit were a perfect circle, and its axis perpendicular to its orbit. But the earth's diurnal motion on an inclined axis, and its annual motion in an elliptic orbit, cause the sun's apparent motion in the heavens to be unequal: for sometimes he revolves from the meridian to the meridian again in somewhat less than twenty-four hours, shewn by a well-regulated clock; and at other times in somewhat more: so that the time shewn by a good clock and a true sun-dial is never exactly the same, excepting on the 15th of April, the 16th of June, the 31st of August, and the 24th of December. The clock, if it goes equably and true all the year round, will be before the sun from the 24th of December till the 15th of April; from that time till the 16th of June, the sun will be before the clock; from the 16th of June till the 31st of August, the clock will be again before the sun; and from thence to the 24th of December, the sun will be faster than the clock.

532. The equation of time, therefore, or difference between the time shewn by a well-regulated clock and a true sun-dial, depending upon two causes, viz. the obliquity of the ecliptic, and the unequal motion of the earth in it, the united effects, resulting from their combination, may be explained in the following manner:—

533. Let $Z \varphi z \simeq$, in plate V, fig. 1, be the earth; $ZFRz$, its axis; $abcdc$, &c. the equator; $ABCDE$, &c. the northern half of the ecliptic from φ to \simeq on the side of the globe next the eye; and $MNOP$, &c. the southern half on the opposite side from \simeq to φ . Let us suppose a fictitious sun to set out from φ , at the same instant with the real sun. Let the points at $ABCDEFGHI$, &c. quite round, from φ to φ again, bound equal portions of the ecliptic, gone through in equal times by the real sun; and those at $abcdefg$, &c. equal portions of the equator described in equal times by the fictitious sun; and let $Z \varphi z$ be the meridian.

534. As the real sun moves obliquely in the ecliptic, and the fictitious sun directly in the equator, with respect to the meridian; a degree, or any number of degrees, between φ and F on the ecliptic, must be nearer the meridian $Z \varphi z$, than a degree, or any corresponding number of degrees, on the equator from φ to f ; and the more so, as they are the more oblique: and therefore the true sun comes sooner to the meridian every day, whilst he is in the quadrant φF , than the fictitious sun does in the quadrant φf ; for which reason, the solar noon precedes noon by the clock, until the real sun comes to F , and the fictitious to f ; which two points, being equidistant from the meridian, both suns will come to it precisely at noon by the clock.

535. While the real sun describes the second quadrant of the ecliptic $FGHIK$, from Cancer to \simeq , he comes later to the meridian every day, than the fictitious sun moving through the second quadrant of the equator, from f to \simeq ; for the points at $GHIK$, and L , being farther from the meridian, their corresponding points at ghk and l , must be later in coming to it: and as both suns come at the same moment to the point \simeq , they come to the meridian at the moment of noon by the clock.

536. In departing from Libra, through the third quadrant, the real sun going through MN OPQ towards φ at R , and the fictitious sun through mno p q towards r , the former comes to the meridian every day sooner than the latter until the real sun comes to φ , and the fictitious to r , and then they come both to the meridian at the same time. Lastly, as the real sun moves equably through $STUVW$, from φ towards φ ; and the fictitious sun through $stuvw$, from r towards φ , the former comes later every day to the meridian than the latter, until they both arrive at the point φ , and then they make it noon at the same time with the clock.

537. We now proceed to explain the other cause of this difference, viz. the inequality of the sun's apparent motion, which is slowest in summer, when the sun is farthest from the earth, and swiftest in winter when he is nearest to it.

538. As the real sun moves unequally in the ecliptic, let us suppose a fictitious sun to move equably in a circle coincident with the plane of the ecliptic. Let $ABCD$ in plate V, fig. 2, be the ecliptic or orbit in which the real sun moves, and the dotted circles $abcd$ the imaginary orbit of the fictitious sun: each going round in a year according to the order of letters, or from west to east. Let $HIKL$ be the earth turning round its axis the same way every twenty-four hours; and suppose both suns to start from A and a , in a right line with the plane of the meridian EH , at the same moment: the real sun at A , being then at his greatest distance from the earth, at which time his motion is slowest; and the fictitious sun at a , whose motion is always equable, because his distance from the earth is supposed to be always the same. In the time that the meridian revolves from II to H again, according to the order of the letters $HIKL$, the real sun has moved from A to F ; and the fictitious with a quicker motion from a to f , through a large arc: therefore, the meridian EA will revolve sooner from II to h under the real sun at F , than from II to k under the fictitious sun at f ; and consequently it will then be noon by the sun-dial sooner than by the clock.

539. As the real sun moves from A towards C , the swiftness of his motion increases all the way to C , where it is at the quickest. But notwithstanding this, the fictitious sun gains so much upon the real, soon after his departing from A , that the increasing velocity of the real sun does not bring him up with the equally moving fictitious sun, till the former comes to C , and the latter to c , when each has gone half round its respective orbit; and then being in conjunction, the meridian EII , revolving to EK , comes to both suns at the same time, and therefore it is noon by them both at the same moment.

540. But the increased velocity of the real sun, now being at the quickest, carries him before the fictitious one; and therefore, the same meridian will come to the fictitious sun sooner than to the real: for whilst the fictitious sun moves from c to g , the real sun moves through a greater arc from C to G : consequently, the point K has its noon by the clock when it comes to k , but not its noon by the sun till it comes to l . And although the velocity of the real sun diminishes all the way from C to A , and the fictitious sun

Fig. 11.

by an equable motion is still coming nearer to the real sun, yet they are not in conjunction till the one comes to A and the other to *a*, and then it is noon by them both at the same moment.

541. Thus, it appears, that the solar noon is always later than noon by the clock, whilst the sun goes from C to A; sooner, whilst he goes from A to C; and at these two points the sun and clock being equal, it is noon by them both

at the same moment. Upon these principles tables for the equation of time are calculated, the one giving the difference between the sun's true and mean motion; the other the difference between the sun's longitude and right ascension; from which the arc is calculated by addition or subtraction. But the calculation cannot, from the precession of the equinoxes, be depended upon for a considerable length of time.

542. By means of the following Table, however, of the Equation of Time for 1824, and the subjoined auxiliary Table, the Equation of Time may be found for any subsequent year in the present century, with sufficient exactness for regulating clocks and watches for the practical purposes of civil life.

543 Equation of Time, when the Sun is on the Meridian of Greenwich, for every day in the year 1824.

Add the Seconds from this Table, when the Equation on the corresponding day is increasing.
 Subtract decreasing.

USE OF THE PRECEDING TABLES.

545. Take from the first table the equation of time for the given day in the year 1824, and the daily difference of the equation, with this difference, or the nearest second to it in the side column of the Auxiliary Table, and below the leap year preceding the given year, will be found a correction, which applied to the equation before taken from the first Table, will give the equation on the given day of the leap year preceding the given year.

546. Then take $\frac{1}{3}$, $\frac{1}{2}$, or $\frac{2}{3}$, of the daily difference of the equation of time, according as the given year is the 1st, 2d, or 3d after leap year, and add it to the previously found equation on the same day of the preceding leap year, when that equation is decreasing; but subtract it when increasing; and the sum or remainder will be the equation at noon, Greenwich time, of the given day.

547. If the day proposed is in leap year, the correction for that year in the Auxiliary Table, applied to the equation of time on the proposed day in 1824, will give the required equation.

Example.—Required the equation of time, Sept. 12, 1867, at noon, Greenwich time?

548. Equation, see the first table, 3 min. 53 sec. subtractive; daily difference 21 sec. nearly. In table 2, opposite 20 sec. and below 1864, stands 6 sec.; which, added to 3 min. 53 sec., gives 3 min. 59 sec. the equation of time on Sept. 12, 1864. Now, 1867 is the third year after leap year; therefore, take $\frac{2}{3}$ of 21 sec. or 15 sec. and as the declination is increasing, subtract it from 3 min. 59 sec.; and the remainder 3 min. 44 sec. is the required equation at Greenwich noon of the given day, at noon.

549. By means of the following tables and rules, the sun's declination also, at noon, Greenwich time, may be found for any day in the present century, to within a few seconds.

TABLE I.

550. *The Sun's Declination at Noon, Greenwich time, for every Day in the Year 1824.*

USE OF THE PRECEDING TABLES.

552. To find the sun's declination on any day. Take from table I. the declination for the noon of the corresponding day in the year 1824, and the daily change of the declination. Opposite that daily change, in table II. and below the leap-year preceding the given one, will be found the first correction of the declination.

553. Multiply the seconds in the daily changes of declination, by the period of four years in table II. and parts of a period from 1824, to the given year, and the product multiplied by .0308 will give the seconds, in the second correction of the declination.

554. Lastly, take $\frac{1}{3}$, $\frac{1}{2}$, or $\frac{2}{3}$, of the daily change of declination, according as the year is the first, second, or third after leap-year, and the result will be the third correction of the declination.

555. Subtract the first correction from the declination on the corresponding day of 1824, add the second correction, when the declination is increasing, and subtract it when decreasing; and apply the third in a manner contrary to the second, and the result will be the declination at noon, Greenwich time, of the proposed day.—

Note.—If the given year be leap-year, the third correction is nothing.

Example.—Required the sun's declination at noon, Greenwich time, Oct. 18, 1875?

556. By table I. the sun's declination on Oct. 18, 1824, is $9^{\circ} 42' 25''$ S., and daily change $21' 47''$, increasing. Now the leap-year preceding the given one, is 1872, below which, in table II. and opposite $22'$ (the nearest minute to the daily change) stands $7''$, the first correction. As the given year is the third after leap-year, and there are (see table II.) 12 periods of 4 years from 1824 to 1872, there are $12\frac{3}{4}$ periods from 1824 to 1875. Hence, $12\frac{3}{4} \times .0308 \times 1307'' (21' 47'') = 513'' = 8' 33''$, the second correction, addition, because the declination is increasing. As the given year is the third after leap-year, we have $\frac{2}{3}$ of $21' 47'' = 16' 19''$, the third correction, subtraction, because the second is addition. Hence, the declination at the proposed time, is $9^{\circ} 42' 25'' - 7'' + 8' 33'' - 16' 19'' = 9^{\circ} 34' 34''$.

557. As immediately connected with this subject, we add a table of the sun's right ascension for the year 1824, with a method of adapting it to any subsequent instant in the present century, with sufficient exactness for ordinary purposes.

558. Table of the Sun's Right Ascension, at Noon, Greenwich Time, for every Day in the Year 1824.

559. To find the sun's higher ascension at the noon of any day, Greenwich time, till the year 1900.

Take the right ascension for the corresponding day of the year 1824 from the above table, and multiply 7.3s. by the periods of four years, and parts of a period from 1824 till the given period, and the product will be the period in the first correction, always to be added. Take $\frac{1}{4}$, $\frac{1}{2}$, or $\frac{3}{4}$ of the daily change of right ascension, according as the given year is the first, second, or third after leap-year; for the second correction always to be subtracted. Apply these corrections to the right ascension taken for the corresponding day of 1824, and the result will be the right ascension at the Greenwich noon of the proposed day.

Note.—If the given year is a leap-year, the second correction is nothing.

EXAMPLE.

Required the sun's right ascension, May 4, 1853.

560. The sun's right ascension, May 4, 1824, is 2h. 45m. 49s. and daily increase 3m. 51s. Now there are $7\frac{1}{4}$ periods of four years from 1824 till 1853; when $7.3s. \times 7\frac{1}{4} = 53s.$ the first correction; and $\frac{1}{4}$ h. of 3m. 51s. in 58s., the second correction. Then 2h. 48m. 55d. $\times 53s.$

—58s. = 2h. 45m. 40s. the right ascension at the proposed time.

SECT. III.—OF CALCULATING THE DISTANCES, MAGNITUDES, &C. OF THE CELESTIAL BODIES.

561. One of the first objects of an observer is to ascertain the latitude of his place of observation. There are many methods by which this may be effected. If the declination δ of any celestial object be known, and its distance z from the zenith be observed, then the latitude l will be either $= \delta + z$, or $\delta - z$, according as δ and z are of the same or different denominations. But the latitude may be determined from altitudes of circumpolar stars, independently of any previous knowledge of the places of those stars, for it is always equal to half the sum of their greatest and least altitudes. The pole star is most conveniently situated for observations of this kind, and it is generally observed for that purpose.

562. Considerable attention has been paid to the simplification of the method by which the latitude may be found from altitudes of this star when it is out of the meridian. Mr. F. Bailey, the present learned president of the Astronomical Society of London, has given the following formula, in which ψ is the colatitude, p the star's

polar distance, and t its meridian distance, and z its observed zenith distance, $\psi = z - \frac{p^2}{2} m^2 t \cdot \cot.$

$z + p \cos. t + \frac{p^2}{3} s \sin^2 t \cos. t.$ This formula may be put under the form $\psi = z + (p + C) \cos. t - B \cot. z$; whence, the coefficients $p + C$ and B being computed and arranged in tables, ψ may easily be determined.

563. The latitude being determined, it becomes next of importance to determine the inclination of the plane of the earth's orbit to the plane of the equator, or the obliquity of the ecliptic. This is the difference between the sun's greatest altitude and the colatitude of the plan of observation. If the sun was in the solstice at the moment at which he was on the meridian, the difference between his meridian altitude and the colatitude, would be the obliquity. This, however, is unlikely to happen, and, on the ground of utility, not at all to be desired; as, from meridional observations made near the solstice, the obliquity may be determined with a degree of accuracy to which no single observation could justify us in pretending.

564. If w be the obliquity, d the sun's declination, and \odot his longitude, d' the greatest declination, and \odot' the corresponding longitude; then,

$$\sin. d = \sin. \odot \cdot \sin. w$$

$$\sin. d' = \sin. \odot' \cdot \sin. w$$

When $\sin. d' - \sin. d = \sin. w (\sin. 90^\circ - \sin. \odot)$
Or, if $w = 90^\circ - \odot'$ and $w (= d') = d + \delta$,
 $\sin. \frac{\delta}{2} \cos. (w - \frac{\delta}{2}) = \sin. w \cdot \sin^2 \frac{u}{2}.$ And ex-

panding and substituting for $m \frac{\delta}{2}$ and $\cos. \frac{\delta}{2}$ their approximate values in terms of δ , we obtain

$$\delta = \frac{\tan. w \cdot \sin. s' \cdot u^2}{2}$$

from which, with the greatest ease, the correction to the declination d deduced from the altitude may be obtained, and hence from a series of meridional altitudes, observed on each side of the solstice, the obliquity of the ecliptic may be obtained to a very great degree of nicety.

565. The obliquity of the ecliptic being obtained, the next step in this department of enquiry is to ascertain the place of the equinoctial point, or that point on the ecliptic in which it crosses the equator. Now the point in which a star is when his meridian altitude is equal to the colatitude, will be the equinoctial point. Let a = his meridian altitude less than the colatitude, a' = his meridian altitude greater than the colatitude, n = the days between the two observations, u = the days between a may be considered as varying uniformly, we have $\frac{a' - a}{n} = \frac{a' - a}{n}$ the time after the sun had the altitude a when he was on the equator, whence his place at the time on the position of the equinoctial point, with reference to the meridian of any known fixed star may be determined.

566. The distances of the heavenly bodies are obtained by finding the horizontal parallax of the body whose distance is desired to be known; and as the horizontal parallax is the sine of the

of the earth would appear provided we could see it from that body. In general the parallax of a planet is the difference between the real and apparent place of a planet; that is, between its place seen from some part of the surface, and from the centre of the earth; so that the parallax is the angle under which the semidiameter of the earth, terminated by the place of an observer, is seen at the planet; and to find this parallax many methods have been devised.

567. I. Let A D, plate V. fig. 3, be the earth, C its centre, P the planet; and let the planet's distance CP from the centre of the earth be given. Then ZAP is the complement of the apparent altitude, ZCP the complement of the true altitude. As the planet's distance from the centre of the earth CP: to the earth's radius AC:: so is the cosine of the apparent altitude, S.ZAP: to the sine of the parallax. For draw AF parallel to CP. The angle FAP is equal to the angle APC. But ZAF is equal to ZCP, the true zenith distance, and ZAP is the apparent zenith distance; and their difference FAP, or its equal APC, is the parallax. But in the triangle CAP, it is CP: S.CAP or ZAP:: CA: S.CPA, or PAF, the parallax.

568. II. If the distances of two planets or stars, having the same apparent altitude, be known, and the parallax of one of them, let P and G be the planets in the line APG; then APC is the parallax of P, and AGC the parallax of G. Therefore in the triangle CPC, we have CP, CG, and an angle opposite, suppose G, to find the other opposite angle. Therefore distance CP: distance CG:: S.CGP: S.CPG or CPA; that is, the sines of the parallaxes are reciprocally as the distances from the earth's centre.

569. III. Let S be the star or planet whose parallax is sought. See plate V. fig. 7. Observe it when it is in the same vertical circle with any two fixed stars, A, B. Observe again when the same two stars come into a position parallel to the horizon at a and b ; and let the planet be come to s . Then with an instrument measure the altitude of a or b , and likewise the altitude of s ; and the difference of these altitudes is the parallax. For the real place of the star S, is somewhere in the line AB, and therefore it is also somewhere in the line $a b$, and therefore its altitude is the same as that of a or b . Therefore the parallax is the difference of the altitudes of a and s , or of b and s .

570. IV. Let S be the star or planet; observe its distance from any fixed star B, which is in the same vertical circle ZSB; and measure the distance SB with an instrument. Then observe again when the same two stars have equal altitudes above the horizon at b and s , and then take the distance $b s$. This distance will be very near the true distance of the stars B and S; therefore the first distance BS subtracted from the latter distance $b s$, when B is below S, gives the parallax; or the latter distance subtracted from the former, when B is above S, gives the parallax.

571. V. The parallax may be found by observing the azimuth and altitude of the star or planet. Let HZO, plate V. fig. 4, be the meridian, EQ the equinoctial, HO the horizon, Z the zenith, P the pole, S the star, ZSB a vertical circle pass-

ing through it. Observe the altitude BS, and the azimuth BO, and mark the moment of time when these observations are made; then observe the moment of time that the star comes to the meridian, and you then have the distance of time from the observations. Convert this into degrees, allowing only 23h. 56m. to 360°, (which is the time of the earth's rotation to the same star), and you have the arch ED or angle EPA, supposing PAD an hour circle. Therefore in the spherical triangle ZPA, we have the angle ZPA, and angle PZA equal to BO, and the side ZP the co-latitude, to find the side ZA the complement of the altitude; this subtracted from ZS, known by observation, the remainder AS is the parallax.

572. VI. Another method is performed by a telescope, with cross hairs in the focus. Direct the telescope to the planet, and turn it round till its motion is along one of the cross hairs, which represents part of the planet's parallel circle; and the other hair perpendicular to it, will represent its hour circle. Observe the time when the planet comes to this hour circle, there fix the telescope, and then take its altitude; then observe the time when some fixed star, whose right ascension is known, comes to the same hour circle. The difference of time between the planet and star coming to this hour circle, turned into degrees (allowing 360° to 23h. 56m.), gives the difference of right ascensions of the planet and star; and so the apparent right ascension of the planet is known.

573. When the planet comes to the meridian, observe it with the telescope, and note the time; and when the star comes to the meridian, note the time of that: then the difference of the times reduced to degrees as before, gives the true difference of right ascensions, whence the true right ascension of the planet will be known. Therefore let HO, plate V. fig. 8, be the horizon, HZO the meridian, Z the zenith, P the pole, A the true place of the planet, S its apparent place, ZSB a vertical circle; then in the triangle ZPS, we have ZP, ZS, and angle ZPS to find the angle PZS. In the triangle ZPA, we have ZP, angles ZPA, PZA; to find ZA, which taken from ZS, gives AS the parallax.

574. If the planet have a proper motion of its own, its true place will be always changing; and therefore the change of place must be computed for the time of the observations. This is done by observing its place when in the meridian, twice; and thence the change of place is had for 24 hours: and therefore the place at the times of observations will be had by proportioning the motion according to the times. Here the angle ZPS should be about 90°, to have APS the greatest possible.

575. VII. The operation represented in plate

$$\text{Hence } \Lambda = \frac{MPn}{\sin. ZP \cdot \sin. ZPM \cdot \text{cosect } PM} = \frac{MPn \cos. \text{declin.}}{\cos. \text{lat.} \sin. \text{hour angle.}}$$

$$\text{Or, calling } MPm \epsilon, \Lambda = \frac{\epsilon \cos. \text{declin.}}{\cos. \text{lat.} \sin. \text{hour angle.}}$$

We should have a similar expression for it, if the object were observed on the other side of the meridian, and therefore

$$\Lambda = \frac{\epsilon \cos. \text{declin.}}{\cos. \text{lat.} \times (\sin. h + \sin. h')} = \frac{\epsilon \cos. \text{declin.}}{2 \cos. \text{lat.} \sin. \frac{h+h'}{2} \cos. \frac{h-h'}{2}}$$

V. fig. 5, requires two observers in different places of the earth, and can be applied to none of the planets but Mars in opposition to the sun, or to Venus on the sun's disk. It is best performed when the sun is about the equinox. Let PERQ be the earth, PR its axis, EQ the equinoctial, S the planet Mars in opposition to the sun, and if near the perihelion, it is better. Let two places FG, be taken, the one in north latitude, the other in south latitude, the further from the equinoctial the better; and nearly in the same meridian, or rather so placed, that the line FG, drawn from the one to the other, may be nearly perpendicular to the orbit of Mars. By this there is a greater base to work upon. Then let the two observers pitch upon some fixed star as A, which Mars comes very near at that time; and the nearer the better. Having two good instruments perfectly alike, furnished with micrometers, and being situated at F and G; let them observe for several nights successively about midnight, the places of Mars at B and C, as he passes by the star A; and take the distances AB and AC every night, during his transit by this star. These observations are to be continued till the distances begin to increase, and no longer; for then he is past the star.

576. From these observations, the nearest distance of Mars from the star A may be found, as observed from the places F and G; at least they may be found by interpolation. Let these nearest distances be AB and AC; then we have the difference BC, or the angle BSC or FSG. And from the situation of the places F and G, the length and position of FG will be known; and by these FS may be found. And lastly, the angle which the radius of the earth subtends at the distance FS, or the horizontal parallax of Mars will be known. If, instead of Mars in opposition, Venus be observed on the body of the sun; then her nearest distances from either limb of the sun must be taken, whose difference will give the angle at Venus, subtended by FG; the rest as before. Thus the parallax of Venus will be obtained. The parallax of Mars, when nearest the earth, has been found 25", 27", and 30" at different times.

577. Besides these methods of computing the parallax, there is another depending on observations made out of the meridian, which may be thus explained: let M, plate IV. fig. 5, be the true place, and m the apparent place of a planet, Z the zenith, and P the pole, then MPm will represent the apparent change in the right ascension of the planet arising from parallax. This change may be thus estimated: make Pn = PM, and join Mn, MPn = Mn cosect MP = Mm sin. ZMP cosect PM = A sin. ZM. sin. ZMP cosect PM (A representing the horizontal parallax) = A sin. ZP sin. ZPM cosect PM.

This method serves tolerably well to find the parallax of the moon; and it has been applied successfully to find the parallax of Mars; but it requires observations of much too great nicety to determine by it the parallaxes of the two planets. Those are chiefly deduced from the parallax of the sun, as determined by the transit of Venus.

578. In the above investigations, the earth has been considered as a spherical body; but in computing the parallax of the moon, from observations, the peculiarity of the form of the earth becomes very apparent; and it is a striking circumstance that from the eclipses of the moon, we shew in a general way that the earth is round, and from her parallaxes that it is not spherical.

579. A star or planet appears lower than it really is, by the quantity of the parallax, which is greater the lower the star is; and therefore the horizontal parallax is the greatest. The parallaxes of two planets are as the cosines of the apparent altitudes directly, and their distances from the earth's centre reciprocally. For when the distance is given, the parallax is as the sine of the zenith distance (by method 1), and if the apparent altitude be given, the parallax is reciprocally as the distance, (by method 2), and therefore is in a compound ratio, when neither is given. Here the parallax being very small, one may take the parallax itself for the sine of the parallax.

580. The parallax of a planet being known, its distance may be found. For this is only working backward, saying, as sine of the parallax, to the earth's radius; so S zenith distance to the planet's distance.

581. Having the parallax of any of the planets, the distances of all the planets from the sun may be known, in diameters of the earth, or any sort of measure. For the distances of the planets from the sun and from one another, are known in some assumed measure; and by the parallax of a planet, the true distance of the earth from it is known; and therefore all the other distances will be known by proportion.

582. The seventh of these methods has been practised in determining the parallax of Venus, from observations made at different parts of the earth, upon what is called her transit over the sun's disk, a phenomenon that rarely happens; but when it does happen, it affords the best, and indeed the only accurate method of determining that most important problem in astronomy, the sun's parallax, or the angle under which the earth's semi-diameter appears from the sun.

583. The first transit or passage of Venus over the sun's disk, that ever was observed, happened in 1639, but perhaps the only mortals who saw it were Mr. Horrox and his friend Mr. Crabtree. Two transits have happened since; the first in 1761, and the last in 1769. There will be no more before 1974, and the next to that will happen in 1996. The two last transits were carefully observed. From the first of these Mr. Short has computed the sun's parallax to be $8.69''$; and from the last the best astronomers have concluded it to be $8.67''$. This is an observation of the greatest consequence, because it is only by a knowledge of the sun's distance from the earth, in some known measure, that we can acquire a knowledge

of the true dimensions of the solar system. For an account of the principles of this method of finding the solar parallax, see VENUS, transit of.

584. As to the fixed stars, no method of ascertaining their distance has hitherto been found out. Those who have formed conjectures concerning them, have thought that they were at least 400,000 times farther from us than we are from the sun.

585. Dr. Herschel has proposed a method of ascertaining the parallax of the fixed stars, something similar, but more complete, than that mentioned by Galileo and others; for it is by the parallax of the fixed stars that we should be best able to determine their distance. The method pointed out by Galileo, and first attempted by Hooke, Flamsteed, Molineux, and Bradley, of taking the distances of stars from the zenith that pass very near it, has given us a much juster idea of the immense distance of the stars, and furnished us with an approximation to the knowledge of their parallax, that is much nearer the truth than we ever had before.

586. But Herschel mentions the insufficiency of their instruments, which were similar to the present zenith sectors, the method of zenith distances being liable to considerable errors on account of refraction, the change of position of the earth's axis arising from nutation, precession of the equinoxes, and other causes, and the aberration of light. The method of his own is by means of double stars; which is exempted from these errors, and of such a nature that the annual parallax, even if it should not exceed the tenth part of a second, may still become more visible, and be ascertained, at least to a much greater degree of approximation than it has ever been done.

587. This method is capable of every improvement which the telescope and mechanism of micrometers can furnish; but as it goes on presumptions which can hardly lead to any firm conviction, we are not likely to gain any farther knowledge, than that the stars are at too great distance to be subjected as yet to our calculations. He supposes that the stars are, one with another, about the size of the sun; and that the difference of their apparent magnitudes is owing to their apparent distances; both of which suppositions being only hypothetical, it is evident that the conclusions founded on them cannot be depended on with absolute certainty.

588. Considerable discussion has recently taken place between Mr. Pond, the present astronomer royal, and Dr. Brinkley, respecting the annual parallax of α Lyrae, which parallax Dr. B. conceives his instrument shews clearly to be about $1.12''$. Mr. Pond, asserts, that the Greenwich circle is a better instrument than the Dublin circle, and that observations made with it give no indications of parallax either in α Lyrae, or in any other fixed star. Dr. Brinkley, however, has endeavoured to shew that, if the place of the pole-star can be relied on, the Greenwich observations do indicate a parallax in α Lyrae very nearly equal to that shewn by his instrument; but Mr. Pond, in a recent communication to the astronomical society of London, states, that observations on the pole-star are on the whole more unsatisfactory than any other star. What

ASTRONOMY. NORTHERY HEMISPHERE.

J. Shury Sculp.

ASTRONOMY. SOUTHERN HEMISPHERE.

J. Shury Sculp.

seems to go far towards settling this delicate question is, that there are now two circles in constant use at Greenwich; and that they agree together in a manner that must be gratifying to their distinguished makers, Mr. Troughton and Mr. Thomas Jones; they bear steady and united testimony against the parallax of the fixed stars, and shew even in some instances a tendency to exhibit a deviation of an opposite character.

SECT. IV.—OF THE DIVISIONS OF THE STARRY HEAVENS.

589. The stars, from their apparently various magnitudes, have been distributed into several classes, or orders. Those which appear largest, are called stars of the first magnitude; the next to them in lustre, stars of the second magnitude; and so on to the sixth, which are the smallest that are visible to the bare eye. This distribution having been made long before the invention of telescopes, the stars which cannot be seen without the assistance of these instruments, are distinguished by the name of telescopic stars.

590. The ancients divided the starry sphere into particular constellations, or clusters of stars, according as they lay near one another, so as to occupy those spaces which the figures of different sorts of animals or things would take up, if they were there delineated. And those stars which could not be brought into any particular constellation, were called unformed stars.

591. By this division, the stars are so distinguished from one another, that any particular star may be readily found in the heavens, by means of a celestial globe; on which the constellations are so delineated, that the most remarkable stars are placed in such parts of the figures, as are most easily distinguished. See plates I, and II.

592. The number of the ancient constellations is forty-eight, and upon our present globes about seventy. On Senex's globes are inserted Bayer's letters; the first in the Greek alphabet being put to the largest star in each constellation, the second to the next, and so on; by which means every star is as easily found as if a name were given to it. Thus if the star γ in the constellation of the ram be mentioned, every astronomer knows as well what star is meant, as if it were pointed out to him in the heavens.

593. The starry heavens are also divided into three parts, viz. 1. The Zodiac, which extends quite round the heavens; is about 16° broad, so that it takes in the orbits of all the planets, as well as that of the moon; and along the middle of which is the ecliptic. 2. All that region of the heavens which is on the north side of the zodiac, containing twenty-one constellations; and, 3. That on the south side, containing fifteen.

594. The following tables exhibit the names of the ancient and modern constellations, and the number of stars observed in each of them by different astronomers :

SECT. V.—OF CALCULATING THE PERIODICAL TIMES, PLACES, &c. OF THE CELESTIAL BODIES; CONSTRUCTING ASTRONOMICAL TABLES, AND DELINEATING THE PHASES OF THE MOON.

598. This section, if treated fully, would comprehend almost the whole of practical astronomy,

a subject so extensive, that the whole space which we can devote to the subject of astronomy would not suffice to do it justice. We shall, however, we hope, give an abstract of the leading points in this department of the science, which may at once gratify the wishes of the amateur,

and stimulate the further enquiries of those who may be inclined to pursue the subject.

599. Indeed the elements of the chief bodies in our system have long been tabulated, and the mere practical astronomer may, without any knowledge of the causes of the planetary motions, compute from the tables where any planet in the system will be found at any given instant. The tables in the third volume of Vince's Astronomy are a treasure to the astronomer, though those of the moon have been superseded by the improved ones of Burkhart.

600. We have already shown how an observer who knows his own latitude may find the position of the ecliptic with respect to the equator, and that point of the heavens in which the celestial equator and the ecliptic intersect. We now proceed to the solution of Kepler's problem, or to the method of finding the place of a planet in an elliptical orbit.

601. Let APB, fig. 12, plate VI., be an ellipse, E the sun in the focus, round which the earth, P, or any other planet revolves. Let the planet's motion, and the time of its motion, be dated from the extremity of the major axis, A, called the aphelion or apside. Now we are supposed to have given the time of the planet's quitting it, to find the position of the point P in the ellipse, either by finding the value of the angle AEP, or by cutting off from the whole ellipse and area AEP, which is to the area of the whole ellipse as the time from A to P bears to the whole time of revolution. The line EP is called a radius vector.

602. Let a circle AMB be described on AB as its diameter, and suppose a point to describe this circle uniformly, and the whole of it in the same time as the planet describes the ellipse, let t denote the time elapsed during P's motion from A to P; then if $\frac{2 \cdot t \cdot A M B}{\text{periodic time}}$ M will be

the place of the point that moves uniformly, whilst P is that of the planets; the angle is called the mean anomaly, and AEP the true anomaly.

603. Hence, as the angle ACM can always be found when t is given, the solution of Kepler's problem is reduced to this, to find the true anomaly in terms of the mean.

604. The angle DCA, determined by producing the ordinate A²P to the ellipse is called the eccentric anomaly, which has been devised for the purpose of expediting the computation of the true anomaly. It holds a mean between the two other anomalies, and is a step in the computation from the one to the other.

605. We shall first deduce two equations, by which the eccentric anomaly is expressed, in terms of the true and mean anomalies respectively.

Let t = the time in describing AP, P = the periodic time in the ellipse $a = CA$, $ae = EC$, $\nu = \angle PEA$, $u = \angle DCA$, (whence $ET = EC \cdot \sin u$, ET being perpendicular to DT) $\tau \rho = PE$, $\pi = 3 \cdot 1415986$; then, by the law of the equable description of areas,

$$t = P \times \frac{\text{area } PEA}{\text{area of ellipse}} = P \times \frac{\text{area } DEA}{\text{area } \odot}$$

$$\begin{aligned} \text{(by conics)} &= \frac{P}{\pi a^2} \times (DEC + DCA) = \frac{P}{\pi a^2} \times \\ & \left(\frac{ET \cdot DC}{2} + \frac{AD \cdot DC}{2} \right) = \frac{Pa}{2 \pi a^2} \times (E C \sin u + \end{aligned}$$

$$D C \cdot u) = \frac{P}{2 \pi} \times (e \cdot \sin u + u) : \text{hence if we}$$

$$\text{put } \frac{P}{2 \pi} = \frac{1}{n} \text{ we have}$$

$n t = e \cdot \sin u \times u$, an equation connecting the mean anomaly $n t$ with the eccentric u .

606. To find the equation between the true and eccentric anomaly we must investigate and equate two values of ρ . Now the value of ρ in terms of the true anomaly is by conics =

$$\frac{a \cdot 1 - e^2}{1 - e \cdot \cos u}$$

and in terms of u the eccentric anomaly $\rho = a \frac{1 + e \cdot \cos u}{1 - e^2}$

$$\begin{aligned} \text{In } \rho^2 &= EN^2 \times PN^2 = EN^2 + DN^2 \frac{1 - e^2}{1 - e^2} \\ &= a^2 + a \cdot \cos u \cdot a^2 + a^2 \sin^2 u \frac{1 - e^2}{1 - e^2} = a^2 + 2 e \\ & \cos u + \cos^2 u + a^2 \frac{1 - e^2}{1 - e^2} \sin^2 u = a^2 + 2 e \\ & \cos u - e^2 \cos^2 u \text{ when } \rho = a \frac{1 + e \cdot \cos u}{1 - e^2} \end{aligned}$$

By equating these two values of ρ we have, $1 - e^2 = \cos u \frac{1 + e \cdot \cos u}{1 + e \cdot \cos u}$; whence $\cos u = \frac{e + \cos u}{1 + e \cdot \cos u}$, an expression which may readily

be transformed into $1 \tan \frac{u}{2} \sqrt{\frac{1 - e}{1 + e}} \tan \frac{u}{2}$

The difference between the mean and true anomalies is called the Equation of the Centre; which has its greatest value when P moves with its mean angular velocity, as may be thus made evident. If we conceive a body to move uniformly in a circle round E, as a centre, with the mean angular velocity of P round E, revolving round the circle in the same time that P revolves round the ellipse. If they both depart from P together, then P at the first moving with its least angular velocity, will describe round E a less angle than the fictitious body does, which body will therefore advance before P, till the angular velocity of P becomes equal to that of the body, at which time their angular distance will be the greatest, and P will immediately afterwards begin to gain upon the body.

608. To determine the ellipse in which the equation of the centre is the greatest, conceive a circle to be described round E as a centre, setting the ellipse on some point P, and the line EA somewhere between E and A. Then, if the angular velocities be inversely as the squares of the distances from E, the angular velocity in the ellipse from A to P, will in every intermediate point be less than the angular velocity of the body in the circle, in all the points between EA and P. But if the areas described by the body in the ellipse, and the body in the circles, be respectively equal, the angular velocities are inversely as the squares of the distances.

609. If then the incremental areas be equal, the whole areas are equal, since by condition, the lines of revolution are equal. Let therefore X be put for the value of EP, $2a =$ the major axis, and $ae =$ the eccentricity of the ellipse, then by equating the expression for the elliptic area,

and that of the circle we obtain

$$r = a \times \sqrt{1 - e^2}^{\frac{1}{2}} = a \times \left(1 - \frac{e^2}{4} - \frac{3}{32} e^4 \right)$$

nearly.

609* From the above value of the radius vector when the equation of the centre is the greatest, the corresponding, true, and eccentric anomalies may be computed by the general equations for those purposes given above.

$$\text{Viz. } \rho = \frac{a \cdot 1 - e^2}{1 - e \cos u} \rho = a \cdot 1 + e \cdot \cos u;$$

and hence, too, the mean anomaly nt is determined from $nt = u + e \cdot \sin u$, and finally there results the greatest equation of the centre $= + v - nt$.

We proceed now to the principles of the method by which the place and motion of the aphelia are determined.

610. It is evident that the sun being in perigee at the least distance and in apogee at his greatest, if we could measure his diameter with sufficient nicety, so as to determine when it is greatest or least, the corresponding places of the sun would be those of the perigee and the apogee respectively; or if, by observing the sun's place from day to day, we could ascertain the times when his angular motion was the greatest or least, his places at the corresponding time would be those of the required points. And if, at a period considerably distant, like observations were repeated, a comparison of the results would shew whether the place of the apogee was stationary or not.

611. Now by the observations of various astronomers, it has been found that the apogee of the earth's orbit is progressive, as may be seen from the following statement:

Astronomer.	Year.	Longitude of Apogee.
Cochin King . . .	1279	3s. 0 ^o 8' 0 ^o
Waltherus . . .	1496	3 3 57 57
La Hire . . .	1684	3 7 28 0
Flamsteed . . .	1690	3 7 35 0

The mean result of these observations gives about 1' 34" for the annual progressive motion of the apogee of the earth's orbit.

612. The following, however, is a more accurate method of determining the progression of the apogee. Let SEr (fig. 13. Plate VI.) be a right line, and draw TEt , making with AB , the major axis, an angle $TEA = SEA$; now the time through $rBtS$ is less than the time through the remaining arc SAt ; for the equal and similar areas SEt , TEr , are described in equal times, but the area rEt , is less than SEt , and it will therefore be described in less time; whence $rEt + SEt$, which is equal to $SEr + tS$, is described in less time than $SET + TEr$, which compose the area $SErTS$. This property belongs to every line drawn through E , except AB , the major axis, or the line which joins the aphelion and perihelion of the orbits. Hence, if on comparing two observations of the sun in opposite longitudes, as at S and r , it appears that the time elapsed is not half a year, we may be sure that the sun has not been observed in apogee or perigee. In practice, however, the interval will not differ much from half a year, and the true position of the apogee may be determined in the following manner:

613. The time from r to $S =$ the time from r to $B +$ the time from B to $A -$ the time from S to A ; or, time from B to $A -$ time from r to $S =$ time from S to $A -$ time from r to B . Now the first of these differences is known, being the difference between half an anomalistic year (the time from the sun's leaving the apogee till his return to it) and the observed interval; and the second term of the second difference may be expressed by means of the first. For let the first term $= t$, then the time from r to $B = t \cdot \frac{\text{area } rEB}{\text{area } SEA} = t \cdot \frac{rB \times EB}{SA \times EA}$ (r and S being supposed near the apsides)

$$= t \cdot \frac{rB}{EB} \times \frac{EA}{SA} \times \frac{EB^2}{EA^2} = t \times \frac{EB^2}{EA^2}$$

$$= t \times \frac{\text{angular velocity at } A}{\text{angular velocity at } B} \text{ For } \frac{rB}{EB} = \frac{SA}{AE}$$

each representing the incremental angle rEB .
614. Now the angular velocities at A and B , or the increments of the sun's longitude, being known from observation, and the time from r to B being expressed in terms of those velocities and of t , the quantity t may be readily determined; whence the exact time when the sun is at A ; and his longitude, computed for that time, is the longitude of the apogee.

EXAMPLE.

1743. Dec. 30. 0h. 3m. 7s.	☉'s long. 9s 8° 29' 12.5"
1744. Jun. 30. 0h. 3m. 0s.	3 8 51 1.5
Difference	6 0 21 4.9

Therefore after the second observation, June 30th, the sun was past S . In order to find when t e was at S , that is, when the difference of the longitude was six signs (or supposing the perigee to have progressed through 31") when the difference of the longitudes was 6 s 0° 0' 31", we must find the time of describing 21' 49" — 31", or 21' 18". This is easily effected by this proportion, as the sun's daily motion on June 30th (57' 12"): 24 hours : 21' 18"; 8h. 56m. 13s., which taken from June 30th, 0h. 3m., leaves June 29th 15h. 6m. 47s. for the time when the difference of the sun's longitudes under the given circumstances was 180° 0' 31".

615. The interval between this last time and Dec. 30th, 0h. 3m. 7s. the time of the past observation, is 182d. 15h. 3m. 40s., nearly the time from r to S : but this time is less than half an anomalistic year, which is 182d. 15h. 7m. 1 s., as has been found by repeated observations, and as we have seen above: $t -$ time from r to $B = 3m. 21s.$; and time from r to $B = t \cdot \frac{57' 12''}{61' 12''}$; whence, by substitution and reduction, we have $t = 47m. 54s.$ This added to June 29th, 15h. 6m. 47s., when the sun was at S , gives June 29th 15h. 6m. 47s. for the time when he was in apogee.

616. The sun's longitude at that time must be less than his longitude on June 30th, 0h. 3m. by the difference due on the difference of the times, which is 8h. 8m. 19s. This quantity is easily found by proportion to be 19°. 21", and

hence the longitude of the apogee is $98^{\circ} . 31' . 40.5''$, or $8^{\circ} 31' 40.5''$ past the summer solstice.

617. From the longitude at any given time and the annual progression, the position of the apogee and of the axis of the solar ellipse may be found by proportion for any other time. If it were required, for example, to find when the axis of the solar ellipse was perpendicular to the line of the equinoxes, or when the longitude of the perigee was 270° . Now its longitude in 1750 was $9^{\circ} 8' 37'' 28''$, hence, taking the annual progression at $62^{\circ} . \frac{8^{\circ} 37' 28''}{.62^{\circ}} =$ about 500

years, as the major axis was perpendicular to the line of the equinoxes in 1250. It is remarkable, that the period in which the major axis coincided with the time of the equinoxes, is at the time which astronomers consider to be that of the beginning of the earth.

618. Our next object is to explain those observations made at the earth, and reduced to what they would have been if the observer had been at the sun; as the methods of extricating from the geocentric observations of a planet's place, the elements of the orbit which it describes round the sun.

619. The observations made on the earth are, generally speaking, for right ascensions by the transit instruments, and polar distances by the quadrant or axle. The latitudes and longitudes are not observed, but computed from the right ascensions and declinations. Let A, fig. 15. plate VI., represent the first point of Aries, AC a portion of the ecliptic, AB a portion of the equator, S a star, SB its declination, and SC its latitude; then AB will be its right ascension and AC its longitude round BAC, the obliquity of the ecliptic. Now the method of finding BAC has already been shown; BS is determined by the circle or quadrant, and AB by the time shown by the sidereal clock when the sun is on the meridian. Hence AC, CS, and the angle BAC, are given to find AB and BS. Now $\cos. AS = \cos. AC . \cos. CS$; $\cos. SAC = \cos. CS . \sin. AC, SAB = SAC = BAC$; $\tan. AB = \cos. SAB . \tan. AS$ and $\sin. BS = \sin. AS . \sin. BAS$. Hence the geocentric latitudes and longitudes may be always determined.

620. If $a =$ the right ascension, $d =$ the declination, $l =$ the latitude, $\lambda =$ the longitude, and $o =$ the obliquity of the ecliptic, then l and λ may be determined from the following equations:

$$\tan. \lambda = \sin. o . \tan. d . \sec. a + \tan. a . \cos. o$$

$$\sin. l = \sin. d . \cos. a - \sin. a . \cos. d . \sin. o$$

621. By either of these methods the geocentric latitude and longitude may be determined. Among the resulting values of the latitude, some will be either nothing or very small. If the geocentric latitude is nothing, the heliocentric latitude is also nothing, or the planet is in the plane of the earth's orbit, or in that point of its own orbit which is called its node; the node being the intersection of the orbit of a planet with the plane of the ecliptic. It is not likely, however, that the planet will be observed exactly in the node; but if by one observation its latitude is found to be a south, and

by another at an interval of time t , to be a' north.

the $\frac{a t}{a + a'}$ is the interval, which added to the

time when the planet had the latitude, a will give the instant at which it was in its node.

622. As we can thus find the time of a planet's entering its node, we can determine the time of its passage from the descending to the ascending node, and also the time between two successive returns to the same node; and if the place of the nodes and the dimensions and line of the orbit remain unchanged, the latter interval must be the periodic time of the planet; and if the former interval were half the latter, it would prove either that the orbit of the planet was circular, or, if elliptical, that its major axis coincided with the positions of the nodes.

623. Now let NP, fig. 14, plate VI. be part of the orbit of a superior planet, N π C a portion of the ecliptic, E the earth, S the sun; and let P π be an arc of a great circle from P perpendicular to the ecliptic. A spectator at E, sees P π under the angle P E π , which is therefore the geocentric latitude; and a spectator, as S, would see P π under the angle P S π , which is therefore the heliocentric latitude. If γ be the first point of Aries, then as the diameter of the earth's orbit subtends no sensible angle at the fixed stars, a line drawn from E to γ may be considered as parallel to a line drawn from S to γ . Hence

the geocentric longitude of P (L) is $\angle \pi E \gamma$
 the heliocentric longitude of P (P) is $\angle \pi S \gamma$
 the longitude of the sun, (\odot) is $\angle S E \gamma$,
 and consequently,

$$L = \odot + \angle S E \pi = \odot + E,$$

E representing the angle S E π , called the angle of elongation.

624. The angle E S π , is called the angle of commutation, (C) the angle S π E, or rather the angle S P E, under which the earth's radius appears from the planet, is called the annual parallax.

625. To proceed. $\gamma S \pi, (P) = \angle S E \gamma + 180^{\circ} - E S \pi = \odot + 180^{\circ} - C$, whence P may be determined, if C be previously known. But S E is known from the solar theory, and S E π , or $E = L - \odot$ is known, since L can be computed as we have shown above from the observed right ascension and declination, and \odot is known from the solar theory; therefore to find the angle E S π , and all the other parts of the triangle, it is only necessary to know S π , which is called the curvate distance.

626. Now S $\pi = S P \cos. \angle P S \pi = \gamma . \cos. H$; whence to find S π we must know the values of γ and H. Let I = P N π , represent the inclination of the planet's orbit, to the plane of the ecliptic. Then by spherics, $\tan. H = \cos. N \pi . \tan. I$, whence to find H we must previously know I and N π , the distance of the reduced place of the planet from the node of its orbit, which distance is evidently equal to the longitude of the planet, minus the longitude of the node.

627. If the eccentricity of the orbit be small, S P, or r , may be determined by Kepler's law, but it is the mean distance which is determined

by that law; and therefore except P move in a circle, S P so determined will not be quite correct. And in fact there is no direct and general method of determining S P. Astronomers therefore select those positions of a planet in which its heliocentric longitude is exactly known. Now when the inferior planets are in conjunction, their longitudes are exactly known, as when they are in superior conjunction their longitudes are equal to \odot , and in inferior equal to $180^\circ + \odot$.

628. In such positions then the heliocentric longitude is obtained without any knowledge of S P, and without trigonometrical computation. The geocentric longitude may be computed from the right ascension and declination by the formulæ already given.

629. If we conceive N π C to represent the earth's orbit, and e E that of an inferior planet, then E π S is called the planet's angle of elongation, and π E S its annual parallax, when π E is a tangent to E e.

To find the periodic time, mean motion, and distance of a planet.

630. From the observed right ascensions and declinations compute its geocentric latitude; and find when it is equal to nothing. The planet is then in its node. Find in the same way at some subsequent period when it returns to the same node, and thence the periodic time may be determined.

631. This method of finding the periodic time serves also to show whether the orbit is eccentric, and the degree of the eccentricity; as will appear from the following detail given by Delambre, for finding the periodic time of Mars:—July 23d, 1807. ζ in his descending node (ζ) and his southern latitude increased till Dec. 16th. If the latter time be assumed as that when his latitude was greatest, and the interval (145 days) of his passage from the node to that position, be taken as one-fourth of his periodic time, the period will then be 560 days.

632. But on May 21st, 1808, ζ in his ascending node (Ω) and the interval in his passage from ζ to Ω was 302 days. If that interval were half the period, the period would be 604 days.

633. Again on March 7th, 1809, the north latitude of Mars was $2^\circ 49'$; and in June 8th, it was (0) , when Mars had returned to the node in which he was on July 23d, 1807, in 687 days, which must be very nearly the period of his revolution.

634. Now from this detail, and what we have done before, we may infer that the orbit of Mars is not circular, and that the major axis is neither perpendicular to, nor coincident with, the line of the node.

635. But we may draw farther inferences. The time from ζ to Ω being less than the other half of the period by 83 days; if (plate VI. fig. 13) N n represent the line of the nodes, we have $\frac{N A n - N B n}{N A n} = \frac{83}{385}$ since the areas are proportional to the times. Now when N n is perpendicular to A B, the difference between N A n and N B n is a maximum. In such a position $\frac{A E n - N E B}{A E n}$ would be nearly $\frac{41}{193}$ or the

time from B to N would be nearly 152 days and from N to A 193 days.

636. But the period being nearly 687 days in which the planet describes 360° the time of describing 90° would be nearly 171 days, supposing the planet to depart from B, and to move with its mean motion; but as we have seen, the planet was in N nineteen days previously, in which time its mean motion is equal to nearly 10° . When the real planet therefore was at N, the fictitious body moving with the planet's mean motion would be nearly 10° behind. Now this difference is what has been denominated the equation of the centre, which at N is nearly at its greatest value. Hence the greatest equation of the centre in Mars cannot be less than 10° . The same process for finding the periodic time, and like inferences respecting the eccentricity are applicable to Jupiter and Saturn. But the Georgian planet has not completed more than half a revolution since it was first discovered, and yet we have the elements of its orbit to a very considerable degree of exactness. The following method of determination by La Lande (one indeed of trial and conjecture, but which after a few times is sure of succeeding) will be easily understood.

637. Resuming the notation already employed; the angle of elongation (E) = $L - \odot$, L being the geocentric longitude, and E π S, the angle of parallax (π) is the difference of the heliocentric and geocentric longitudes, and therefore equal to $P - L$. Now $E = L - \odot$ is known, and π is known from the expression $\sin. \pi = \sin. E, \frac{S E}{S \pi}$

if we can find S π . If we assume a value (r) for S π (S π and S P being nearly equal) we shall from the above equation have a corresponding value of π , and thence of P: let this value be represented by P'. Make another computation with π and a second and third geocentric longitude, and let the resulting heliocentric longitudes be P'' and P'''. Then we have P' - P, P''' - P', and P'' - P', and from the three times of observation, t; t'' and t''' we have t'' - t', t''' - t'' and t''' - t'.

Hence P''' - P': t''' - t' :: 360° : planet's period,
Or P'' - P': t'' - t' :: 360° : planet's period,
As P' - P': t' - t' :: 360° : planet's period.

638. By any of these three proportions may the period be computed; but r is assumed as the mean distance, and if $1 =$ the earth's mean distance, and p its periodic time; the periodic time of the planet will be represented by $p r \frac{1}{2}$; and if this result agree with the former one, it will be a proof that r has been rightly assumed; and the disagreement by its nature and magnitude will point out the manner and extent of correcting the first assumption for γ .

639. La Lande computed from three geocentric observations of the planet made on April 25th, July 31st, and Dec. 12th, 1781, and he found from the above formulæ, the periodic time. The two values disagreeing he amended his first assumption, guided partly by conjecture and partly by his first trial, till a value of r was obtained which agreed with all the observations.

640. The distance of an inferior planet may also be determined from observations on its dis-

tance from the sun when stationary, or from what has been called its greatest elongation. Let E and E' be the two of the greatest elongations, one when the planet is in aphelion and the other in perihelion, e the eccentricity of the orbit, R and R' the distances of the earth from the sun, and r the planet's mean distance; then $e = \frac{R \sin E - R' \sin E'}{2r}$ an equation which deter-

mines the relation between the eccentricity and mean distance.

641. We proceed now to the method of determining the place of the node of a planet's orbit, and the inclination of its orbit to the plane of the ecliptic. In fig. 16, plate VI. let Nn , represent the nodes. Now from the observed right ascension and declination we can in an hour even compute the planet's geocentric latitude, and when this is equal to 0, the planet is in its node. Let E, E' be the two positions of the planet when, as viewed from the earth, it is respectively at n and N . Then $SEn =$ geocentric longitude of planet at $n - \odot$ and $SE'N = \odot' -$ geocentric longitude of planet at N . Now we already know how to compute SN or Sn , and hence in the triangles $SEn, SEN, SE'N$, we can compute the angles nSE, SnE , and NSE', SNE' ; and thence heliocentric lon. of $n = 180 + \odot - \angle nSE$ and heliocentric lon. of $N = \odot' - 180 + \angle NSE', \odot$ and \odot' representing the sun's longitudes at the two times of observation; and the angle ESE' is proportional to the earth's motion during the planet's passage from n to N .

642. It is evident that the determination of the place of the node is the more difficult, the less is the inclination of the planet's orbit; and it is difficult on this account to determine the nodes of the orbits of Jupiter and the Georgian planets.

643. The longitude of the node being found, the inclination of the orbit may be thus determined: Compute the day on which the sun's longitude will be the same, or nearly the same as the longitude of the node, the earth will then be nearly in the line of the nodes Nn , at some point e , fig. 16, plate VI. On that day observe the planet's right ascension and declination, and thence deduce the geocentric latitude (G). Then

$$t \cdot v = e t \tan. G = S t \frac{\sin. t S e}{\sin. S e p} \tan. G = \frac{\sin. N t}{\sin. E}$$

$\tan. G$; but $\sin. N t = \cot. t N p \cdot t p$; or $\tan. I \sin. N t = t p$ (I denoting the inclination); whence

$$\tan. I = \frac{\tan. G}{\sin. E}. \text{ A like diagram and a similar}$$

process will apply to a superior planet. The inclination may also be determined from observing the planet at conjunction when its latitude is considerable. If $r =$ the planet's distance from the sun reduced to the ecliptic, I the inclination, and G , as above, the geocentric latitude. Then it may be easily shown, that :

$$\tan. I = \left(1 - r + \frac{r}{2} \tan. ^2 I \right) \frac{\tan. G}{\sin. (\odot - \oslash)}$$

$$\text{Hence } \overline{V' - V - M' - M} (= a) = 2 e. \left\{ \sin. \overline{V' - \phi} - \sin. \overline{V - \phi} \right\}$$

$$\text{And } \overline{V'' - V' - M'' - M'} (= b) = 2 e. \left\{ \sin. \overline{V'' - \phi} - \sin. \overline{V' - \phi} \right\}$$

an equation from which I may be obtained, either by approximation, or the solution of a quadratic equation.

644. The next step in the investigation is the determination of the form of the planetary orbits. For the sake of simplifying the problem, in the first instance, we shall suppose that the planet's orbit lies in the plane of the ecliptic. Since the mean motion is known from the periodic time, and by observing in opposition or conjunction the planet's true longitude we can at any instant determine its mean longitude. Then if the elapsed time were the interval between two conjunctions, and the orbit were circular, the computed mean longitude would agree with the last observed longitude; and a difference would be an indication of the orbit's eccentricity; which difference must depend both on the eccentricity and the place of the aphelion.

645. To apply these considerations to the subject in hand, let N (fig. 14, plate VI.) be the node of the orbit. Then as its longitude may be considered (from what has preceded) as known, and the longitude of a planet when in conjunction with the sun is known, being equal to $180^\circ + \odot$, if we deduct the longitude of the planet from the longitude of the node, there remains $N \pi$. Now as the elliptical motion takes place in the orbit NP it is requisite to know $N P'$, and other like distances of the planet from its node. But $N \pi$ being known, and the angle $P N \pi$; the distance $N P$ may be computed. For let $P' N = \cos. N. \cos. N \pi$.

646. If we set off on the orbit of the planet an arc (A) $= N r$, the longitude of the node, we shall have $A + N P$ which is called the longitude of the planet on its orbit; and we can have as many such longitudes as there are observations in conjunction or opposition.

647. Three observations are sufficient to determine the two elements of the eccentricity, and the place of the aphelion; for if we have three longitudes (V', V'', V''') we have two independent differences of longitude, and as soon as the planet's period is known, we can compute two portions of its mean motion corresponding to the two corresponding noted intervals of time; and the two real differences of longitude compared according to the elliptic theory, with the corresponding portions of mean motion, will give us two equations for determining the eccentricity and place of the aphelion.

648. Let e be the eccentricity (supposed to be very small) ϕ the longitude of the perihelion, the place of which suppose to be at some point between N and P , and let M, M', M'' , be the mean anomalies reckoned from the perihelion. Then we have

$$V - \phi = M + 2 e. \sin. \overline{V - \phi}$$

$$V' - \phi = M' + 2 e. \sin. \overline{V' - \phi}$$

$$V'' - \phi = M'' + 2 e. \sin. \overline{V'' - \phi}$$

Now as V, V', V'' are known, and $\overline{M''-M}$ $\overline{M'-M}$ are known from the period of the planet and the elapsed time; for if t be the interval between the observations of V and V' ; we have Planet's period : $360^\circ :: t : M' - M = \frac{t \cdot 360^\circ}{\text{period}}$.

Hence since a and b are known, we have two equations for determining e and ϕ . If the first

$$e = \frac{a \cdot \sin. 1''}{2[\sin. \overline{V''-\phi} - \sin. \overline{V-\phi}]} = \frac{a \cdot \sin. 1''}{4 \cdot \sin. \frac{V''-V}{2} \cdot \cos. \left(\frac{V'+V}{2} - \phi \right)}$$

649. Then e and ϕ , and the major axis being determined, we can compute the radius sector γ

from this expression, $r = \frac{a \cdot 1 - e^2}{1 + e \cdot \cos. \overline{V-\phi}}$:

and since the place of the node, and the inclination of the orbit are determined, we can compute the curtale distance $S \pi$, on the supposition that $S P$, from which it is deduced, is the radius vector of an elliptical orbit. If, therefore, in any of the processes for determining the elements of the planet's orbit, the curtale distance $S \pi$ has been supposed derived from $S P$, considered as a mean distance, we may now, with a more correct value of $S \pi$, repeat the operations and correct the results.

650. We shall now direct our attention to the method of finding the synodical revolutions of the planets, and of computing their returns to the same point of their orbits.

651. The time between conjunction and conjunction, or between opposition and opposition, is called a synodical period. Let us suppose that at a given instant the sun, Mercury, and the earth, are in the same right line; then, after any elapsed time (a day for example), Mercury will have described an angle m , and the earth an angle M , round the sun, therefore at the end of a day the separation of Mercury from the earth, as seen from the sun, will be $m - M$, and at the end of s days $s \cdot m - M$; and when $s \cdot m - M = 360^\circ$, the sun, Mercury, and the earth, will be again in the same right line, and in that case

$$s = \frac{360^\circ}{m - M}$$

where s denotes a synodical period and m, M the mean motions of Mercury and the earth for any equal intervals of time.

653. Let P and p denote the sidereal periods of the earth and the planet; then, since $1 \text{ d.} : M^\circ :: P : 360^\circ$ and $1 \text{ d.} : m^\circ :: p : 360^\circ$, we have $M = \frac{360}{P}$ and $m = \frac{360}{p}$; which substituted for m and M in the preceding equation, gives $s = \frac{P \cdot p}{P - p}$. Or if r represents the earth's mean distance, and r' that of the planet; we have $P : p :: 1 : r'^2$; or $\frac{P}{p} = r'^{-2}$ whence $s = \frac{P}{r'^{-2} - 1}$.

We have here three expressions, from any of which s may be computed.

654. For instance, in the case of Mercury, $p = 87 \text{ d. } 269$, and P being $365 \cdot 269$, we have s , the synodical period of Mercury $= \frac{365 \cdot 256 \times 87 \cdot 969}{277 \cdot 287} =$

115d. 21h. nearly.

of these equations be divided by the second we have

$$\frac{a \cdot \sin. \overline{V-\phi} - \sin. \overline{V'-\phi}}{b \cdot \sin. \overline{V''-\phi} - \sin. \overline{V'-\phi}} \text{ from whence, by reduction we obtain } \tan. \phi = \frac{a \cdot \sin. \overline{V''-\phi} - \sin. \overline{V'-\phi} - b \cdot \sin. \overline{V'-\phi} - \sin. \overline{V-\phi}}{a \cdot \cos. \overline{V''-\phi} - \cos. \overline{V'-\phi} - b \cdot \cos. \overline{V'-\phi} - \cos. \overline{V-\phi}}$$

Hence, ϕ being determined, we have

In the case of the moon, $m = 13^\circ \cdot 1763$, and M , the earth's daily mean motion $= 59' \cdot 8'' \cdot 3$; whence $s = \frac{360^\circ}{m - M} = 29 \text{ d. } 12 \text{ h. nearly}$

655. Since $s = \frac{P \cdot p}{P - p}$, $p = \frac{s \cdot P}{s + P}$; there-

fore from the known periodic time of the earth, and the observed synodic period of a planet, we can determine p , the periodic time of the planet. But to insure accuracy in the determination, the return of the planet to a conjunction nearly in the same part of its orbit, at which a previous one was observed, ought to be noted, and the interim divided by the number of synodical revolutions will give the mean synodic period. For under these circumstances there will be nearly a mutual compensation of the inequalities arising from the elliptic form of the planet's orbit.

656. Another reason for attending to this caution, is that on such conjunction depend the transits of Venus and Mercury, over the sun's disk. For it is evident that Venus to be seen on the sun's disk, must not only be in conjunction, but near the node of her orbit: at the next conjunction, after one synodical revolution, she cannot be near her node, and can only be again near when she returns to the same part of her orbit, as at the first time of observation.

657. The preceding formulæ for the synodic periods afford us the means of knowing these particular conjunctions.—

The time s of a synodic period is $= \frac{P \cdot p}{P - p}$,

therefore at $\frac{n \times P \cdot p}{P - p}$, the planet will still be in

conjunction, n representing any whole number. It will therefore be for the first time in conjunction, and the earth and planet will also be in

the same part of their orbits, when $\frac{n \cdot P \cdot p}{P - p} =$

P , or when $n = \frac{P - p}{p}$. Hence the required

conjunction can only take place when $\frac{P - p}{p}$, or

some of its multiples is a whole number, say

when, $\frac{m \cdot P - p}{p} = n$, or when $\frac{m}{n} = \frac{p}{P - p}$;

whence we have simply to find two integers, m and n , such that $\frac{m}{n} = \frac{p}{P - p}$.

658. Now the tropical revolution of Mercury is $87 \cdot 968$ days, hence $\frac{m}{n} = \frac{87 \cdot 968}{365 \cdot 256 - 87 \cdot 968}$

$\frac{87-968}{277-288}$, consequently in 87,988 periods of the earth, there will be 277288 synodical revolutions of Mercury, which will then be observed again in conjunction, and in the same part of its orbit. This result however, from the length of the period, is of no practical use; we must, therefore by means of continued fractions (see ALGEBRA) endeavour to find fractions in smaller terms, having nearly the same value as $\frac{87968}{277288}$.

659. Making the computation we find the following series of fractions continually approximating to this value.

$$\frac{1}{3}, \frac{6}{19}, \frac{7}{22}, \frac{13}{41}, \frac{33}{104}, \frac{46}{145}, \&c. \text{ in}$$

which the denominators denote the number of synodical revolutions, corresponding to the number of years expressed by the numerator. Take as an example the fourth fraction, in thirteen years, one 474·8328 days, and forty-one synodical periods, 475·0875 days, differing by only about six hours. If the sixth fraction be taken the difference will be little more than two hours.

660. In a similar way we may compute a series of fractions which will indicate the periods when transits of Venus may be expected. Thus, as Venus's period (p) = 224 d. 7008240, and the earth's (P) = 365d. 256385, the synodical

$$\text{period of Venus (s)} \frac{Pp}{P-p} = 583\cdot92 \text{ d. nearly;}$$

and consequently in one synodical period the earth describes $575^{\circ}\cdot51$ nearly; as in n synodical periods, $n \cdot 575^{\circ}\cdot51$; and when this first becomes a multiple of 360° , the earth and Venus will be first in conjunction, in the line from which they originally departed. If, therefore, Venus were so near the node in this original position that a transit took place, a transit will take place when

$$\text{(as before)} \frac{m}{n} = \frac{57551}{36000} \text{ Whence, by continued}$$

fractions, we obtain $\frac{1}{1}, \frac{2}{1}, \frac{3}{2}, \frac{8}{5}, \frac{222}{142}, \frac{235}{143},$

&c. a series of approximating value to $\frac{57551}{36000}$, from

which we are able to tell after what number of synodic periods Venus and the earth will be nearly in the same parts of their orbits.

661. Thus, taking the fifth fraction, we infer that after 142 synodic periods, 227 circumferences nearly, will be described; or 142 synodic periods are nearly equal to 227 years; and on trial we find $575^{\circ}\cdot51 \times 142 = 360^{\circ} \times 227 + 2^{\circ} 42'$, or $2^{\circ}\cdot42$ in excess. If we take the sixth fraction we shall find the result only $0^{\circ}\cdot03$ in defect. Hence, 235 years after a transit of Venus we may confidently expect another, and also after $235 + 8$, or 243 years; neglecting as we have done, and may safely do, the small alteration in the place of the node, that takes place in the interval of the transit.

662. A transit, however, may happen when the planet is in, or nearly in, the opposite node of her orbit. To find the time when it is probable that transits in the opposite node may happen, we have merely to find approximative values of $\frac{57551}{18000}$, which will be $\frac{3}{1}, \frac{16}{5}, \frac{227}{71},$

$\frac{470}{147}$, &c. Taking the third of these fractions,

we have $71 \times 575^{\circ}\cdot51 = 180^{\circ} \times 227 + 1^{\circ}\cdot21$; the fourth gives $147 \times 575^{\circ}\cdot51 = 180^{\circ} \times 470 - 0^{\circ}\cdot03$. Whence, supposing the earth, Venus, and the sun, to be exactly in a line, Venus being in one of her nodes, then, in 71 synodic periods, Venus will be $1^{\circ}\cdot21$ distant from the other node, and in 147 synodic periods, only about three hundredth parts of a degree distant from that node.

663. Did our limits permit, we should now enter upon the most difficult branch of the science, the Lunar Theory, but we must content ourselves with referring those who would acquaint themselves with this highly interesting subject, to the works of La Lande, La Place, and other foreigners, and to the astronomy of the late Professor Vince; more especially, however, to the elegant and masterly work of Professor Woodhouse.

664. Table of the Transits of Venus over the Sun's Disk, that will occur to the Year 3000.

SECT. VI.—PRELIMINARY OBSERVATIONS RESPECTING ECLIPSES.

666. Before we lay down rules for calculating eclipses, it is necessary to make a few general observations respecting their nature and causes. All the planets and satellites being illuminated by the sun, cast their shadows towards that point of the heavens which is opposite to the sun. This shadow is nothing but a privation of light, in the space hid from the sun by the opaque body that intercepts his rays. When the sun's light is intercepted by the moon, so that he appears covered in whole, or in part, to any part of the earth, he is said to undergo an eclipse; though, properly speaking, it is only an eclipse of that part of the earth where the moon's shadow or penumbra falls. When the earth comes between the sun and moon, the moon falls into the earth's shadow; and having no light of her own, she suffers a total and total eclipse from the interception of the sun's rays. When the sun is eclipsed to us, the moon's inhabitants, on the side next the earth, see her shadow like a dark spot travelling over the earth, about twice as fast as its equatorial parts move, and the same way as they move. When the moon is in an eclipse, the sun appears eclipsed to her inhabitants; totally to all those parts on which the earth's shadow falls, and of as long continuance as they are in the shadow.

667. Although all opaque bodies, on which the sun shines, have their shadows, yet such are the distances of the planets, and the size of the sun, that the primary planets can never eclipse one another. A primary can eclipse only its secondary, or be eclipsed by it; and never but when in opposition or conjunction with the sun. The primary planets are very seldom in these positions, but the sun and moon are so every month; whence one may imagine that these two luminaries should be eclipsed every month. But there are few eclipses in respect of the number of new and full moons; the reason of which we shall now explain.

668. If the moon's orbit were coincident with the plane of the earth, in which the earth always moves, and the sun appears to move, the moon's shadow would fall upon the earth at every change, and eclipse the sun to some parts

of the earth. In like manner, the moon would go through the middle of the earth's shadow, and be eclipsed at every full; but with this difference, that she would be totally darkened for above an hour and an half; whereas the sun never was above four minutes totally eclipsed to us by the interposition of the moon. But one half of the moon's orbit is elevated $5\frac{1}{2}$ degrees above the ecliptic, and the other half as much depressed below it; and when the sun and moon are more than 17° degrees from either of the nodes at the time of conjunction, the moon is then generally too high or too low in her orbit to cast any part of her shadow upon the earth: when the sun is more than 12° from either of the nodes at the time of full moon, the moon is generally too high or too low in her orbit to go through any part of the earth's shadow; and in both these cases there will be no eclipse.

669. But when the moon is less than 17° from either node at the time of conjunction, her shadow or penumbra falls more or less upon the earth, as she is more or less within this limit. And when she is less than 12° from either node at the time of opposition, she goes through a greater or less portion of the earth's shadow, as she is more or less within this limit. Her orbit contains 360° ; of which 17° , the limit of solar eclipses on either side of the nodes, and 12° , the limit of lunar eclipses, are but small portions; and, as the sun commonly passes by the nodes but twice in a year, it is no wonder that we have so many new and full moons without eclipses.

670. To illustrate this, let ABCD, plate V. fig. 9, be the ecliptic, RSTU a circle lying in the same plane with the ecliptic, and VXYW the moon's orbit, all thrown into an oblique view, which gives them an elliptical shape to the eye. One half of the moon's orbit, as VWX, is always below the ecliptic, and the other half, XYV, above it. The points V and X, where the moon's orbit intersects the circle RSTU, which lies even with the ecliptic, are the moon's nodes; and a right line, XEV, drawn from one to the other through the earth's centre, is the line of the nodes, which is carried almost parallel to itself round the sun in a year. If the moon moved round the earth in the orbit RSTU, which is coincident with the plane of the ecliptic, her

shadow would fall upon the earth every time she is in conjunction with the sun, and at every opposition she would go through the earth's shadow; and thus the sun would be eclipsed at every change, and the moon at every full.

671. But although the moon's shadow *N* must fall upon the earth at *a* when the earth is at *E*, and the moon in conjunction with the sun at *i*, because she is then very near one of her nodes; and at her opposition, *n*, she must go through the earth's shadow *I*, because she is then near the other node, yet, in the time that she goes round the earth to her next change, according to the order of *XYVW*, the earth advances from *E* to *e*, according to the order of *FGH*; and the line of the nodes *VEX*, being carried nearly parallel to itself, brings the point *f* of the moon's orbit in conjunction with the sun at that next change. The moon being then at *f*, is too high above the ecliptic to cast her shadow on the earth; and, as the earth is still moving forward, the moon at her next opposition will be at *g*, too far below the ecliptic to go through any part of the earth's shadow; for by that time the point *g* will be at a considerable distance from the earth as seen from the sun.

672. When the earth comes to *F*, the moon, in conjunction with the sun *Z*, is not at *k* in a plane coincident with the ecliptic, but above it at *Y*, in the highest part of her orbit; and then the point *b* of her shadow *O* goes far above the earth, as in fig. 2, plate IV, which gives an edge view of fig. 9. The moon, at her next opposition, is not at *o*, but at *W*, where the earth's shadow goes far above her, as in fig. 2, plate IV. In both these cases the line of the nodes is about 90° from the sun, and both luminaries are as far as possible from the limits of the eclipses. When the earth has gone half round the ecliptic, from *E* to *G*, the line of the nodes *VGX* is nearly, if not exactly, directed towards the sun at *Z*; and then the new moon *l*, casts her shadow *P* on the earth *G*; and the full moon *p* goes through the earth's shadow *L*; which brings on eclipses again, as when the earth was at *E*. When the earth comes to *H*, the new moon falls not at *m*, in a plane coincident with the ecliptic *CD*, but at *W* in her orbit below it; and then her shadow *Q*, see fig. 2, plate IV, goes far below the earth. At the next full she is not at *q*, fig. 9, plate V, but at *Y* in her orbit $5\frac{1}{2}$ degrees above *g*, and at her greatest height above the ecliptic *CD*; being then as far as possible, at any opposition, from the earth's shadow *M*, as in fig. 2, plate IV.

673. Thus when the earth is at *F* and *G*, the moon is about her nodes at new and full, and in her greatest north and south declination (or latitude as it is generally called) from the ecliptic at her quarters; but when the earth is at *F* or *H*, the moon is in her greatest north and south declination from the ecliptic at new and full, and in the nodes about her quarters. The point *X*, where the moon's orbit crosses the ecliptic, is called the ascending node, because the moon ascends from it above the ecliptic; and the opposite point of intersection, *V*, is called the descending node, because the moon descends from it below the ecliptic.

674. When the moon is at *Y*, in the highest

point of her orbit, she is in her greatest north latitude; and when she is at *W*, in the lowest point of her orbit, she is in her greatest south latitude. If the line of the nodes, like the earth's axis, was carried parallel to itself round the sun, there would be just half a year between the conjunctions of the sun and nodes. But the nodes shift backwards, or contrary to the earth's annual motion, $19\frac{1}{2}^\circ$ every year; and therefore the same node comes round the sun nineteen days sooner every year than on the year before. Consequently, from the time that the ascending node *X* (when the earth is at *E*) passes by the sun as seen from the earth, it is only 173 days (not half a year) till the descending node, *V*, passes by him.

675. Therefore, in whatever time of the year we have eclipses of the luminaries about either node, we may be sure that in 173 days afterward we shall have eclipses about the other node. And when at any time of the year the line of the nodes is in the situation *VGX*, at the same time next year it will be in the situation *rGs*; that is, the ascending node having gone backward, that is, contrary to the order of signs, from *X* to *s*, and the descending node from *V* to *r*; each $19\frac{1}{2}^\circ$.

676. At this rate the nodes shift through all the signs and degrees of the ecliptic in 18 years and 225 days; in which time there would always be a regular period of eclipses, if any complete number of lunations were finished without a fraction. But this never happens; for if both the sun and moon should start from a line of conjunction with either of the nodes in any point of the ecliptic, the sun would perform 18 annual revolutions and 222° over and above, and the moon 230 lunations and 85° of the 231st by the time the node came round to the same point of the ecliptic again; so that the sun would then be 138° from the node, and the moon 85° from the sun. But in 223 mean lunations, after the sun, moon, and nodes, have been once in a line of conjunction, they return so nearly to the same state again, as that the same node, which was in conjunction with the sun and moon at the beginning of the first of these lunations, will be within $28' 12''$ of a degree of a line of conjunction with the sun and moon again, when the last of these lunations is completed. And therefore in that time there will be a regular period of eclipses, or return of the same eclipse, for many ages.

677. In this period, which was first discovered by the Chaldeans, there are 18 Julian y. 11d. 7h. 43m. 20s., when the last day of February in leap years is four times included; but when it is five times included, the period consists of only 18y. 10d. 7h. 43m. 20s. Consequently, if to the mean time of any eclipse, either of the sun or moon, you add 18 Julian y. 11d. 7h. 43m. 20s., when the last day of February in leap-years comes in four times, or a day less when it comes in five times, you will have the mean time of the return of the same eclipse. But the falling back of the line of conjunctions, or oppositions of the sun and moon $28' 12''$, with respect to the line of the nodes in every period, will wear it out in process of time; and after that it will not return again in less than 12,492 years.

678. These eclipses of the sun, which happen about the ascending node, and begin to come in at the north pole of the earth, will go a little southerly at each return, till they go quite off the earth at the south pole; and those which happen about the descending node, and begin to come in at the south pole of the earth, will go a little north at each return, till at last they quite leave the earth at the north pole.

SECT. VII.—OF CALCULATING ECLIPSES.

679. The chief things to be considered in the calculation of eclipses are, the magnitudes of the shadow and penumbra of the opaque body, and the ecliptical limits, or the distance from the node, when an eclipse of the sun or moon will happen. These must be calculated both for lunar and solar eclipses. The operations may be performed as follows:—

I.—FOR LUNAR ECLIPSES.

680. In plate VIII. fig. 3, let AB be the sun, and CD the earth. Draw AC, BD, by the edges of the sun and earth, which will meet in a point V, because the sun is bigger than the earth. Through the centres of the sun and earth, S and T, draw STV. Also draw BCE, ADF, touching the contrary sides of the sun and earth, intersecting in P; also draw SC and CT. If the whole figure be turned round about the axis SV, the lines AV, BV, APF, BPE, will generate the two cones CVD, EPF; the cone CVD, is the dark shadow of the earth, EPF continued, is the penumbral cone. And beyond V, the section of the cone EPF, will be all in the penumbra.

681. Hence, 1. Half the angle of the cone of the earth's shadow CVT, is equal to the sun's apparent semidiameter, less his horizontal parallax. For in the triangle SCV, the external angle SCA = CVS + CST. And CST is the sun's parallax. Therefore CVT = SCA - CST.

682. 2. Half of the angle of the earth's penumbral cone CPT, is equal to the sun's semidiameter on Earth's orbit + parallax. For in the triangle CSP, the external angle CPT = PCS + CST.

683. 3. Hence, 1. The angle of the earth's penumbral cone CPT, is equal to half the angle of the dark cone CVT + twice the sun's horizontal parallax CST.

684. 4. The apparent semidiameter of the earth's dark shadow IK, upon the moon's orbit, is equal to the sum of the horizontal parallaxes of the sun and moon, less the sun's apparent semidiameter. For the angle ACI = CIT - CAI = CIT - SCA + CST.

685. 5. The apparent semidiameter of the earth's penumbra, GI, upon the moon's orbit, is equal to the sum of the horizontal parallaxes of the sun and moon + the sun's apparent semidiameter. For in the triangle PCI, the external angle PCI = CIT + CPT = CIT + PCS + CST.

686. 6. Hence to find the length of the earth's shadow. In the triangle CTV there is given

the angle V = sun's apparent semidiameter — his parallax, and CT the earth's radius, to find TV.

II.—FOR THE SHADOW AND PENUMBRA, IN SOLAR ECLIPSES.

687. In plate IV, fig. 10, let AB be the sun, KL the moon, CD the earth. Draw the tangents AK, BL, by the edges of the sun and moon, on the same side, to meet in V; and BK G, ALH to touch the contrary sides. Draw SK, IK; and through S and I, the centres of the sun and moon, draw the axis SIV. Then if the whole figure AKVLB be turned about the axis SV, the sides AV, BV, and PH, PG, will generate two cones KVL, GPH. The cone KVL is the dark shadow of the moon, and the cone GPH is the moon's penumbral cone. Hence,

688. 1. The angle of the cone of the moon's shadow KLV, the angle of the penumbral cone KPL, the angles GKV, and HLV, are each equal to the sun's apparent diameter AKB, very nearly; and half the angle of either cone P or V is equal to the sun's apparent semidiameter. For by reason of the great distance of the sun from T, in respect of TP, TV, TI; the apparent diameter of the sun, seen from any of the places V, T, I, P, K, will be the same, that is, the angles AVB or KVL, APB or KPL, AKB or GKV, ALB or VLH are all equal; differing only by the angle KSI, which in the moon is insensible.

689. 2. The height of the cone IP is equal to the cone VI. And KPL, KVL, are equal and similar. For the angles at P and V are equal; and KL is common.

690. 3. The apparent semidiameter of the moon's dark shadow QO, upon the earth at O, seen from the moon, is equal to the moon's apparent semidiameter—the sun's apparent semidiameter. And if the sun's apparent semidiameter be greater, the shadow does not reach the earth. For draw KO; then in the triangle KOV, VKO = KOS - KVS = KOI - AVS = KOI - $\frac{1}{2}$ the sun's apparent diameter.

691. 4. The apparent semidiameter of the moon's penumbra GO, upon the surface of the earth, as seen from the moon, is equal to the sum of the apparent semidiameters of the sun and moon. Draw GI and TGR. Then in the triangle GPI, the external angle GIO = GPI + PGI = KPI + KGI = KPI + KOI = AKS + KOI.

692. 5. Hence, to find the length IV of the moon's shadow. In the triangle KVI, there is given the angle KVI = half the sun's apparent diameter, and KI the earth's radius; whence VI will be had; and to find the arch QN of the earth, involved in the moon's dark shadow. In the triangle QVT, we have given TV the difference between the moon's distance from the earth, the height of the shadow; and the angle QVO = the sun's apparent diameter, and TQ the radius of the earth; to find the angle TQV, to which add QVT, and the sum is the angle QTO or arch QO; and doubled gives the whole arch QN.

693. 6. To find the arch of the earth GI involved in the penumbra; say, as the earth's radius GT: to S. of the sun's apparent semidia-

meter : : so is PT the sum of the moon's distance and cone's height: to S.T.G.P or R.G.K. From this take the sun's apparent semidiameter, and there remains G.T.O = G.O, which doubled gives G.H. For in the triangle G.P.T, there is given the angle P = the sun's apparent semidiameter, and P.T the moon's distance and height of the cone, and T.G the earth's radius; to find the angle R.G.K = G.P.T + P.T.G. Therefore P.T.G or O.T.G = R.G.K - G.P.T = R.G.K - the sun's apparent semidiameter.

III. TO FIND THE ECLIPTICAL LIMITS.

694. An eclipse of the moon can only happen, when the distance of the centres of the moon, and of the earth's penumbra, is less than the sum of their semidiameters. For if the distance is greater, the moon and penumbra cannot touch one another.

695. An eclipse of the sun cannot happen unless the distance of the centres of the sun and moon, be less than the sum of their semidiameters, when seen from a certain place. That it shall appear in no place, the moon's parallax must be added to the sum of the semidiameters.

696. In lunar eclipses, therefore, the moon's latitude must be less than the sum of the semidiameters of the moon and of the earth's penumbral shadow, taken at the moon's orbit. And in solar eclipses, the moon's latitude must be less than the sum of the sun's and moon's semidiameters added to the moon's horizontal parallax; that the eclipse may be visible some way: or without the parallax, to be visible in a certain place.

697. Therefore in the right angled spherical triangle, plate IV, fig. 4, Ω S.M, having the angle Ω , and the distance S.M, the distance of the sun from the node, Ω S will be known, or the ecliptic limits. The mode of finding which, may be seen from the following

EXAMPLE.

Mean apparent semidiameter of the sun	16	4
Parallax of the sun		12
Mean apparent semidiam. of the moon	15	38
Parallax of the moon		59 5
Inclination of the moon's orbit	5	8 30

Hence will be obtained,

The semidiameter of the earth's penumbra	1	13 21
The semidiameter of the moon and earth's shadows		56 51
The semidiameter of the sun and moon	31	42
The same with the parallax	1	28 47

In the triangle Ω S.M for the eclipse of the moon.

Here S.M = $1^{\circ} 13' 21'' + 15 38'' = 1^{\circ} 28' 59''$.	
S. Ω = 5 $8\frac{1}{2}$	8.952398
S.S.M = 1 28 59	8.413067
Radius	10.

S. Ω S = 16 47 9.460669
the limit for the lunar eclipse at a medium.

In the triangle Ω S.M for the eclipse of the sun.

Here S.M = $1^{\circ} 28' 47''$.	
S. Ω , = 5 $8\frac{1}{2}$	8.952398
S. S.M = 1 28 47	8.412009
Radius	10.

S. Ω .S. = 16 15 9.459611

the limit for the solar eclipse, in any place; about the same as for the lunar. But for a particular place, S.M = 31 42; and S Ω comes out only $5^{\circ} 54'$ for the limit.

698. 1. Hence there will at least be four eclipses in a year, taking one year with another; two of the moon, and two of the sun. For $16^{\circ} 47' + 16^{\circ} 45' = 33^{\circ} 32'$ or $32\frac{1}{2}^{\circ}$. Therefore the sun stays above a month within the ecliptic limits twice in the year. During which time the moon makes two revolutions, and therefore must cause two eclipses, either time; one of the moon, and another of the sun.

699. 2. Half of the eclipses will, in general, be invisible at any given place. And consequently one year with another there can only be two visible eclipses in a year, the one lunar and the other solar. For the sun and moon spend as much time below the horizon as above it.

700. 3. The ecliptical limits may be found for total eclipses, as well as for partial ones, by the same method; i. e. by taking S.M = the difference of the semidiameters of the earth's dark shadow and of the moon, in lunar eclipses; or = the difference of the semidiameters of the moon and sun, in solar eclipses.

701. 4. Eclipses do not always happen in the same places of the zodiac; but in places more and more westward. For the eclipses being about the nodes, and the nodes regressive at the rate of nineteen degrees in a year; the places of the eclipses are nineteen degrees more west every succeeding year.

702. From these premises it will be necessary, in calculating a particular eclipse, to consider the angle that the moon's way makes with the sun at the time of an eclipse. See plate XI. fig. 4. Let Ω S be the ecliptic, Ω M the moon's orbit, Ω the node. And let S be the sun, in the solar eclipse; or the centre of the earth's shadow, in the lunar; and M the moon at the time of the syzygy. Take Ω A to Ω S as the sun's horary motion, to the moon's, at that time; draw M.A, then M.A.S is the angle required; and A.M the moon's apparent orbit.

703. For by construction, in the time that the moon has been moving from Ω to M (that is, through Ω S reckoned in the ecliptic,) the sun has moved through a space D.S equal to Ω A. Therefore the sun was in D, when the moon was in the node at Ω . Draw D.B, M.B parallel to S.m, S.D; and draw B Ω , which will be parallel to M.A. Now since the moon makes the same latitude D.B or S.M, in the same time, whether the sun moves or stands still; and since S.M is her latitude, when the sun is at S, D.B (equal to S.M) will be her latitude, supposing the sun had stood at D, without any motion towards S; and consequently Ω B will be her apparent way, to an eye at D, through which she seems to move in the same time. Or, which is the same thing, A.M will be her apparent way to an eye fixed at S.—For the triangles A.M.S are Ω B.D are equal; and M.A.S is the angle of her way with the ecliptic. By the theory of relative motions, in bodies moving the same way, all the apparent motions are the same, as if one body stood still and the other moved forward, with the difference of their motions. And here Ω D or A.S is the difference of their motions supposing S to be fixed

704. Hence, as the moon's horary motion : to the sun's horary motion :: SQ the distance from the node to AQ . Then $SA = SQ - AQ$. As sine of SA : rad :: tangent moon's latitude SM : tangent angle A .

705. It is the apparent orbit AM that must be made use of, in calculating all the particulars of an eclipse. For an observer considers not S as moving; and therefore only the relative motions are concerned. To calculate, therefore, an eclipse of the moon, the following rules will be found useful.

IV. RULES FOR CALCULATING LUNAR ECLIPSES.

706. 1. Find the true time of the opposition, when an eclipse is to happen; and let that be reduced to apparent time.

707. 2. Find the true places of the sun and moon, when in opposition : 2. The sun's mean anomaly, and the place of his apogee : 3. The place of the moon's ascending node, and of her apogee, and her latitude.

708. 3. Let QS , fig. 1, plate VIII. be a part of the ecliptic; QM the moon's orbit; S the centre of the earth's shadow, and M the moon, when in opposition. Take QA , to QS which is known by calculation : as the sun's horary motion, to the moon's; which are known from the astronomical tables. Draw AM , for the way of the moon from the sun. Then in the right angled spherical triangle ASM , there is given $AS = QS - QA$; and SM the moon's latitude found by calculation : to find the angle SMA .

709. 4. Let SP fall perpendicular to AM ; then since the arches SM , MP , SP , are very small, they may be taken for right lines; and the triangle MP for a plane triangle. Then having SM and angle $SM P$; MP and SP will be found, where P is the place of the moon in the middle of the eclipse. Likewise the time of the moon's moving through MP will be known by her horary motion; and from thence the time when she is at P , or the middle of the eclipse.

710. 5. From the astronomical tables, find the sun and moon's apparent semidiameters, for the time of opposition; and their horizontal parallaxes.

711. 6. From any convenient scale of equal parts, with the centre P and radius PB , equal to the arches contained in the moon's radius, describe the circle BCD for the moon. And with the radius SD equal to the sum of the sun and moon's horizontal parallaxes; the sun's semidiameter, all in minutes,) describe the circle DEB , from the centre S , then this circle will represent the earth's dark shadow. Likewise with the same centre S , and radius SF equal to the sum of the sun and moon's parallaxes + the sun's semidiameter, in minutes,) describe the circle $FQCE$; and this will be the earth's penumbra.

712. 7. These rates being observed, it will be easy to find all the requisites by scale and compasses, or by measuring the arc; or rather by computing in the several right angled plain triangles, contained in the same. Thus, to find when the moon first touches the penumbra at K , draw the right angled triangle SPK , there is

given SP , and SK (the sum of the radii SL and PB), to find PK . Which being known, the time of the moon's passing through it will be known, by the moon's horary motion from the sun.

713. To find when the moon first enters the dark shadow of the earth in D : in the right angled triangle SPD , there is given SP , and SD , (the sum of the radii SD , PB), to find PD ; and consequently the time of half the duration in the shadow.

714. To find the digits, or 12th parts of the moon eclipsed. Here no the part eclipsed is =

$$Sn + Po - SP; \text{ and } \frac{12 no}{2Po} \text{ or } \frac{6 no}{Po} \text{ is the number}$$

of digits eclipsed. In total eclipses of the moon, the earth's shadow often reaches farther than the moon. And then more than twelve digits are said to be eclipsed, supposing the moon's disk to be produced so far.

715. To find the time when the moon wholly enters into the dark shadow BED , follow the same method as when it entered into the penumbra GQF . This will be evident, by supposing GQL the dark shadow. In that case SI will be the difference of the semidiameters of the moon and dark shadow. The times of passing through PI , PK , &c. being known, and the time of the middle of the eclipse at P , the beginning and end will be known.

716. 8. Hence, if the moon or circle CBQ never touches the circle GQF , there will be no eclipse, not even by the penumbra. And if the same circle never touches the circle BDE , there will be no part of the moon totally eclipsed. And if the whole circle CBQ enter into the circle BED , the whole moon will be totally eclipsed; and that is when SP is less than the difference of the semidiameters SD and PB . If the point S be in the node, then P falls upon S , and the eclipse is central. When only a part of the circle CBQ goes into the circle BED , the eclipse is a partial one, as in this figure.

717. 9. The time of the eclipse being known for any particular place, it is easy to know if it be visible at that place, by knowing if the moon be risen. Or the place will be known where the moon is vertical; and therefore it will be visible to all places within a quadrant's distance from it.

718. 10. If the spectator live in the place, (or in the same longitude) which the tables are calculated for; he will see the eclipse at the time determined by the calculation. If not, he will see it an hour sooner for every 15° difference of longitude, that he lives west from it. And so much later, if he lives eastward; that is, in the way of reckoning time. But in regard to absolute time, it is seen from all places at the same instant.

EXAMPLE.

To find the time of the Lunar Eclipse, December 13th, 1769; its Duration and Digits eclipsed.

719. 1. The mean time of the syzygies, by the tables, is found to be December 12d. 19h. 27m. at which time the moon's horary motion from the sun is $35' 33''$. At this time, computing the true places of the sun and moon, the moon will

appear to be 35 10" before the sun. And therefore the time is past the syzygy, 59m. 12s. Therefore,

From	1d.	19h.	27m.	0s.
Take	0	0	59	12
True time	1	18	27	48

The places being computed again, the moon is only 7" before the sun, which amounts to 12" of time; therefore the time of opposition is 12d. 18h. 27m. 36s. which reduced to apparent time is December 12d. 18h. 32m 51s.

2. The sun's place is	8s.	21°	37'	35"
The moon's place	2	21	37	35
Place of the ascending node	8	14	46	13
Her latitude south			37	58
The sun's horary motion			2	33
The moon's horary motion			38	6

3. Hence the moon is 6° 51' 22" past the descending node: that is $\angle S = 6^\circ 51' 22''$. Therefore $\angle A = 17' 32''$, and $\angle S = 6^\circ 23' 50''$. Therefore the angle $\angle S M A = 84^\circ 22' 28''$.

4. Hence drawing the ecliptic RS, and SM perpendicular to it, and equal to 37' 58" from a scale of minutes, as in fig. 12, plate IX. and making the angle $\angle S M A = 84^\circ 22\frac{1}{2}'$. We find the perpendicular $S P = 7' 47''$, and $M P = 3' 43''$. And therefore, the horary motion of the moon from the sun being 35' 33", PM will be passed over in 6' 17". And since this is before the opposition at M, this time must be deducted from the time of opposition. And the time of the middle of the eclipse will be December 12d. 18h. 26m. 34s.

5. The sun's apparent semidiameter	16' 20"
His horizontal parallax	12
The moon's apparent semidiameter	16 48
Her horizontal parallax	61 7
6. Hence the radius BP	= 16' 48"
radius SD	= 44 59.
radius SF	= 77 39.
7. Hence also PK or Pk	= 86 34.
and PI or Pi	= 48 53.

and therefore the time of passing through PK is 2h. 26m. 6s., and through PI = 1h. 22m. 30s. And the whole duration in the shadow from I to i, is 2h. 45m. And the digits eclipsed $8\frac{1}{2}$ on the upper side. Whence,

	D.	H.	M.	S.
First entering the penumbra				
December	13	4	0	28 morn.
Entering the dark shadow at	0	5	4	4
Middle	0	6	26	34
Opposition	0	6	22	51
Leaving the shadow	0	7	49	4
Leaving the penumbra	0	8	52	40
Duration	0	2	45	0
Digits eclipsed $8\frac{1}{2}$				

720. All these calculations may be made sufficiently near, by scale and compasses, in a large draught; making use of a scale of minutes and sixtieth parts; or rather by making a scale of time answering thereto, by the help of the horary motion of the moon from the sun. For by this scale, the several hours and minutes may be marked along the line Ak, by which it will ap-

pear at what time the centre of the moon is at any given point. For the time is known when the moon is at M, and from thence the points at each hour and minute are easily found. And this construction, with only right lines and circles, will be exact enough in a large figure; for the best lunar tables give the times of the phases of an eclipse no nearer than to four or five minutes of time; and therefore such a construction is sufficient to answer the purpose. Hence it may be observed, that no eclipse of the moon can last above five hours and a half from the moon's first touching the earth's penumbra, to its last leaving it. For $SK = 94' 27'' = 94.45$, and the horary motion is $35' 33'' = 35.55$ and $\frac{94.45}{35.55} = 2.66 = 2h. 39m. =$ semiduration: and no eclipse of the moon, by the earth's shadow, can last above $3\frac{3}{4}$ hours. Nor when total, above $1\frac{3}{4}$ hours. For $SI = 61' 47'' = 61.78$, and $\frac{61.78}{35.55} = 1.745 = 1' 45'' =$ the semiduration, and $SD - SI = 28' 11'' = 28.18$, and $\frac{28.18}{35.55} = .79 = 47m.$ the semiduration.

721. The refraction of the earth's atmosphere, in lunar eclipses, makes the shadow less; by bringing the rays, which terminate the shadow, sooner to a point. And hence comes that red color of the moon even in total eclipses. But that light must be very dim, by reason of a great number of the rays being stopt and lost in the earth's atmosphere.

722. The circles terminating the shadow and the penumbra BED and GQF, cannot be distinguished.* For the darkness from BED, diminishes by insensible degrees, to GQF, being darkest at E, and lightest at Q, where it vanishes insensibly. And therefore the moon does not appear to be eclipsed till she is a good way within the penumbra. For that reason, there may happen eclipses of the moon which cannot be discovered as such.

723. All lunar tables show the moon's place in eclipses, more truly in the syzygies than in the quadratures, or any other place. For the times of the syzygies, and the moon's place, have been more accurately observed in eclipses, than at any other time; and from thence the moon's theory has been deduced. Besides, many of the inequalities cease in the syzygies, but have sensible effects in other places; becoming greater, as the moon is further from the syzygies; being greatest in the quadratures. Whence the lunar tables do not determine the moon's place truly in the quadratures. And her place calculated from these tables is not so exact in the quadratures as in the syzygies.

724. Several inequalities depend on the aspect of the nodes and the sun; but these cease when the nodes are in the syzygies. When the moon and the nodes are in the syzygies, the moon's place, then wanting fewer equations, as being subject to fewer inequalities, will be more correct than when she is in other places, where there are more and greater inequalities, and more equations. From hence more errors will happen out of the syzygies than in them.

V.—TO FIND THE WAY OF THE MOON FROM THE SUN, IN A SOLAR ECLIPSE, SUPPOSING THE OBSERVER AT REST.

725. Let HZO , in plate IX. fig. 6, be the meridian of the place, HO the horizon, EC the equinoctial, EL the ecliptic, Z the zenith, P the pole, S and M the places of the sun and moon in conjunction, PSD the sun's meridian. Having found the sun's distance from the node, QS , and the moon's latitude SM , &c. take QAQ to S , as the sun's horary motion to the moon's horary motion; then SA is known. Draw MA ; then in the spherical triangle ASM , right angled at S , there is given SA , SM ; to find the angle SMA ; A being the moon's way from the sun.

726. But, as the eye of the observer is in motion, by the rotation of the earth, which gives an apparent motion to the moon, contrary to that of the observer, we must find the quantity and direction of that motion. As the observer is carried eastward, towards the point C , the apparent motion of the moon caused thereby will be in the line CS . And to determine the position of C , in respect of AM or SM , several spherical triangles must be resolved, as follows:

727. In the right-angled triangle EDS there is given ES , and angle E to find DS , and angle ESD or ASP ; or these may be easier had from the astronomical tables. And in the triangle ZPS , there is given PS (the complement of DS), the angle ZPS (from the time of the day), and ZP the complement of the latitude; to find ZS , and angles PZS and ZSP . Then ZSP and ASP being known, ZSA will be known. And MSA being a right angle, ZSM will be known. In the right angled triangle CPS , there is given CS , the measure of the angle FZC (the difference between the angle PZS and the right angle CZP), and SP the complement of ZS ; to find CS , and the angle CSF or BSZ . Then BSZ and ZSM being known, BSM will be known. And SMA being known, its supplement SMB is known, and consequently the angle SMB .

728. To find the quantity of the motion. That along AM is already known; and to find the apparent motion along SB . The sine of 15° (the horary motion of a point in the equinoctial), is $\cdot 259$ to the radius 1. And if h be the moon's horizontal parallax, then the radius of the earth appears at the moon under the angle h , and therefore 15° of the equinoctial appears under the angle of $\cdot 259h$; this then is the horary motion of a point in the equinoctial, viewed directly from the moon. And the moon's apparent motion seen from that point in the equinoctial is the very same. But this motion is to be diminished upon two accounts. 1. Because it is less in a circle, in proportion to the cosine of the latitude. And 2. Upon account of the obliquity of the motion, when not perpendicular to the rays of the sun; and this will be as the sine of CS , the sun's distance from the east or west point of the horizon. Therefore to find the quantity of this motion.

To the logarithm of $\cdot 259h$

Add the cosine Latitude.

And the sine of CS

Then the sum, abating twice radius, is the logarithm of this apparent horary motion. Then this motion is to be compounded with the motion along AM as follows:

729. Let AS , plate IX. fig. 5, be a portion of the ecliptic, SB the way of the apparent motion, MA the moon's way from the sun. Draw NM parallel to SB ; and let MN be the horary motion along SB or MN , and MI the horary motion of the moon from the sun. Then complete the parallelogram $NMIQ$; draw the diagonal MQR , which is the direction of the motion, compounded of the observer's and the moon's motions, and MQ is the total apparent horary motion, supposing the observer at rest. Then in the plain triangle QMI , there is given MI , and IQ (or MN), and the angle $MIQ = MBS$; to find the angle QMI , and side MQ or the absolute horary motion. And the angles QMI and IMS being known, QMS is known.

730. If the sun be in the eastern hemisphere, in which case the concave side of the eastern hemisphere is here projected (in fig. 6), then the moon's motion from the sun is from M towards A , and the other apparent motion from S towards B , or from M towards N . But if the sun is in the western hemisphere, this projection represents the convex side of the sphere; and then the moon moves from the sun, in direction AM , and the other apparent motion is from S towards C , being contrary.

VI.—TO CALCULATE SOLAR ECLIPSES.

731. The eclipses of the sun are more difficult to calculate than those of the moon; the latter being clear of parallaxes, which the former are incumbered with, which gives a great deal of trouble. But a great part of it may be avoided by using projections instead of calculations. The rules are,

732. 1. Find the true time of the conjunction, and the places of the sun and moon at that time.

733. 2. Having found the way of the moon from the sun by projection or calculation; find, by the astronomical tables, the moon's horizontal parallax, her apparent diameter, and horary motion, also the sun's apparent diameter and horary motion. But, to avoid a great deal of calculation, if the sphere be projected by a large scale, it will give all the requisites with sufficient exactness, by measuring the several angles and sides, without any calculation, or very little. And here it is best to project the concave side, and then every thing appears as it is in nature.

734. 3. Find the moon's parallax of altitude, by making as rad. : cos. altitude : : so the moon's horizontal parallax : to her parallax of altitude Vt or Mm . fig. 8. Then find her parallax of latitude Mm , and longitude Ss , or mn , and from thence her apparent latitude and longitude is known.

735. 4. Draw the line SL , fig. 10, for the ecliptic, and from a large scale of minutes, erect SM perp. to LS , and equal to the apparent latitude; make the angle SMR , as found in the last prob. and draw QR for the moon's apparent path. From S let fall SP perpendicular to MR , and SP will be the least distance of the centres of the sun and moon, or the middle of

the eclipse. From the centre S, with the radius equal to the minutes contained in the sun's semidiameter, describe the circle ABC for the sun. And from the centre P, with the radius equal to the moon's semidiameter, describe the circle AOC D for the moon. If these circles do not intersect, there will be no eclipse. But if they intersect, an eclipse must necessarily happen.

736. 5. Then P is the place of the moon in the middle of the eclipse. Make SI and SK equal to the sum of the semidiameters of the sun and moon; and the moon's centre will be at I when the moon first touches the sun, or at the moon's centre, at the end of it. In the triangle P S I, there is given SI, SP; to find PI = PK, which reduced to time by help of the moon's apparent horary motion, shews half the duration of the eclipse; and consequently we shall have the beginning and end.

737. 6. And to find the quantity no , or the digits eclipsed; we have $no = Sn + Po - SP$, and $\frac{6no}{Po} =$ number of digits.

738. 7. The time found being mean time, it must be reduced to the common or apparent time, by the equation of time. And if the given place be not that for which the tables are made, add so much time, if the place lie eastward, to the time of conjunction, as answers to the difference of meridians; or subtract it if it lie westward.

EXAMPLE.

TO FIND THE TIME OF THE SUN'S ECLIPSE, JUNE 4, 1769, ITS DURATION AND DIGITS ECLIPSED AT LONDON.

739. 1. By the tables the mean time of the conjunction is found to be June 2d. 20h. 41m. And hence, the true time of conjunction is June 3d. 20h. 27m. 43s. And their places are $2^{\circ} 13' 51'' 25''$. And the moon's lat. $55^{\circ} 32'$ north. The moon's motion from the sun $35^{\circ} 47'$.

2. In fig. 5 and 6, Plate IX. the angle AMS = $84^{\circ} 47'$. ZSM = $35^{\circ} 20'$. CSF = $5^{\circ} 18'$. SBM = $43^{\circ} 49'$. SF = $42^{\circ} 16'$. CF = $3^{\circ} 34'$. CS = $42^{\circ} 24'$. The angle QMI = $8^{\circ} 25'$. SMQ = $92^{\circ} 52'$. MN or IQ = $6^{\circ} 38'$. MQ = $31^{\circ} 20'$. Also

The moon's horizontal parallax . . .	60' 58"
Her apparent diameter	33 32
Her horary motion	38 10
The sun's diameter	31 41
His horary motion	2 23

3. In fig. 4, the moon's parallax in altitude Mn is $45^{\circ} 09''$; her parallax in latitude Mn, $38^{\circ} 05''$; her remaining latitude Sn, $17^{\circ} 26''$; her parallax in longitude Ss, $24^{\circ} 13''$; which is increased so much.

4. Draw SL for the ecliptic, as in fig. 10, at any point S, erect the perp. MS equal to $17^{\circ} 26''$, the moon's apparent latitude; through M draw the moon's way QMR, making the angle SMR = $92^{\circ} 52'$. Draw SP perp. MR, which here falls very near M. From the centre S, with the radius SA = $15^{\circ} 50''$, describe the circle ABC for the sun. And with the radius MD = $16^{\circ} 46''$, and centre P, describe the circle ADCO for the moon.

5. Hence PI or PK = $27^{\circ} 33''$. And the time of moving through IP or PK, at the rate

of $31^{\circ} 20''$ an hour, is $52^{\circ} 45''$ for the semiduration. By reason of the parallax ($24^{\circ} 13''$), she is past the apparent conjunction; the difference being what the parallax causes, which comes to $47^{\circ} 23''$. Therefore the middle of the eclipse is so much sooner, being at 3d. 19h. 41m. 20s. This reduced to apparent time is 3d. 19h. 43m. 27s. for the middle.

6. The digits eclipsed are $5 \frac{4}{10}$, nearly.

740. In this example, the concave side of the sphere is projected, which suits best to the appearance of the heavens. And the figures are drawn upon that supposition. It appears from the process, that the moon is advancing to her descending node, and therefore has north latitude. And by the position of that part of the ecliptic, her parallax in longitude, advances her so much forward, viz. $24^{\circ} 13''$. And therefore she is so much past the apparent conjunction. Hence we gain these several particulars, as to the eclipse:

	D.	H.	'	"
741. 1. The begin. June, morn.	4	6	53	42
middle	4	7	43	27
end	4	8	46	12
total duration	1	45	30	

digits eclipsed $5 \frac{1}{2}$, on the upper side of the sun, towards the left; as appears by the figure.

742. 2. Hence the position of the horns at C and A, are easily found in the middle of the eclipse. For they are in a position parallel to RI, the moon's way.

743. 3. The middle of the eclipse will not be at the same time in all places of the same longitude; for the parallax of longitude will be different in different places.

744. No eclipse of the sun can last above two hours. For SI or SA + MD = $32^{\circ} 26'' = 32.6$ and the horary motion = $34^{\circ} 47'' = 35.78$.

And $\frac{32.6}{35.78} = .91 = 54 \frac{1}{2}$ minutes, for the semiduration.

745. If it were not for the parallax, eclipses of the sun would be as easily calculated as those of the moon. And in order to get the parallax, the angle ZSM and SP must be known, fig. 2, which occasions the resolving several spherical triangles before they can be had. Likewise it may be observed, that the apparent way of the moon is strictly curve line, concave towards S, which arises from the parallel of latitude being a curve, and the moon being out of its plane. Likewise the moon's apparent velocity is something greater at the beginning than at the end.

VI.—RULES FOR CALCULATING A GENERAL ECLIPSE OF THE SUN.

746. The elements necessary for this are: 1. The sun and moon's place, and the time at the true conjunction; 2. The moon's latitude, horizontal parallax, diameter, and horary motions; 3. The sun's declination, diameter, and horary motion; and 4, the angle the moon's way makes with a circle of latitude.

747. 2. From a large scale of minutes, take the moon's horizontal parallax in the compasses, and at any point C, in the right line BD, (which represents the ecliptic in plate XI. fig. 6), describe the circle ABED, for the earth's disk, or the earth's flat face as it appears at a distance. in

a line drawn to the sun. Draw CM perpendicular to CD , and equal to the latitude of the moon upwards, if north. Make the angle CMG equal to that which the moon's way makes with a circle of latitude; acute to the right hand, if she tend to the node; or obtuse, if she be past it; and drawing FMG , it will be the way of the centre of the moon's shadow upon the earth. From C let fall CH perpendicular to FG . Then at H will be the middle of the earth's eclipse.

743. 3. With the centre H , and radius HO , equal to the sum of the semidiameters of the sun and moon, describe the circle QOR , which will be the moon's penumbra. Also describe a small circle round the centre H , whose radius is the difference of the sun and moon's semidiameters, that little circle will be the dark shadow of the moon. Then all the countries of the earth contained in the segment VAW will be successively eclipsed by the penumbra, as the shadow moves along the tract FG ; while the other segment VEW suffers no eclipse at all. All places in the line st will be totally eclipsed, as the dark shadow, or the small circle at H passes successively over them. But this circle, or dark shadow, being very small, a total eclipse at any place continues but a small time. Sometimes the sun's semidiameter exceeds the moon's; and then there will be no dark circle, or total eclipse, but a lucid ring will appear about the moon in these places, and this is called an annular eclipse. The difference between the semidiameters of the sun and moon is so little, that no total eclipse lasts above four minutes.

749. 4. Draw CF , $CG =$ sum of the semidiameters of the sun and moon, and the moon's parallax; then the moon's shadow will touch the earth at L and K , where the eclipse begins and ends. In the triangle CFH , there is given CF , CH ; to find $FH = HG$, which, converted into time, gives half the duration, or half the time that the moon's shadow is upon the earth. Also NO measured, shews how far the eclipse reaches; or CO measured, does the same. It may be sufficient to measure all these by the scale without calculation.

750. 5. To find the pole. Draw the arch AP , making the angle KAP equal to the sun's longitude, and AP the distance of the poles of the equator and ecliptic, $23\frac{1}{2}$; then P is the pole. For AP is a part of the solstitial colure, and passes through Cancer and Capricorn. And CAP is what the sun wants of Cancer, therefore PAK is what it is past Aries. Through P draw CPT . And here we may suppose that the pole P is fixed during the time of an eclipse. Then in the right angled spherical triangle APT , there is given AP and the angle A , to find AT or angle ACP . In this triangle PT is the sun's declination, and APT or CPK his right ascension from Cancer. Here note, that any place in the line CT is in the sun's meridian; and C is the place where the sun is vertical at the time of the eclipse.

751. 6. To find the situation of any given place, at a given hour. Make the angle CPX (with the sun's meridian), equal to the time from noon; on the left hand, if it is before noon. And make PZ the complement of the latitude: then

Z is the place required. And if it falls in the penumbra, it is eclipsed; or anywhere in the segment VAW ; if its motion in the parallel circle does not carry it out, before the penumbra reaches it.

752. 7. To find the place which is first or last touched by the penumbra, as K . Draw the arch PK . In the triangle GCA , there are given CG and CH , to find the angle GCH , from which subtract HCP which is known, gives the angle PCK or TK . Then in the right-angled spherical triangle PTK , there is given TK , and PT the sun's declination; to find PK the complement of the latitude of K , and TPK or CPK the difference of longitude of K , and the sun.—Therefore its longitude and latitude is obtained. In the same manner may be found that of L . And by the same method the latitude and longitude of the places s and t may be found, where the dark shadow first enters the earth's disk, or quite leaves it. Thus also may be found the place which is in the line FH , at any point of time: or if the place be given, what the time will be; and that by help of the horary motion, with other particulars of like nature.

753. 8. The part of the sun's diameter eclipsed by the moon, is known by the situation of the place within the penumbra, or its distance from the centre of the penumbra. And the phasis of the eclipse, as seen from any place Z , upon the disk, will be found thus, for any time. Find the centre of the shadow for that time, as suppose at H . Describe about H , a circle, whose radius is the moon's radius, and about Z , a circle with the sun's radius. Then the part cut off the sun's circle will be the part obscured.

SECT. VIII.—REMARKS ON ECLIPSES IN GENERAL.

754. In eclipses of the moon, even when she is near the centre of the earth's shadow, her body is still visible, and appears of a tarnished copper color. This seems to be occasioned by the rays of light which come from the sun, and which, passing near the earth, are inflected from their rectilinear course by our atmosphere; so that they enter the earth's conical shadow, thus producing that faint illumination on the surface of the moon, which some have supposed to be her own native light; but there seems to be no just ground for such a conjecture.

755. In most solar eclipses, the moon's disk is covered with a faint light, which is attributed to the reflection of the light from the illuminated part of the earth; and in total eclipses, the moon's limb is seen surrounded by a pale circle of light: which some astronomers consider as an indication of a lunar atmosphere, but others as the atmosphere of the sun; because it is observed to move equally with the sun, but not with the moon.

756. Eclipses have in all ages greatly attracted the attention of mankind. The ignorant and superstitious have viewed them with terror, and in former ages they were often considered as the forerunners of national calamities. The Chinese, even at the present day, upon their appearance, perform the most absurd and superstitious ceremonies, although they are so far acquainted with their nature, as to be able to predict them. See CHINA. But true philosophy has taught us, that

ASTRONOMY

GRAND ORRERY

made for King GEORGE I.

MR FERGUSON'S ORRERY

instead of these appearances being portentous of evil to mankind, they may, by proper observations upon them, be made of great advantage to the sciences, and to some of the arts of life.

757. We have already shewn, that, by eclipses of the moon, the earth is demonstrated to be a globular figure. The longitudes of places on the earth are also determined by observations on solar and lunar eclipses; as will appear by consulting the articles GEOGRAPHY, LONGITUDE, NAVIGATION, &c. Eclipses are also of great importance in CHRONOLOGY, (which see), as by them we are enabled to determine exactly the time when events recorded in history happened.

758. From the observations made upon the ancient eclipses, it appears that the period of the moon is now shorter, and consequently that her distance from the earth is now less, than in former ages; and this has been considered as an argument against those who assert, that the world may have existed from eternity; for it was hence inferred, that the moon moves in a resisting medium, and therefore that her motion must by degrees be all destroyed, in which case she must at last come to the earth. But M. de La Place has shewn, that this acceleration of the moon's period is a necessary consequence of universal gravitation, and that it arises from the action of the planets upon the moon. He has also shewn that this acceleration will go on, till it arrive at a certain limit, when it will be changed into a retardation; or in other words, that there are two limits, between which the lunar period fluctuates, but neither of which it can pass.

759. M. de La Grange has also discovered, that all the seeming irregularities in the motions of our system are periodical; so that although the obliquity of the ecliptic, the eccentricities of the planetary orbits, the precession of the equinoxes, the length of the year, &c. may change, yet these changes will not pass certain limits, and after stated periods, they will return precisely to what they had formerly been. Some of these periods, however, may be very long. The acceleration of the moon, for example, has been going on from the earliest ages of astronomy to the present day.

760. We cannot close this section, without observing, that eclipses happen very frequently to all the satellites of Jupiter; and, as they are of great service in determining the longitude of places on the earth, astronomers have been at pains to calculate tables for the eclipses of these satellites by their primary; for the satellites themselves have never been observed to eclipse one another. But this falls more properly to be considered under the articles GEOGRAPHY, and LONGITUDE, to which the reader is therefore referred.

761. The primary planets would also eclipse one another, were it not for their great distances; but, as the comets are not subject to the same laws with the planets, it is possible they may sometimes approach so near to the primary planets, as to cause an eclipse of the sun to those planets; and as the body of a comet bears a much larger proportion to the bulk of a primary planet than any secondary, it is plain, that a cometary eclipse would both be of much longer continuance, and attended with greater darkness, than

that occasioned by a secondary planet. If we suppose the primary planet and comet to be moving both the same way, the duration of such an eclipse would be prodigiously lengthened; and thus, instead of four minutes, the sun might be totally darkened to the inhabitants of certain places for as many hours: and, from this cause, some account for that prodigious darkness, which we sometimes read of in history, at times when no eclipse of the sun by the moon could possibly happen.

PART V.

ASTRONOMICAL MACHINERY AND INSTRUMENTS.

SECT. I.—DESCRIPTION OF THE ASTRONOMICAL MACHINERY INVENTED FOR ILLUSTRATING THE SCIENCE.

762. The Grand Orrery, a very magnificent machine, first made in this kingdom, by Mr. Rowley, for king George I. is represented in plate XII. fig. 1. The frame of it, which contains the wheel-work, &c. and regulates the whole machine, is made of ebony, and about four feet in diameter. Above the frame is a broad ring, supported with twelve pillars, which represents the plane of the ecliptic. Above the ecliptic, stand some of the principal circles of the sphere, viz. No. 10, are the two colures divided into degrees, and half degrees; No. 11, is one half of the equinoctial circle, making an angle of $23\frac{1}{2}^{\circ}$. The tropic of Cancer, and the arctic circle, are each fixed parallel, at their proper distance from the equinoctial. On the northern half of the ecliptic, is a brass semicircle, movable upon two points, fixed in \cap and \sphericalangle , representing the movable horizon to be put to any degree of latitude upon the north part of the meridian, and the whole machine may be set to any latitude, without disturbing any of the internal motions, by two strong hinges, (No. 13.) fixed to the bottom-frame, upon which the instrument moves, and a strong brass arch, having holes at every degree, through which a strong pin is put at every elevation. This arch, and the two hinges, support the whole machine, when it is lifted up, according to any latitude; and the arch, at other times, lies conveniently under the bottom frame.

763. The sun, (No. 1.) stands in the middle of the whole system, upon a wire, making an angle with the ecliptic, of about 82° . Next the sun is a small ball, (2), representing Mercury. Next to Mercury is Venus, (3), represented by a larger ball. The earth is represented (No. 4), by an ivory ball, having some circles and a map sketched upon it. The wire which supports the earth, makes an angle with the ecliptic, of $66\frac{1}{2}^{\circ}$, the inclination of the earth's axis to the ecliptic. Near the bottom of the earth's axis is a dial plate, (No. 9.) having an index, pointing to the hours of the day, as the earth turns round its axis. Round the earth is a ring supported by two small pillars, representing the orbit of the moon; and the divisions upon it answer to the moon's latitude. The motion of this ring represents the motion of the moon's orbit, according to that of the nodes. Within this ring is the moon, (No. 5), having a black cap or case, by

which its motion represents the phases of the moon, according to her age. Without the orbits of the earth and moon, is Mars, (No. 6.) The next in order to Mars is Jupiter, and his four moons, (No. 7.) Each of these moons is supported by a wire fixed in a socket, which turns about the pillar supporting Jupiter. These satellites may be turned by the hand to any position, and yet, when the machine is put into motion, they will all move in their proper times. The outermost of all is Saturn, his five moons, and his ring, (No. 8.) These moons are supported and contrived, similar to those of Jupiter.

764. The machine is put in motion, by turning a small winch, (No. 14); and the whole system is also moved by this winch, and by pulling out, and pushing in, a small cylindrical pin above the handle. When it is pushed, all the planets, both primary and secondary, will move according to their respective periods, by turning the handle. When it is drawn out, the motions of the satellites of Jupiter and Saturn will be stopped, while all the rest move without interruption. There is also a brass lamp, having two convex glasses, to be put in room of the sun; and also, a smaller earth and moon, made somewhat in proportion to their distance from each other, which may be put on at pleasure. The lamp turns round at the same time with the earth, and the glasses of it cast a strong light upon her; and when the smaller earth and moon are placed on, it will be easy to show when either of them will be eclipsed.

765. Mr. Ferguson's orrery, plate XII. fig. 2, shows the motions of the Sun, Mercury, Venus, Earth, and Moon; and occasionally the superior planets, Mars, Jupiter, and Saturn may be put on. Jupiter's four satellites are put round him in their proper times, by a small winch; and Saturn has his five satellites, and his ring, which keeps its parallelism round the sun; and by a lamp put in the sun's place, the ring shows all its various phases already described. In the centre, No. 1, represents the sun; No. 2, Mercury; No. 3, Venus; No. 4, the earth; No. 6, is a sidereal dial-plate under the earth; and No. 7, a solar dial-plate on the cover of the machine. The index of the former shows sidereal time, and of the latter, solar time.

766. The earth always keeps opposite to a moving index, (No. 10), which shews the sun's daily change of place, and also the days of the months. The earth is half covered with a black cap, for dividing the apparently enlightened half next the sun, from the other half, which, when turned away from him, is in the dark. The edge of the cap represents the circle bounding light and darkness, and shows at what time the sun rises and sets to all places throughout the year. The earth's axis inclines $23\frac{1}{2}^{\circ}$ from the axis of the ecliptic; by which means, the different lengths of days and nights, and the cause of the various seasons, are demonstrated to sight.

767. There is a broad horizon, to the upper side of which is fixed a meridian semicircle, in the north and south points. From the lower side of this thin horizontal plate stand out four small wires, to which is fixed a twilight-circle, eighteen degrees from the graduated side of the

horizon, all round. This horizon may be put upon the earth (when the cap is taken away), and rectified to the latitude of any place; and then by a small wire, called the solar ray, which may be put on, so as to proceed directly from the sun's centre towards the earth's, but to come no farther than almost to touch the horizon. The beginning of twilight, time of sun rising, with his amplitude, meridian altitude, time of setting, amplitude then, and end of twilight, are shown for every day of the year, at that place to which the horizon is rectified.

768. The moon, (No. 5.) exhibits all the phases already described. When the horizon is rectified to the latitude of any given place, the times of the moon's rising and setting, together with her amplitude, are shown to that place, as well as the sun's; and all the various phenomena of the harvest moon are made obvious to sight. The moon's orbit, (No. 9.) is inclined to the ecliptic, (No 11.) one half being above, and the other below it. The nodes, or points at 0 and 0, lie in the plane of the ecliptic, as before described, and shift backward, through all its sines and degrees, in $18\frac{1}{2}$ years.

769. The degrees of the moon's latitude, to the highest in N L, (north latitude,) and lowest at S L, (south latitude,) are engraven both ways from her nodes at 0 and 0; and, as the moon rises and falls in her orbit, according to its inclination, her latitude and distance from her nodes are shown for every day, having first rectified her orbit, so as to set the nodes to their proper places in the ecliptic; and then, as they come about, at different, and almost opposite times of the year, and then point towards the sun, all the eclipses may be shown for hundreds of years (without any new rectification), by turning the machinery backward, for time past, or forward for time to come.

770. At 17° distance from each node, on both sides, is engraved a small sun; and at 12° distance a small moon, which show the limits of solar and lunar eclipses; and when, at any change, the moon falls between either of these suns and the node, the sun will be eclipsed on the day pointed to by the annual index, (No. 10). And when at any full, the moon falls between either of the little moons and node, she will be eclipsed, and the annual index shows the day of that eclipse. There is a circle of $29\frac{1}{2}$ equal parts (No. 8) on the cover of the machine, on which an index shows the days of the moon's age. There is a jointed wire, of which, one end being put into a hole in the upright stem that holds the earth's cap, and the wire laid into a small forked piece which may be occasionally put upon Venus or Mercury, shows the direct and retrograde motions of these two planets, with their stationary times and places, as seen from the earth. The whole machinery is turned by a winch, (No. 12) and is so easily moved, that a clock might turn it, without any danger of stopping.

771. Mr. Jones's Planetarium, plate XI. fig. 1, represents in a general manner, by various parts of its machinery, all the motions and phenomena of the planetary system. This machine consists of, the Sun in the centre, with the planets, Mercury, Venus, the Earth and Moon,

Mars, Jupiter and his four moons, Saturn and his five moons; and to it is occasionally applied an extra long arm for the planet Herschel and his two moons. To the earth and moon is applied a frame C D, containing only four wheels and two pinions, which serve to preserve the earth's axis in its proper parallelism in its motion round the sun, and to give the moon her due revolution about the earth at the same time. These wheels are connected with the wheel-work in the round box below, and the whole is set in motion by the winch H. The arm M, which carries round the moon, points out on the plate, B, her age and phases for any situation in her orbit, and which accordingly are engraved thereon. In the same manner the arm points out her place in the ecliptic B, in signs and degrees, called her geocentric place. The moon's orbit is represented by the flat rim A'; the two joints of which, and upon which it turns, denoting her nodes. This orbit is made to incline to any desired angle. The earth of this instrument is usually made of a three inch or $1\frac{1}{2}$ globe, papered, &c. for the purpose; and by means of the terminating wire that goes over it, points out the changes of the seasons, and the different lengths of days and nights more conspicuously. This machine is also made to represent the Ptolemaic system, or such as is vulgarly received; which places the earth in the centre, and the planets and sun revolving about it. This very excellent instrument may justly be considered as the best devised piece of apparatus that has ever been contrived for the purpose.

772. The true causes of the solar and lunar eclipses are here very clearly seen; for by placing the lamp, fig. 5, plate XI., upon the centre, instead of the brass ball denoting the sun, and turning the winch until the moon comes into a right line between the centres of the lamp (or sun) and the earth, the shadow of the moon will fall upon the earth. On the other side, the moon passes (in the aforesaid case) through the shadow of the earth, and is by that means eclipsed. And the orbit A, fig. 1, is so movable on the two joints called nodes, that any person may easily represent the due position of the nodes and intermediate spaces of the moon's orbit; and thence show when there will, or will not be, an eclipse of either luminary, and what the quantity of each will be. While the moon is continuing to move round the earth, the lamp on the centre will so illuminate her, that all her phases, as new, dichotomised, gibbous, full, waning, &c. will be seen just as they appear in the heavens. All the same phases of the earth, as they appear at the moon, will also be exhibited. The satellites of Jupiter and Saturn are movable only by the hand; yet all their phenomena may be easily represented, excepting the true relative motions and distances.

773. The Trajectorium Lunare, fig. 8, plate XIII, is intended, by delineating the paths of the earth and moon, to show what sort of curves they make in the ethereal regions. S is the sun, and E the earth, whose centres are ninety-five inches distant from each other; every inch answering to 1,000,000 of miles. M is the moon, whose centre is $\frac{24}{100}$ parts of an inch from the

earth's in this machine, this being in just proportion to the moon's distance from the earth. AA is a bar of wood, to be moved by hand round the axis *g*, which is fixed in the wheel Y. The circumference of this wheel is to the circumference of the small wheel L, below the other end of the bar, as $365\frac{1}{4}$ days to $29\frac{1}{2}$, or as a year is to a lunation. The wheels are grooved round their edges, and in the grooves is the catgut string GG, crossing between the wheels at X. On the axis of the wheel L, is the index F, in which is fixed the moon's axis M, for carrying her round the earth E, fixed on the axis of the wheel L in the time that the index goes round a circle of $29\frac{1}{2}$ equal parts, which are the days of the moon's age. The wheel Y has the months and days of the year all round its limb; and in the bar AA is fixed the index *l*, which points out the days of the months answering to the days of the moon's age, shewn by the index F, in the circle of $29\frac{1}{2}$ equal parts at the other end of the bar. On the axis of the wheel is put the piece D, below the cock C, in which this axis turns round; and in D are put the pencils *e* and *m*, directly under the earth C and moon M; so that *m* is carried round *e* as M is round E.

774. Lay the machine on an even floor, pressing gently on the wheel Y, to cause its spiked feet (of which two appear at P, the third being supposed to be hid from the sight by the wheel) to enter a little into the floor to secure the wheel from turning. Then lay a paper about four feet long under the pencils *e* and *m*, cross-ways to the bar; which done, move the bar slowly round the axis *g* of the wheel Y; and as the earth E goes round the sun S, the moon M will go round the earth with a duly proportioned velocity; and the friction wheel W, running on the floor, will keep the bar from bearing too heavily on the pencils *e* and *m*, which will delineate the paths of the earth and moon. As the index I points out the days of the months, the index F shows the moon's age on these days, in the circle of $29\frac{1}{2}$ equal parts. And, as this last index points to the different days in its circle, the like numeral figures may be set to those parts of the curves of the earth's and moon's paths, where the pencils *e* and *m* are at those times respectively, to shew the places of the earth and moon. If the pencil *e* be pushed a very little off, as if from the pencil *m*, to about $\frac{1}{10}$ part of their distance, and the pencil *m* pushed as much towards *e* to bring them to the same distances again, though not to the same points of space; then *m* goes round *e*, *e* will go as it were round the centre of gravity between the earth *e* and moon *m*; but this motion will not sensibly alter the figure of the earth's path or that of the moon's.

775. If a pin, as *p*, be put through the pencil *m*, with its head towards that of the pin *g*, in the pencil *e*, its head will always keep thereto as *m* goes round *e*, or as the same side of the moon is still obverted to the earth. But the pin *p*, which may be considered as an equatorial diameter of the moon, will turn quite round the point *m*, making all possible angles with the line of its progress, or line of the moon's path. This is

an ocular proof of the moon's turning round her axis.

SECT. II. OF THE PRINCIPAL INSTRUMENTS USED FOR MAKING ASTRONOMICAL OBSERVATIONS.

776. In practical astronomy it is necessary to have a place conveniently situated, and suitably furnished with proper astronomical instruments. It should have an uninterrupted view from the zenith down to, or even below, the horizon, at least towards its cardinal points. For this purpose that part of the roof in particular which lies in the direction of the meridian, should have moveable covers, which may easily be moved and put on again; by which means an instrument may be directed to any point of the heavens between the horizon and zenith, either northward or southward. This place, called an observatory, should contain some, if not all, of the following instruments:

777. 1. A pendulum clock for showing equal time. This should show time in hours, minutes, and seconds; and with which the observer, by hearing the beats of the pendulum, may count them by his ear, while his eye is employed on the motion of the celestial object he is observing. Just before the object arrives at the position described, the observer should look on the clock and mark the time, suppose it 6h. 15min. 25sec.; then saying, 25, 26, 27, 28, &c. responsive to the beat of the pendulum, till he sees through the instrument the object arrived at the position expected; which suppose to happen when he says 38, he then writes down 9h. 15m. 38sec. for the time of observation, annexing the year and the day of the month.

778. 2. An achromatic refracting telescope, or a reflecting one, of two feet at least in length, for observing particular phenomena. See the description under OPTICS.

779. 3. A micrometer, for measuring small angular distances. See MICROMETER.

780. Astronomical quadrants, both mural and portable, for observing meridian and other altitudes of the bodies.

781. 4. The mural quadrant, so called from murus a wall: it is in the form of a quarter of a circle, contained under two radii at right angles to one another, and an arch equal to one fourth part of the circumference of the circle. This is the most useful and valuable of all the astronomical instruments; and, as it is sometimes fixed to the side of a stone or brick wall, and the plane of it erected exactly in the plane of the meridian, it receives the name of mural quadrant. Tycho Brahe was the first person who applied this arch to a wall; and Flamsteed the first in England who, with indefatigable pains, fixed one up in the royal observatory at Greenwich.

782. Mural quadrants have usually been made from five to eight feet radius. Fig. 1, plate XIII. represents the instrument fixed to the wall. The frame is formed of flat bars, and strengthened by edge bars, fixed underneath perpendicular to them. The radii HB , AA , being divided each into four equal parts, serve to find the points D and E , by which the quadrant is freely suspended on its iron supports, that are fastened

in the wall. One of the supports, E , is represented separately in e on one side of the quadrant. It is moveable by means of a long slender rod EE or e, f , which goes into a hollow screw in order to restore the instrument to its situation when it is discovered to be a little deranged. This may be known by the very fine perpendicular thread HA , which ought always to coincide with the same point A of the limb, and carefully examined to be so by a small magnifying telescope at every observation.

783. In order to prevent the unsteadiness of so great a machine, there should be placed behind the limb four copper ears with double cocks, I , K , I , K . There are others along the radii HA and HB ; each of these cocks contains two screws, into which is fastened the ears that are fixed behind the quadrant. Over the wall or stone which supports the instrument, and at the same height as the centre, is placed horizontally the axis PO , which is perpendicular to the plane of the instrument, and which would pass through the centre if it was continued. This axis turns on two pivots P . On this axis is fixed at right angles another branch, ON , loaded at its extremity with a weight, N , capable of equipoising with its weight that of the telescope LM ; whilst the axis, by its extremity nearest the quadrant, carries the wooden frame PRM , which is fastened to the telescope in M . The counterpoise takes off from the observer the weight of the telescope when he raises it, and hinders him from either forcing or straining the instrument. The lower extremity, V , of the telescope, is furnished with two small wheels, which take the limb of the quadrant on its two sides. The telescope hardly bears any more upon the limb than the small friction of these two wheels; which renders its motion so extremely easy and pleasant, that by giving it with the hand only a small motion, the telescope will run of itself over a great part of the limb, balanced by the counterpoise N .

784. When the telescope is to be stopped at a certain position, the copper hand T is to be made use of, which embraces the limb and springs at the bottom. It is fixed by a setting screw, which fastens it to the limb. Then, in turning the regulating screw, the telescope will be advanced; which is continued until the star, or other object whose altitude is observing, be on the horizontal fine thread in the telescope. Then on the plate X , supporting the telescope, and carrying a vernier or nonius, will be seen the number of degrees and minutes, and even quarter of minutes, that the angular height of the object observed is equal to. The remainder is easily estimated within two or three seconds nearly.

785. There are several methods of subdividing the divisions of a mural quadrant, which are usually from five or ten minutes each; but that which is most commonly adopted is by the vernier or nonius, the invention of Peter Vernier, a Frenchman. This vernier consists of a piece of copper or brass, $CDA B$, fig. 6, which is a small portion of X , fig. 1, represented separately. The length, CD , is divided into twenty equal parts, and placed contiguously on a portion of the division of the limb of the quadrant,

Equatorial or Observatory

containing twenty-one divisions, and thereby dividing their length into twenty equal parts. Thus the first division of the vernier piece marked 15, beginning at the point D, is a little backward, or to the left of the first division of the limb, equal to $15''$.

786. The second division of the vernier, is to the left of the second division of the limb double of the first difference, or $30''$; and so on to the twentieth, and last division on the left of the vernier piece; where the twenty differences being accumulated, each of the twentieth part of the division of the limb, this last division will be found to agree exactly with the twenty-first division of the limb of the quadrant. The index must be pushed the twentieth part of a division, or $15''$ to the right; to make the second division on the vernier coincide with one of the divisions of the limb, in like manner in moving two 20ths, or $30''$, we must look at the second division of the index, and there will be a coincidence with a division of the limb. Thus the beginning, D, of the vernier, which is always the line of reckoning, has advanced two divisions, or $30''$ to the right, when the second division, marked 30 on the vernier, is seen to correspond exactly with one of the lines of the quadrant.

787. The plate of copper which carries the telescope, is placed on the side of the quadrant, and carries two verniers. The outer line CD divides five minutes into twenty parts, or $15''$ each. The interior line AB answers to the parts of another division, not having 90° , but 96 parts of the quadrant. It is usually adopted by English astronomers, on account of the facility of its subdivisions. Each of the 96 portions of the quadrant is equivalent to $56' 15''$ of the usual divisions. It is divided on the limb into sixteen parts, and the arch of the vernier AB contains twenty-five of these divisions; and being divided itself into twenty-four, immediately give parts, the value of each of which is $8' 47\frac{1}{3}''$.

788. 6. The portable astronomical quadrant is generally made from twelve to twenty-three inches. Fig. 2, plate XIII. represents one of brass, and strongly framed together by crossed perpendicular bars. The arch A C, and telescope E F, are divided and constructed in a similar manner to the mural quadrant, but generally without the division of ninety-six parts. The counterpoise to the telescope T is represented at P, and also another counterpoise to the quadrant itself at P. The quadrant is fixed to a long axis, which goes into the pillar K R. Upon this axis is fixed an index, which points to, and subdivides by a vernier, the divisions of the azimuth circle, K. This azimuth circle is extremely useful for taking the azimuth of a celestial body, at the time its altitude is observed. The upper end of the axis is firmly connected with the adjusting frame G H; and the pillar is supported on the crossed feet at the bottom of the pillar K R, with the adjusting screws *a b c d*.

789. When the instrument is erected for observation, it is necessary that two adjustments be very accurately made; one, that the place or surface of the instrument be truly perpendicular to the horizon; the other, that the line supposed to be drawn from the centre to the first line of the

limb, be truly on a level or parallel with the horizon. The first of these particulars is done by means of the thread and plummet *p*; the thread of which is usually of very fine silver wire, and is placed opposite to a mark made upon the end of the limb of the instrument. The four screws at the foot *a b c d*, are to be turned until a perfect coincidence is observed of the thread upon the mark, which is accurately observed by means of a small telescope T, that fits to the limb. The other adjustment is effected by means of the spirit-level L, which applies on the frame G H, and the small screws turned as before until the bubble of air in the level settles in the middle of the tube. The dotted tube E B is a kind of prover to the instrument; for, observing at what mark the centre of it appears against, or, by putting up a mark against it, it will at any time discover if the instrument has been displaced. The screw S, at the index, is the regulating or adjusting screw, to move the telescope and index, during the observation, with the utmost nicety.

SECT. VII.—THE MURAL CIRCLE.

790. Valuable as have been the services which the astronomical quadrant has rendered to astronomical science, its use, in modern times, has been altogether superseded by the mural circle, of which we shall now give the description and use:—

791. The circle, with its attached telescope, is made to revolve by means of a horizontal axis, which works in collars fixed in the stone wall. The plane of the circle, see plate X. fig. 3, is parallel to the wall, but the graduations are made on the outer rim of the instrument, which rim is perpendicular to the wall.

792. These graduations are viewed and read off by six microscopes fixed to the wall, one of which microscopes is represented at A, and the places of the five others (precisely similar to the former) are marked by the letters B, C, D, E, F. The microscopes are distant from each other sixty degrees, or so placed as nearly as can be by the instrument maker.

793. The rim is divided into equal parts of five minutes each, and the readings off to a less number of minutes, and to single seconds, are effected by the micrometer microscopes, A, B, &c. the construction of which is as follows: The microscope A, or micrometer microscope A, is directed, as it is shown in the figure, to the rim on which the graduations are made. Consider the object to the microscope to be one graduation of the instrument, or the space occupied by five minutes. The image of this space will be formed in the conjugate focus of the object glass, and will be seen distinctly through the eye-glass of the microscope, when the above-mentioned image is in its focus. In this latter focus (the focus of the eye-glass) are placed a thin indented slip of metal, and a wire capable of being moved in a parallel direction from one mark of division to another by means of a screw. The revolutions of the screw, and parts of its revolution, are noted by means of a screw-head and graduated plate. Now, it is desirable, for the more convenient noting of the

results of observations, that by the five revolutions of the screw, the wire should be translated through the space occupied by five minutes; in which case one revolution would answer to one minute, and one-sixtieth to a second. The mode of effecting this may be thus explained:—

794. Suppose the object-glass of the microscope being at a certain distance from the graduated rim, and there being distinct vision, that the moveable wire appears to be translated through the five minutes by five revolutions and a half of the screw. In such case the image of the five minutes is too small. It will be increased by moving the object-glass towards the graduated rim; the eye-glass, with its wire, &c. being adjusted, by a separate movement, to distinct vision. A second trial must now be made, to ascertain whether five revolutions of the screw are equal or not to the translation of the wire over the image of five minutes of the divided limb. If there is not an equality, the adjustments must be repeated till there be an exact correspondence, as considerable trouble is thereby saved in reducing the graduations of the screw-head to minutes and seconds. If the microscope of the micrometer were allowed to remain in its first state, then, since 5.5 revolutions = $5'$, one revolution would equal $50.454''$ &c.

795. But, whatever be the value of a revolution, the uses of the moveable wire and indented slip of brass are the same. A star is observed on the centre of the cross-wire of the telescope; and on looking through the microscope, the index, or slip of brass, occupies, probably, a place between two graduations. The wire moved from the index, either to the graduation above or below it, measures the distance of the index from that graduation by the revolutions of the screw-head. For convenience, each tooth of the indented brass answers to one minute, so that if the wire is moved from the index post, two teeth, and the index of the screw-head points to 37, then $2' 37''$ are to be added to, or subtracted from, the degrees and minutes which are read off by the eye without the aid of the micrometer. In every observation all the six microscopes are used, to diminish the errors of division, and the effects of partial expansion.

796. In reading off at the several microscopes, we need only attend to the seconds. For, suppose a star to be in the pole, and the telescope directed to it, the whole circle must be turned round in the direction from B towards C, D, &c.; and the end of the telescope, instead of being directed, as in the figure, to a point in the south, between B and C, will be directed to a point between D and A. If (the telescope being directed to the pole) the reading off at the micrometer A were $0^{\circ} 0' 0''$, the index error would be 0. If the other microscopes, F, E, B, &c. were placed exactly at equal distances, the reading off at them would be 60° , 120° , 180° , 240° , 360° . This, however, is not likely to take place, the index error of each will probably be of some magnitude. The reading off at A, for instance, instead of being $0^{\circ} 0' 0''$, may be $+ 3''$, $+ 10''$, $+ 7''$; and in the same way the reading off at the other microscopes, from their not being placed at equal distances, or from inequality of

graduation, partial expansion, or from all these causes conjoined, may be $60^{\circ} \pm 4''$, $60^{\circ} \pm 6''$, $120^{\circ} + 9''$, $120^{\circ} + 1''$, &c.

799. Suppose that, independently of the degrees and minutes, the seconds at the six microscopes were $+ 5''$, $+ 7''$, $+ 4'' + 12'' + 8''$, $+ 9''$; then these are the several index errors; and if the polar distance of an observed star were read off only at one microscope, the index error belonging to that microscope must be applied to the polar distance so read off. Thus, if only the microscope B were used, whose index error is $+ 12''$, and the north polar distance of β Ursa Minores, were read off, $195^{\circ} 4' 46''$, then deducting 180° for the position of the microscope, and $12''$ for the index error, we should have the north polar distance of the star = $50^{\circ} 4' 34''$.

800. If all the six microscopes are used, the mean index error, or one-sixth of the several index errors, is applied to the result of the several readings.

801. The same illustration would serve if we suppose the telescope directed to a star whose polar distance is previously known. If, for example, we knew that the north polar distance of Polaris was $1^{\circ} 41' 41.3''$; then if the micrometer A, marked $1^{\circ} 41' 48.5''$, we should know that its index error was $7.2''$; and the equation to be applied to its observed north polar distance at that microscope — 7.2 . In like manner we should know from the same star the index errors of the other microscopes, and thence the mean index error.

802. That the results from this instrument do not depend on the accurate positions of the microscopes, may be easily shown. Suppose the telescope directed to the pole, and that the seconds indicated by the micrometer A be $7''$, let B indicate $b + 23''$; C, $c + 4$; D, $d + 5$; E, $e + 9$, and F, $f + 15$; b, c, d , &c. denoting the degrees and minutes. Let X be the north polar distance of any star (Capella, for example, X being = $44^{\circ} 12' 16''$), and let the number of seconds in X be 16; so that, y being the degrees and minutes $x = y + 16''$; then the instrument being directed to Capella (and consequently turned through an angle X), and the errors of division, expansion, and uncertainties in reading off not being considered, the seconds at which it will stand will be 23, B, 39; C, 20; D, 21; E, 25, and F, 31; one-sixth of the sum of which is $26.5''$, whence the north polar distance of Capella by the instrument, is $Y + 26.5'' = 44^{\circ} 12' 26.5''$; and consequently the mean index error $y + 26.5'' - x = y + 26.5'' - y + 16'' = 10.5''$.

803. The index error may be found in the same way by any other star, since x may be any angle; and if the catalogues were exact, and the instrument perfect, the same index error would result from all stars. If, for instance, the seconds in x , instead of $16''$ were $36''$, we should still have the same index error $10.5''$. But in practice, the index error will be found different with different stars, both on account of the imperfection of the catalogues, the inaccuracy of graduation, and other defects in the instrument. The index error, therefore, is found from observations on a

great number of stars, and the mean of the whole of the errors so found, is considered as the general mean index error.

804. For the purpose of lessening the errors of division, the telescope can be shifted to different parts of the circle, so that instead of the microscope A, nearly coinciding with O, when the telescope is pointed to the pole, it may point nearly to 10° , 20° , 30° , or any other degree of the circle. In this case the index error in seconds, found as above, added to the degrees and minutes read off by the eye, is the index error of the microscope.

805. The mural circle, like the transit instrument, requires three adjustments, 1. Its axis must be made horizontal. 2. Its line of collimation must be made perpendicular to the horizontal axis. 3. The line of collimation must be made to move in the plane of the meridian.

806. The method of making the first adjustment is the same as that for making the like adjustment in the transit instrument; and as the two instruments are commonly used in conjunction, we may use the transit instrument for bringing the plane of the circle and its telescope into the plane of the meridian. When a star is on the meridional wire of the transit instrument, move the mural circle, so that the star may be also on its middle wire. Observe, by the transit instrument, when a star is or near the zenith crosses the meridian, and if it is also at the same time on the middle vertical wire of the telescope of the mural circle, its line of collimation is rightly adjusted. If a difference exists, adjust till an exact agreement takes place.

807. The great difficulties attending the verification of the line of collimation in the mural circle, will always prevent its becoming a good transit instrument; though, in this respect, it acts better than the telescope of the mural quadrant, which slides along the limb of the quadrant, whose plane cannot be made wholly on the plane of the meridian.

808. The mural circle is evidently sufficient to determine to the extent of 180° , the differences of the declinations of stars south and north of the zenith of the observer. There must be two quadrants to effect the same object; and besides this advantage (that of a single instrument), the circle is better balanced, and its six microscopes, which are firmly fixed in a stone wall, together with the power of changing the position of the telescope, must, when we take the mean results of a great number of observations, in a great measure do away the errors of division or partial expansion.

809. The direct and special office of the mural circle is to determine the meridional angular distances of stars. But we may extend the principle of its uses, and view the image of the pole star, by reflection, from a basin of quicksilver, and we thence obtain the angular distance between the star and its image, which is twice the elevation of the star above the horizon. Hence its zenith distance becomes known, and the zenith distances of other stars are consequently readily given by the instrument. The circle in this application combines in itself the properties of the mural quadrant and zenith sector. It was

first applied by the present astronomer royal, and it is one of the many improvements on practical astronomy for which the world is indebted to that eminent, active, and unassuming astronomer.

810. The preceding is a concise description of the circle which Troughton fixed at the Royal Observatory. Some trifling differences between the results given by it and other instruments, lately induced government to have another made by Jones, which is now fixed to the west wall, five feet from the other circle. The agreement between them is almost perfect.

811. Dr. Brinkley of Dublin has a circle, and a very admirable one, which moves round a pillar, or azimuth; and consequently, in two days it determines double the zenith distance of any celestial object. He employs only three microscopes in reading off; but the principle of reading is the same as that which we have above described; and a person who attentively considers what we have said on the subject of the Greenwich circle, will have no difficulty in comprehending the method of using the Dublin one.

812. 8. The Astronomical or Equatorial Sector, is an instrument for finding the difference, in right ascension and declination, between two objects; the distance of which is too great to be observed by the micrometer, and was invented by Graham. Let A B, plate XIII. fig. 4, represent an arch of a circle containing ten or twelve degrees well divided, having a strong plate C D for its radius, fixed to the middle of the arch at D: let this radius be applied to the side of an axis H F I, and be movable about a joint fixed to it at F, so that the plane of the sector may be always parallel to the axis H I; which being parallel to the axis of the earth, the plane of the sector will always be parallel to the plane of some hour circle. Let a telescope C E be movable about the centre C, of the arch A B, from one end of it to the other, by turning a screw at G; and let the line of sight be parallel to the plane of the sector. Now, by turning the whole instrument about the axis H I, till the plane of it be successively directed, first to one of the stars and then to another, it is easy to move the sector about the joint F, into such a position, that the arch A B, when fixed, shall take in both the stars in their passage, by the plane of it, provided the difference of their declinations does not exceed the arch A B. Then, having fixed the plane of the sector a little to the westward of both the stars, move the telescope C E by the screw G; and observe by a clock the time of each transit over the cross hairs, and also the degree and minutes upon the arch A B, cut by the index at each transit; then in the difference of the arches, the difference of the declinations, and by the difference of ψ times, we have the difference of the right ascensions of the stars.

813. The dimensions of this instrument are these: The length of the telescope, or the radius of the sector, is $2\frac{1}{2}$ feet; the breadth of the radius, near the end C, is $1\frac{1}{2}$ inch; and at the end D, two inches. The breadth of the limb, A B, is $1\frac{1}{2}$ inch; and its length six inches, containing ten degrees, divided into quarters, and

numbered from either end to the other. The telescope carries a nonius or subdividing plate, whose length, being equal to sixteen quarters of a degree, is divided into fifteen equal parts; which, in effect, divides the limb into minutes, and by estimation, into smaller parts. The length of the square axis, HIF , is eighteen inches, and of the part III twelve inches; and its thickness is about a quarter of an inch: the diameters of the circles are each five inches: the thickness of the plates, and the other measures, may be taken at the direction of a workman.

814. This instrument may be rectified, for making observations, in this manner: By placing the intersection of the cross hairs at the same distance from the plane of the sector, as the centre of the object-glass, the plane described by the line of sight, during the circular motion of the telescope upon the limb, will be sufficiently true, or free from conical curvity; which may be examined, by suspending a long plumb-line at a convenient distance from the instrument; and, by fixing the plane of the sector in a vertical position, and then by observing, while the telescope is moved by the screw along the limb, whether the cross hairs appear to move along the plumb-line.

815. The axis, hfo , fig. 5, may be elevated, nearly parallel to the axis of the earth, by means of a small common quadrant; and its error may be corrected, by making the line of sight follow the circular motion of any of the circumpolar stars, while the whole instrument is moved about its axis, hfo , the telescope being fixed to the limb; for this purpose, let the telescope kl be directed to the star a , when it passes over the highest point of its diurnal circle, and let the division cut by the nonius be then noted: then, after twelve hours, when the star comes to the lowest point of its circle, having turned the instrument half round its axis, to bring the telescope into the position, mn ; if the cross hairs cover the same star supposed at b , the elevation of the axis, hfo , is exactly right; but, if it be necessary to move the telescope into the position uv , in order to point to the star at c , the arch mu , which measures the angle mfo or bfc , will be known; and then the axis hfo must be depressed half the quantity of this given angle, if the star passed below b , or must be raised so much higher, if above it; and then the trial must be repeated, till the true elevation of the axis be obtained. By making the like observations upon the same star on each side the pole, in the six o'clock hour circle, the error of the axis, toward the east or west, may also be found and corrected, till the cross hairs follow the star quite round the pole: for, supposing $apbc$ to be an arch of the meridian (or in the secondary practice of the six o'clock hour circle), make the angle afp equal to half an angle afc , and the line fp will point to the pole; and the angle ofp , which is the error of the axis, will be equal to half the angle bfc , or mfn , found by the observation; because the difference of the two angles afb , afc , is double the difference of their halves afp and afp . Unless the star be near the pole, allowance must be made for refractions.

816. 9. The transit instrument is used for observing objects as they pass over the meridian, and consists of a telescope fixed at right angles to an horizontal axis, so supported that what is called the line of collimation, or line of sight of the telescope, may move in the plane of the meridian.

817. Let AD , plate X. fig. 1, represent a telescope fixed, as it is represented in the figure, to an horizontal axis formed of two cones. The two small ends of these cones are ground into two perfectly equal cylinders; which cylindrical ends are called pivots. These pivots rest on two angular bearings, in form like the upper part of a Y , and denominated Y 's. The Y 's are placed in two dove-tailed brass grooves, fastened in two stone pillars, E and W , so erected as to be perfectly steady. One of the grooves is horizontal, the other vertical; so that, by means of screws, one end of the axis may be pushed a little forwards or backwards, and the other end may be either slightly depressed or elevated. Which two small movements are necessary, as it will be soon explained, for two adjustments of the telescope.

818. Let E be called the eastern pillar, W the western. On the eastern end of the axis is fixed (so that it revolves with the axis) an index n , the upper part of which, when the telescope revolves, nearly slides along the graduated face of a circle; attached, as it is shown in the figure, to the eastern pillar. The use of this part of the apparatus is to adjust the telescope to the zenith, or polar distance (for the one is as easily done as the other) of a star, the transit of which is to be observed. Thus, suppose the index of n to be at o (in the upper part of the circle) when the telescope is horizontal; by elevating the telescope, the index of n is moved downwards. Suppose the position to be that represented in the figure, then the number of degrees between o , and what the index of n marks, is the altitude of the telescope; or we may so graduate the circle, that the index shall mark the telescope's zenith distance; or, if we make the o , the beginning of the graduation, to belong to that position of the telescope in which it is directed to the pole, the number of degrees, &c. between o and any other position of the index, will mark either the telescope's polar distance, or if we please, may be made to mark the telescope's declination; the telescope in all these cases being supposed to move in the plane of the meridian.

819. There are several other parts and contrivances belonging to the instrument not shown in the figure; for instance, one of the cones is hollowed; and, opposite the orifice, there is placed in the pillar a lamp, which, throwing its light on a plane speculum, placed in the axis of the telescope, and inclined at an angle of 45° , illuminates the cross wires. It is usual, also, in large transits, to have counterpoises, by which the pressure of the pivots of the axis on the Y 's is relieved. We will now explain the three principal adjustments of the transit.

820. 1. To make the axis on which the telescope moves, horizontal.

821. 2. To make the line of collimation move in a great vertical circle; or, which is the same

thing, to make it perpendicular to the horizontal axis.

822. 3. To make it move in that vertical circle which is the meridian.

823. The first adjustment is effected by means of a level; the figure A is intended to represent the level L, as hanging by means of its upright arms (bent, however, in their upper extremities) on the two pivots of the axis. The principle, however, and mode of rendering any axis horizontal, by means of a level, may be best explained by the subjoined figure.

824. In plate X, fig. 2, the spirit-level (including in that term the brass tube that partly envelops it, the horizontal bar to which it is affixed, and the two vertical arms by which it is hung on any cylinder or rod) is represented as hanging on a straight cylinder $a b$, the end towards a lying on a crotchet, which is capable of being raised or lowered by a screw B. The end A of the tube A D, which contains the level, is also capable of being lowered or raised by means of a screw at A, as is shown in the figure.

825. If $a b$ were horizontal, and the tube of the spirit-level were parallel to $a b$, then the bubble would occupy the middle, or the two extremities of the bubble would be equidistant from the centre, and would be, for instance, at f and c . The same thing would happen if the level were reversed, that is, if it were taken off the rod, turned round, and again hung on; so that d in the second position, should occupy the place that A did in the first, or should be to the right hand. But if $a b$, should not be horizontal, the above circumstances cannot take place. Suppose the end a to be lower than the end b , then if the level should not be parallel to $a b$, the bubble might still stand in the middle, by the end at A being, by a certain quantity, higher than the end at B. But on reversing the level the bubble cannot occupy its middle; since then, the lower part of the rod $a b$, and the lower part of the level, would both be situated at the right hand. The bubble, however, may not stand in the middle from two causes, the want of horizontality in $a b$, and the want of parallelism to it in the tube contained between A D.

826. If the level were parallel to $a b$, and the extremity of the bubble, instead of being at e , should be at h , on reversing the level, the other extremity of the bubble (which, by the reversion, would be towards a) would be at h ; $f k$ being equal to $e h$. But suppose this is found not to be the case, and that the extremity of the bubble, on reversing the level, is at n , then the circumstance of the bubble not standing at the two points e and f , cannot arise solely from the end a being higher than b ; but the level cannot be parallel to $a b$; and in the case we have put, the end at A must be lower than the end at D, when the level then is in the second or the reversed position; so elevate the end at A, by means of the screw A, that the extremity of the bubble shall descend from n , and occupy a place intermediate to n and k , and then the level is made parallel to $a b$: this is the first adjustment. Next, by means of the screw B, so depress the end, a that the extremities of the bubble shall be (as they ought to be. $e f$ being the length of the bubble) at

e and f ; then is $a b$ adjusted or made horizontal; this second adjustment completes the operation.

827. In the preceding reasonings, $a b$ has been considered (the whole of it) as cylindrical. But this is not necessary: it is sufficient if its extremities at a and b (the pivots), on which the level is hung, be equal cylinders, the axis of which lie in the same straight line. The intermediate parts of the axis of the transit between the pivots, may be of any form: they may be formed, as they generally are, of two cones. The preceding process then will render the axis of the transit horizontal; the level, whether in its primary or in its reversed position, being supposed to be hung on the equally cylindrical pivots.

828. The axis being now horizontal, the next operation is to make the line of collimation describe a great vertical circle, or, which is now the same thing, to make the line of collimation perpendicular to the axis of the transit. The telescope A D is furnished, like the telescope of the quadrant, with a system of cross-wires placed in the principal focus of the object-glass. Suppose the wires so placed, that the line of collimation is perpendicular to the axis of the transit. If then a small and well-defined object be bisected by the centre of the cross-wires, it will still be bisected when the transit is lifted off its angular bearings, reversed and directed to the object; that is, if the end of the axis carrying the index n , which is placed on the eastern Y, should be placed on the western. Let now the wires be deranged, so that their intersection is moved, not, as in the former case, in the plane of the meridian, but in a direction perpendicular to that plane, and suppose it moved a little towards the east. In this case, the object before bisected is no longer so, but will be seen in the field of view a little to the west of the present centre of the cross-wires. Reverse the telescope, then the centre will be towards the west, and the original object will be seen a little to the east of the centre: as much towards the east as it was before towards the west. If, therefore, there should be two objects or marks (on the horizon, for instance,) bisected by the centre of the wires in the two positions of the transit, the correction or adjustment of the line of collimation would consist in moving the centre of the cross-wires half-way towards that object which is not on the centre.

829. But the moving the centre of the cross-wires half-way towards an object, is a matter of guess, and not of certainty. In order to ascertain whether, in moving the centre, we have adjusted it rightly, we may avail ourselves of that angular bearing, or Y, which, by means of an horizontal groove and screw, we can move, together with the pivot of the axis, in azimuth. So move these then, that the object to which we have already made the centre to approach half-way, may be exactly bisected by that centre. Reverse the transit, and the object and centre are either coincident, or very nearly so. If the latter be the case, again by their proper motion, move the centre of the wires half-way towards the object, and move it the other half-way by the screw that acts on the axis. Reverse the instru-

ment, and again, if it be necessary, repeat the above operations.

830. By these means, after a few trials, we are sure of making the line of collimation, or axis of vision, perpendicular to the axis of the transit; and when that is effected, the cross-wires are no longer to be meddled with, although we must continue to use the above horizontal movement of the axis, for the purpose of placing the line of collimation in the plane of the meridian. That line now moves in a vertical circle, and produced passes through the zenith: it is farther necessary to make it pass through the pole.

831. The transit instrument is supported between two fixed pillars. It must be supposed to be nearly in the meridian, and to need only some slight adjustments to place it there exactly. It would be easy to effect this, were the pole-star exactly in the pole; for, then, it would be only requisite to bisect that star by the middle vertical cross-wire. But the pole-star being, in fact, a circumpolar one, we must compute, by means of existing tables and observations, the time of its transit; and, at that computed time, bisect the star by the middle vertical wire. By these methods we may place the transit very nearly in the plane of the meridian.

832. We will now show how to place it there more exactly by means either of the polar, or of any other circumpolar star.

833. The axis being horizontal, the optical axis perpendicular to it passes through the zenith: let ZPH in fig. 1, plate VI., be the true meridian, and Zsm the vertical circle described by the optical axis or line of collimation; then Hm , which is the measure of the angle at Z , is the deviation of the transit from the meridian.

Let $s's''\sigma$ represent the circle described by a circumpolar star, which is seen through the transit telescope at σ , its inferior passage, and at s , its superior. Now, when the transit is not in the meridian, the time from σ to s cannot equal the time from s' through s' and s'' to σ : for, P being the pole, the former time is proportional to the angle $\sigma P s$, or,

$$180^\circ - \angle s P s' - \angle \sigma P s''.$$

the latter to

$$180^\circ + \angle s P s' + \angle \sigma P s''.$$

834. Hence, if the interval between the inferior and superior passage should be less than the interval between the superior and inferior, the plane in which the transit moves from the zenith to the north of the horizon (P being the north pole) is to the eastward of the true meridian.

835. But in order to estimate the quantity of deviation from the observed difference of intervals between the passages, we must compute the angles $s P s'$ or $s P Z$, and $\sigma P H$.—now

$$\sin. s P Z = \sin. s Z P \times \frac{\sin. Z s}{\sin. P s'}$$

$$\sin. \sigma P H = \sin. \sigma P Z = \sin. s Z P + \frac{\sin. Z \sigma}{\sin. P \sigma}$$

$$\text{Let } \angle s Z P \text{ (measured by } Hm) = Z,$$

$$P s = P \sigma = \pi$$

the latitude of the place ($= HP) = L$. Then since Z , or the deviation from the meridian is, by the conditions, very small, we have, nearly

$$\sin. Z = Z.$$

$$\begin{aligned} Z s &= Z P - P s = 90^\circ - (L + \pi), \\ Z \sigma &= Z P + P s = 90^\circ - (L - \pi), \\ \text{consequently, } s P Z \text{ (which is, nearly, = its sine)} \\ &= Z. \cos. \frac{(L + \pi)}{\sin. \pi} = Z. (\cos. L \cos. \pi - \sin. L), \\ \text{and } \sigma P H &= Z. \frac{\cos. (L - \pi)}{\sin. \pi} - Z (\cos. L \cos. \pi + \sin. L). \end{aligned}$$

Hence, the time from σ to $s = 180^\circ - 2 Z \cos. L. \cot. \pi$,

and from s to $\sigma = 180^\circ + 2 Z \cos. L. \cot. \pi$;

let the former time = 12 h. — Δ ,

the latter = 12 h. + Δ ;

then, since 180° is the angular measure, or exponent of twelve hours of sidereal time,

$$12 \text{ h.} - \Delta = 12 \text{ h.} - 2 Z. \cos. L. \cot. \pi,$$

$$12 \text{ h.} + \Delta = 12 \text{ h.} + 2 Z. \cos. L. \cot. \pi,$$

$$\text{whence } Z = \frac{\Delta}{2 \cos. L. \cot. \pi}.$$

$$\text{or } = \frac{\Delta}{2} \text{ sec. } L \tan. \pi.$$

836. The plane in which the line of collimation moves is brought into the plane of the meridian by means of a screw; and supposing the adjustment nearly effected, it may be completed in the following manner: Let the time of the transit of an equatorial star be noted on a particular day. Alter the inclination of the plane in which the line of collimation moves, by turning the screws once round, and observe the time of the star's next transit. If the difference between the sidereal times of transit be s seconds, then, s seconds of time corresponding to one revolution of the screw, it is easy to find the number of revolutions, or parts of a revolution, that will give the correction 2 , in the above equation; whence the adjustment may be made to any degree of accuracy.

837. Computing from the above formulæ for Z , we shall find that, in the case of Polaris, a deviation of ten seconds in the position of the transit instrument will, in the latitude of London, produce a difference of about seven minutes in the times between the upper and lower transits of the star; and in the case of Capella, a difference of only about twenty-five seconds. Hence, cæteris paribus, the pole-star is better adapted than Capella, to adjust, by the preceding method, a transit telescope to the plane of the meridian. The slow motion of the pole-star, however, in some measure detracts from this superiority. In small instruments it is hid for some seconds behind the wire. Even in the splendid ten feet transit, at Greenwich, it may be considered as hid for about a second.

838. Still, however, on the whole, this star is the most convenient one that can be made use of. The following is the method of making this adjustment by means of the transits of the pole-star and of a star which passes near the zenith of the place of observation. In our latitudes, for instance, if the transit deviate only slightly from the plane of the meridian, Capella would pass the meridian very nearly at the time of its passing the vertical wire of the telescope. Assume it to pass exactly, and note the difference between the time shown by the clock and the star's known right ascension. Observe the time when the

pole-star is on the meridian, (which will differ more from the star's right ascension than the transit of Capella did from its right ascension), and compute, from the difference between its true right ascension and the observed time of its transit, the deviation of the instrument, and adjust it accordingly.

839. This operation will give a near approximation to the required position; and by a repetition or two of the process, the adjustment may be effected with great precision.

840. The line of collimation being now supposed, by means of the previous adjustments, to describe a great circle passing through the celestial pole and the zenith of the observer, the transit instrument is in a fit state to note the passages of stars across the meridian. A star passes the meridian when it coincides with the centre *a*, fig. 3. plate IX., of the cross-wires; but if *d e* were truly vertical, a star on any point of *d e* would be on the meridian; hence it is desirable to make *d e* vertical, since we might then observe the star's transit on any part of that line. This may be easily done thus: Direct the transit telescope to some well-defined distant object, so that it is bisected by some point of *d e*; move the telescope upwards and downwards on its horizontal axis, and observe whether the same object is bisected by every part of *d e*, or whether it runs along *d e*. If it does, the wire is vertical, or the middle wire is a meridional wire; if it does not, the wire must be adjusted till the object coincides with it in every part.

841. In large instruments these various adjustments are made with considerable trouble and difficulty; and in order to prevent a repetition of these troublesome verifications, when the instrument is once adjusted to the plane of the meridian, two marks are set up, one to the north and the other to the south, and their places determined by means of the meridional wire. They are first placed by means of the instrument, adjusted by the astronomical means above explained, and they are subsequently used to bring the instrument into the meridian, should it become deranged.

842. Besides the meridional wire, it is usual to place on each side of it, and at equal distances from it, parallel side wires, to check the middle wire and to supply its place, if from clouds or other accidents, an observation on it should not be obtained. The old transit, at Greenwich, had four side wires, or, in all, five wires. The present one has seven; though only five are in general used. In fig. 2, plate IX. five wires are represented, and numbered 1, 2, 3, 4, 5.

843. If the wires are equidistant, then the fifth part of the sum of the times at which a star is observed on the several wires, will be the time of its passing the meridian, and it ought, if the observation is well made, to agree with the time of passing the middle wire.

844. But the fact is, we are not able to note absolutely the times at the several wires; for probably no beat of the pendulum will happen exactly when the star is on the wire. The observer is obliged to estimate to the best of his judgment, the fraction of a second sum, the last

beat of the pendulum, when the star is on the wire. A tenth or two of a second may be put down too much at one wire, and too little at another; but the errors will probably in a great degree compensate each other, and the result will certainly be entitled to more confidence than a single observation at the middle wire.

845. It will soon be perceived by the observer, that stars near the equator, pass more speedily from wire to wire than stars near the pole. It is easy to prove that the time of a star's describing small spaces perpendicular to the meridian varies as the secant of its declination. For (fig. 1, plate IX.) let *P* represent the pole *P e*, *P f*, two quadrants; let *s t* represent the interval of the wires, which, by reason of its smallness is nearly coincident with *s r t*. Take $e q = s t$; then by the revolution of the earth or star apparently moves from *s* to *t* in the same time that another moves from *e* to *f*. But the time through *s t* (= the time

through *e f*) = time through $e q \times \frac{e f}{e q} =$ time

through $e q + \frac{e f}{s t} =$ time through $e q + \frac{\text{rad.}}{\cos. s e}$

= time through $e q + \frac{\text{sect. } s e}{\text{rad.}}$ Hence, if the

time through *e q*, that is the time of an equatorial star crossing the interval *e q*, be given, the time of crossing an equal interval, *s t*, varies as the secant of the star's declination.

846. There is, however, no star exactly in the equator; but the equatorial time of a star's running from wire to wire, may be readily obtained from the time which a star of known declination is observed to take. Let *t* be the observed time, and *d* the declination, then $t, \text{sect. } d =$ the equatorial time.

847. By the preceding methods, the upright wires of the telescope may be adjusted vertically, and the true intervals between the wires found in parts of sidereal time. To know whether the wires, which ought to be at right angles to the former, are truly horizontal, direct the telescope towards a star near the equator, and if the star entering at *h*, plate IX. fig. 2, in an inverting telescope, run along *h f*; then *h f* is horizontal.

848. This test of horizontality is strictly true only with respect to a star in the equator. If the star be out of the equator, it cannot be bisected during the whole of its passage from *h* to *f*; for the star then describes the arc of a small circle. In fig 1, plate IX. let *s m t* be an arc of a great circle; then a star describing *s m t* would seem to an eye situated in a plane passing through *s m t* and *s t*, to describe *s t*; but *s r t*, part of a small circle parallel to *e f*, is the star's apparent path, which coinciding at its extremities with the chord *s t* would appear, in the astronomical telescope, to describe a curve below the cross horizontal wire, the apparent curvature of the path increasing with the declination. There are, however, many stars near enough the equator to make this adjustment, without reference to the apparent curvature of their paths in the transit instrument, as they will differ from straight lines by a quantity too small to be estimated.

849. We have hitherto spoken only of the transits of stars, which are but as points without disks. The sun and the moon, however, have

disks, but no marked points for their centres; and the transit of a heavenly body means the transit of its centre. With respect to the sun, the time at which his first or preceding limb touches each wire is noted, and the time at which his following limb comes to the same wire is also noted, and the sum of the times of observation divided by the number of observations, gives the time at which his centre is on the meridian.

850. It is seldom, however, that the transit of both limbs of the moon can be observed; but the mean of the times at which her enlightened limb is in contact with the several vertical wires, is the time at which that limb is on the meridian; and adding to this, or subtracting from it, the time that the moon takes to move over a space equal to her own semidiameter, according as the east or west, the following or preceding limb is observed, we obtain the time at which her centre is on the meridian.

We have judged it right to devote so much space to the description of the circle and transit instruments, as in the present state of as-

tronomical science, they, with the astronomical clock, are the capital instruments of our observatory.

851. 10. The Equatorial or Portable Observatory; an instrument designed to answer a number of useful purposes in practical astronomy, independent of any particular observatory, may be made use of in any steady place, and performs most of the useful operations in the science. The principal parts of this instrument, plate XIII. fig. 3, are, 1. The azimuth or horizontal circle A, which represents the horizon of the place, and moves on a long axis B, called the vertical axis. 2. The equatorial or hour circle C, representing the equator, placed at right angles to the polar axis D, or the axis of the earth upon which it moves. 3. The semicircle of declination E, on which the telescope is placed, and moving on the axis of declination, or the axis of motion of the line of collimation.

852. These circles are measured and divided as in the following table:

Measures of the several circles, and divisions of them.	Radius. In dec.	Limb divided to	Nonius of 30 given seconds.	Divided on limb into parts of inc.	Divided by Nonius into parts of inc.
Azimuth or horizontal circle.	5 1	15'	30"	45th	1350th
Equatorial or hour circle.	5 1	{ 15' 1' in time.	{ 30' 2" }	45th	1350th
Vertical semicircle for declination or latitude.	5 5	15'	30"	42nd	1260th

853. 4. The telescope in this equatorial may be brought parallel to the polar axis, as in the figure, so as to point to the pole star in any part of its diurnal revolution: and thus it has been observed near noon, when the sun has shone very bright. 5. The apparatus for correcting the error in altitude occasioned by refraction, which is applied to the eye-end of the telescope, and consists of a slide G, moving in a groove or dovetail, and carrying the several eye-tubes of the telescope, on which slide there is an index corresponding to five small divisions engraved on the dovetail; a very small circle, called the refraction circle, H, moveable by a finger screw at the extremity of the eye end of the telescope; which circle is divided into half minutes, one entire revolution of it being equal to 3' 18", and by its motion raises the centre of the cross hairs on a circle of altitude; and a quadrant, I, of 1½ inch radius, with divisions on each side, one expressing the degree of altitude of the object viewed, and the other expressing the minutes and seconds of error occasioned by refraction corresponding to that degree of altitude. To this quadrant is joined a small round level, K, which is adjusted partly by the pinion that turns the whole of this apparatus, and partly by the index of the quadrant; for which purpose the refraction circle is set to the same minute, &c. which the index points to, on the limb of the quadrant; and if the minute, &c. given by the quadrant exceed the 3' 18", contained in one entire revolution of the refraction circle, this must be set to the excess above one or more of its en-

tire revolutions; then the centre of the cross hairs will appear to be raised on a circle of altitude to the additional height which the error of refraction will occasion at that altitude.

854. To adjust this instrument make the line of collimation to describe a portion of an hour-circle in the heavens; in order to which, the azimuth circle must be truly level, the line of collimation, or some corresponding line represented by the small brass rod, M, parallel to it, must be perpendicular to the axis of its own proper motion; and this last axis must be perpendicular to the polar axis; on the brass rod M, there is occasionally placed a hanging level, N, the use of which will appear in the following adjustments.

855. The azimuth circle may be made level, by turning the instrument till one of the levels is parallel to an imaginary line joining two of the feet screws; then adjust the level with these two feet screws; turn the circle half round, i. e. 180°; and, if the bubble be not then right, correct half the error by the screw belonging to the level, and the other half error by the two feet screws; repeat this till the bubble comes right; then turn the circle 90° from the two former positions, and set the bubble right, if it be wrong, by the foot screw at the end of the level; when this is done, adjust the other level by its own screw, and the azimuth circle will be truly level. The hanging level must then be fixed to the brass rod by two hooks of equal length, and made truly parallel to it: for this purpose make the polar axis perpendicular or nearly perpendicular to the ho-

hizon; then adjust the level by the pinion of the declination semicircle; reverse the level and, if it be wrong, correct half the error by a small steel screw that lies under one end of the level, and the other half error by the pinion of the declination semicircle; repeat this till the bubble be right in both positions.

856. To make the brass rod on which the level is suspended at right angles to the axis of motion of the telescope or line of collimation, make the polar axis horizontal, or nearly so: set the declination semicircle at 0° , turn the hour circle till the bubble comes right; then turn the declination circle to 90° ; adjust the bubble by raising or depressing the polar axis; first by hand till it be nearly right; afterwards tighten, with an ivory key, the socket which runs on an arch with the polar axis; and then apply the same ivory key to the adjusting screw at the end of the said arch, till the bubble comes quite right; then turn the declination circle to the opposite 90° ; if the level be not then right, correct half the error, by the aforesaid adjusting screw at the end of the arch, and the other half error by the two screws which raise or depress the end of the brass rod. The polar axis remaining nearly horizontal as before, and the declination semicircle at 0° , adjust the bubble by the hour circle; then turn the declination semicircle to 90° , and adjust the bubble by raising or depressing the polar axis; then turn the hour circle twelve hours; and if the bubble be wrong, correct half the error by the polar axis, and the other half error by the two pair of capstan screws at the feet of the two supporters on one side of the axis of motion of the telescope; and thus this axis will be at right angles to the polar axis.

857. The next adjustment is to make the centre of cross hairs remain on the same object, while the eye-tube is turned quite round by the pinion of the refraction apparatus. For this adjustment, set the index on the slide to the first division on the dovetail; and set the division marked $18''$ on the refraction circle to its index; then look through the telescope, and with the pinion turn the eye-tube quite round; and if the centre of the hairs does not remain on the same spot during that revolution, it must be corrected by the four small screws, two and two at a time, which will be found upon unscrewing the nearest end of the eye-tube that contains the first eyeglass; repeat this correction till the centre of the hairs remains on the spot looked at, during an entire revolution.

858. To make the line of collimation parallel to the brass rod on which the level hangs, set the polar axis horizontal, and the declination circle to 90° ; adjust the level by the polar axis; look through the telescope on some distant horizontal object, covered by the centre of the cross hairs; then invert the telescope, which is done by turning the hour circle half round, and, if the centre of the cross hairs does not cover the same object as before, correct half the error by the uppermost and lowermost of the four small screws at the eye-end of the large tube of the telescope. This correction will give a second object, now covered by the centre of the hairs, which must be adopted instead of the first object: then invert the teles-

cope as before; and if the second object be not covered by the centre of the hairs, correct half the error by the same two screws which were used before. This correction will give a third object, now covered by the centre of the hairs, which must be adopted instead of the second object; repeat this operation till no error remains; then set the hour circle exactly to 12 hours (the declination circle remaining at 90° as before); and, if the centre of the cross hairs does not cover the last object fixed on, set it to that object by the two remaining small screws at the end of the large tube, and then the line of collimation will be parallel to the brass rod.

859. For rectifying the nonius of the declination and equatorial circles, lower the telescope as many degrees, minutes, and seconds, below 0° , or \bar{A} , on the declination semicircle as are equal to the complement of the latitude; then elevate the polar axis till the bubble be horizontal, and thus the equatorial circle will be elevated to the co-latitude of the place; set this circle to 6 hours; adjust the level by the pinion of the declination circle; then turn the equatorial circle exactly 12 hours from the last position; and if the level be not right, correct one half of the error by the equatorial circle, and the other half by the declination circle; then turn the equatorial circle back again exactly 12 hours from the last position; and if the level be still wrong, repeat the correction as before till it be right, when turned to either position; that being done, set the nonius of the equatorial circle exactly to 6 hours, and the nonius of the declination circle exactly to 0° . The uses of this equatorial are:

860. 1. To find the meridian by one observation only: for this purpose, elevate the equatorial circle to the co-latitude of the place, and set the declination semicircle to the sun's declination for the day and hour required; then move the azimuth and hour circles both at the same time, either in the same or contrary direction, till the centre of the cross hairs in the telescope exactly covers the centre of the sun. When that is done, the index of the hour circle will give the apparent or solar time at the instant of observation; and thus the time is gained, though the sun be at a distance from the meridian. Then turn the hour circle till the index points precisely at 12 o'clock, and lower the telescope to the horizon, in order to observe some point there in the centre of the glass, and that point is the meridian mark found by one observation only; the best time for this operation is three hours before or three hours after twelve at noon.

861. 2. To point the telescope on a star, though not on the meridian, in full day light. Having elevated the equatorial circle to the co-latitude of the place, and set the declination semicircle to the star's declination, move the index of the hour circle till it point to the precise time at which the star is then distant from the meridian, found in tables of the right ascension of the stars, and the star will then appear in the glass. Besides these uses, peculiar to this instrument, it is also applicable to all the purposes to which the principal astronomical instruments, viz. a transit, a quadrant, and an equal altitude instrument, are applied.

862. This instrument, however, like all instruments that profess to do much, does nothing so well as instruments whose objects are more limited. The splendid equatorial of sir Geo. Shuckburgh, now at the royal observatory at Greenwich, is seldom used, except to observe comets when they cannot be seen at the time of their transit. And even for that purpose it is now likely to be superseded, by an equatorial lately put up in the north-west turret of the observatory, by Mr. Dollond. The polar axis of this equatorial is fixed in the direction of the earth's axis, and carries round with it a vernier which points out right ascensions, on an equatorial circle, fixed at its lower extremity; and a circle at right angles to the equatorial is attached to the axis, which shows at once the distances of objects to which its telescope is pointed.

863. We shall conclude the subject of astronomy with the following catalogue of sixty of the principal fixed stars, recently published by astronomer royal, who remarks upon it that 'The catalogue will require a small correction, common to every star, both in right ascension, and north polar distance. The correction in R. A.

will be subtractive, and may amount to nearly one-tenth of a second in time. The correction in N P D will, I imagine, be likewise subtractive, and will not exceed a quarter of a second.

'It is divided into four classes, according to the supposed degree of accuracy of each. The stars of the first class are those that have been determined both by direct vision, and reflection. The second class consists chiefly of those too near the zenith to be observed by reflection. The third class is not quite so exact as the second, and the fourth still less exact than the third. The errors of the first and second classes, I should think, can rarely exceed a quarter of a second: in the third class the error may probably amount to double that quantity; and the fourth class cannot be relied on but to the nearest second. Regulus ought, from the number of observations, to be in the first class; but, from some accidental discordances, I have reserved it for future examination. The errors are quite independent of the common error above-mentioned, the exact amount of which will be the future subject of investigation.'

864. *Catalogue of the Right Ascensions and North Polar Distance of Sixty Stars, for the beginning of 1823, by J. POND, Esq. Astronomer Royal.*

I N D E X.

- ABERRATION of light, discovered by Bradley, 56. 61. 373. Cause of, investigations respecting, formulæ and tables for computing, 374—386.
- ADAM supposed to have been acquainted with astronomy, 3.
- ALMAGEST, compiled by Ptolemy, 31. Commented on by Purbach, 38. and completed by Muller, 39.
- ALPHONSINE tables composed, 37. and corrected, 38.
- ALTITUDE of the sun observed by Pytheas, 27.
- AMAZON river, five high, and four low tides in, at once, 480.
- AMERICANS acquainted with astronomy, 17.
- ANNUAL motion of the earth illustrated, 410—413.
- ANOMALY, mean and true, 602. Eccentric, 604. To find true on terms of mean, 604—609.
- ANTARCTIC circles defined, 418.
- ANTEDILUVIANS acquainted with astronomy, 3—5.
- ANTICIPATION of the equinoxes, 429—431.
- APHELION or APSIDE of the planets, 601. Method of finding place and motion of, 610. 617. 647. Table of places of, 235.
- APOGEE, motion of the sun's, computed by Albatagnus, 33. Defined, 353. 360.
- ARABIANS cultivated astronomy, 32, 33.
- ARACTA, tables formed for the meridian of, 33.
- ARCTIC circle defined, 416.
- ARCTURUS, half a degree more southerly than observed by the ancients, 208.
- ARMILLARY sphere erected at Alexandria, 28.
- ASCENDING node of planets, table of places of, 234. Defined, 335. 673.
- ASPECTS of the planets, 340.
- ASTRONOMICAL instruments described, 776—862. Quadrants, 780—789. Mural circle, 790—811. Equatorial sector, 812—815. Transit Instrument, 816—850. Equatorial, 851—861. Machinery for illustration, 762—775.
- ASTRONOMICAL Society of London, 74. 180.
- ASTRONOMY, etymology of, definition of, sublimity and usefulness, 2. Antiquity of, 3—19. History of, 3—76. Various systems of, 210. 218. True system of, 219. 235.
- ATHENIANS erect a statue to Berosus the astronomer, 27.
- ATLANTIC Ocean, tides on the, less than on the Pacific, 479.
- ATMOSPHERE, lunar, 170. Supposed to have tides, 483. Light refracted by it, 501—511.
- ATMOSPHERES, Venus and Mars have, 112, 113. Doubtful whether Mercury has one, 111.
- ATKINSON on refraction, 510, 511.
- ATTRACTION of the great mountains affects the plumb line, 60. Dr. Herschel's ideas of the effects of attraction of the heavenly bodies, 194. 200. Its power supposed to be balanced by projectile forces, 207. Effects of attraction on the motions of the planets, 254. 327.
- ATTRACTIVE force, law of, between different planets, 202—314.

- AXIS** of the earth described, 369. 420.
- AZIMUTH** circle, utility of the, 788. Method of adjusting, 855.
- BALTIC** sea has no sensible tides, 482.
- BEARDED** comet explained, 145.
- BELTS.** See **JUPITER**.
- BENARES**, a celebrated observatory at, 13.
- BLACK** sea has no sensible tides, 482.
- BODIES** of the sun and planets described, 303—307.
- BODE**, remarkable analogy among the distances of the planets noticed by, 141.
- BRINKLEY**, 503. 588.
- BULL'S** eye, more southerly than the ancients placed it, 208.
- CALIPPIC** period corrected by Hipparchus, 30.
- CAMBRIDGE** observatory, 75.
- CARTESIAN** system, 218.
- CASPIAN** sea has no sensible tides, 482.
- CELESTIAL** bodies, appearances of the, as seen by the naked eye, 77—97. Or seen through telescopes, 98—149.
- CENTRAL** forces, 236—247. Application of to the planetary theory, 248—253. Obeyed by comets, 258.
- CERES**, 69. 114
- CHALDEA**, a country proper for astronomical observation, 18.
- CHALDEANS**, early astronomers, 12. 18. 19.
- CHINESE**, said to have been taught astronomy by Noah, 7. Their superstition, 756.
- CHRONOLOGY**, eclipses useful in, 757.
- CIRCLES**, described by the planets, 328—336.
- CLAIRAUT** computed the orbit of a comet, 178, 179.
- COLD**, cause of in winter, 423—425.
- COMETS**, written on by Muller, 39. Observed by Werner, 41. And Hevelius, 44. Paths of, discovered by Kepler, 48. Places of observed, and elements computed by Bradley, 61. Number and appearances to the eye, 87. Apparent magnitude, 88. Appearances through telescopes, 142—146. Of their tails, 144—146. Fancies respecting, 172. Perihelion distances, 175. Conjectures respecting tails, 176. Methods of determining the orbits of, 294—302. Resistance of aether inferred from the motion of Guka's, 180.
- COMMUTATION**, angle of, 624.
- CONJUNCTION** of Jupiter and Saturn observed by Tycho Brahe, 47.
- CONJUNCTIONS** of planets, 340, 341.
- CONSTELLATIONS**, number of the Chinese, 7. How marked, 8. When first used by the Greeks, 22, 23. Names of the ancient, 595. And of the modern, 596, 597. Number of stars in each, 595—597.
- COPERNICAN** SYSTEM published, 42. Improved, 43. Account of, 219—235. Much opposed at first, 220. Confirmed by Newton, 221.
- CORPUSCLE**, attraction of a line on, 313. Of a plane on, 314. Of a sphere on, 315.
- CRABBIT**, Mr. sees the first transit of Venus ever observed, 51. 583.
- CRYSTALLINE** heavens, an erroneous notion in the Ptolemaic system, 213.
- CURTATE** distance, 625.
- DARKNESS**, extraordinary, supposed to be caused by comets, 761.
- DECLINATION**, sun's, table of, 550. Principal fixed stars, 363.
- DELUGE**, supposed to have been caused by a comet, 177.
- DENSITY** of the whole matter on the earth, 67. Proportional of the sun and planets, 235. 320—327.
- DESCENDING** node, defined, 673.
- DIAMETER** of the sun and planets, 234.
- DICHOTOMY** of the moon, used by Aristarchus to determine the sun's distance, 28.
- DIRECT** motion of a planet defined, 357.
- DIURNAL** rotations of the sun and planets, 234. Of the earth illustrated, 410—413.
- DISTURBING** effects of planets on each other, more easily computed from their smallness with respect to the sun, 266.
- DOUBLE** stars, some, revolve round each other, 186. Herschel and South on motions of, 71.
- DRUIDS** early astronomers, 27.
- EARTH**, figure of the, dispute concerning, 60. Mean density of matter in it, 67. The motion of maintained by Pythagoras and Nicetas, 219. Its revolution, diurnal motion, proportional density, &c. 233. 235. 327. Distance from the sun, 366. Diameter and motion, *ib.* Form, 366—368. Angle of its axis, 369. Its motion round the sun proved, 370—386. Objection, 387. Revolves on its axis, 383—409. Its motions illustrated, 411—431. Appears as a moon to the Lunarians, and the largest body in the universe, 435. Irregularity of the form of its orbit, 276.
- ECCENTRICITIES** of the planets, 233. Method of finding, 648.
- ECCENTRICS**, a term used in the Ptolemaic system, 214.
- ECLIPSES**, the theory of, known to the Chinese, 9. Accounts of, collected by Hipparchus, 50. Preliminary observations respecting, 666—678. Rules and examples for calculating, 679—745. For a general solar eclipse, 746—753. Eclipses of Jupiter's satellites, 25—760. Cometary eclipses, 761. Causes of explained, 772.
- ECLIPTIC**, obliquity of the, in Ptolemy's time, 28. Fixed by Albatagnius, 33. Observed by Arzachel, 34. Corrected by Werner, 41. Derivation of the name, 330. To find the obliquity of, 331. 333. 563, 564. Periodical variation in obliquity, 393. Comprehended in the zodiac, 593.
- EGYPT**, a country adapted to astronomical observations, 18.
- ELLIPTICAL** orbits of the planets discovered by Kepler, 48. Of Saturn's satellites, 136. Of comets, very eccentric, 225.
- ELONGATION**, greatest of inferior planets, 235. Defined, 362—629.
- EPHEMERIDES**, made by Purbach, 38.
- EPICYCLE**, a term in the Ptolemaic system, 214.
- EQUATION** of centre, 607, 608.
- EQUATION** of time, table of, 543. Auxiliary table for reducing to subsequent year, 544.
- EQUATORIAL** described, 851—862.
- EQUINOCTIAL**, obliquity of the, 420. Cause of the seasons, 420.
- EQUINOCTIAL** point, method of finding the, 565.
- EQUINOXES**, precession of the, 33—41.
- EVENING** star, 83.
- FACULE** of the sun explained, 103.
- FALLING** bodies, velocity of, 273, 274.
- FIELDS** of stars defined, 188.
- FIXED** stars, table of proper motions of, 209. Catalogue of principal, 864.
- FO-HE**, emperor of China, taught the Chinese astronomy, 7.
- FORCES**, central, 236. 242. 247.
- GALAXY.** See **MILKY WAY**.
- GEOCENTRIC** latitude defined, 334.
- GEOCENTRIC** motion explained, 342, 343. 351.
- GEOCENTRIC** observations, method of reducing to heliocentric, 618, 625.

GEORGIAN planet, Georgium Sidus, Uranus, or Herschel, discovered by Herschel, 139. Apparent magnitude, *ib.* Diameter, *ib.* Periodic revolution, *ib.* Has six satellites, *ib.* Remarkable peculiarity in the position of their orbits, *ib.* Theoretical deduction of La Place respecting, *ib.* Periods and elongations of satellites, 140.

GNOMON, the use of a, known to the Chinese, 9. Used by Pytheas, 27. One erected at Bologna, 58.

GRAVITATION defined, 260. Its effects on the planets, 261—269. 307. And satellites, 270—277. On the moon in particular, 275—285. Illustrated, 286—292. Is diffused through the substance of the celestial bodies, 303—318.

GREEKS, probable origin of their astronomy, 22—25. Vitruvius's account of it, 27.

HALLEY, Dr. examines Hevelius's instruments, and makes observations along with him, 53. Makes a catalogue of the fixed stars; discovers the acceleration of the moon; points out the method of finding the distance of the sun from the transit of Venus, 59.

HARDING, discovered Juno, 69.

HARVEST moon, rises sooner than any other, 486. Reasons of this, 487—492. Goes through a course of more and less beneficial states, 493.

HEAT, formula for determining time of day when greatest, 426.

HEAVENS, general appearance of the, 80. Divisions of the stary, 589—597.

HELIOCENTRIC circle defined and described, 328—330.

HELIOCENTRIC latitude defined, 334.

HERSCHEL, Dr. improves reflecting telescopes, 57. Constructs very powerful ones, and discovers a new planet, with satellites, 68. His observations on Venus, 112. And on Mars, 113. Sees a satellite and its shadow both on the disk of Jupiter, 125. Discovers the double ring of Saturn, 131—133. A sixth and seventh satellite, 134. And vast numbers of nebulæ, 146. Observes eruptions of the lunar volcanoes, 167. Forms a new theory of the universe, 187. His theory of the heavens, 195—203. Proposes a method of determining the parallax of the fixed stars, 586.

HERSCHEL, Jun. on double stars, 71.

HERSCHEL, the new planet, so named by foreign astronomers, 68. See **GEORGIUM SIDUS**.

HIGH water, to find the time of, 484, 485.

HORIZONTAL parallax defined, 566. How to find it, 567.

HORIZONTAL sun and moon, apparent magnitude of the, 494. Accounted for by Alhazen, 495. Descartes and Wallis, 496, 497. Dr. Desaguliers, 498. And Dr. Smith, 499. Probable cause of, 500.

HUENNA, Tycho Brahe builds an observatory on, 47.

INCLINATIONS of the planetary orbits to the ecliptic, 234.

INDIANS early astronomers, 13.

INFERIOR planets defined, 227—335.

INSTRUMENTS, astronomical, described, 776—862.

JONES, constructed Greenwich mural circle, 790.

ITALY, great astronomers in, 63.

JULIAN year, excess of the, above the solar, 430.

JUNO, 116.

JUPITER, phenomena of, eclipses of, satellites of, 25. Conjunction of, with Saturn observed, 47. Occultation of, by the moon, 53. Eclipses of, by his satellites, observed by Cassini, 54. Theory of his satellites still imperfect, 62. His appearance to the eye, 85. And through a telescope, 118. A

satellite and its shadow seen on the planet at the same time, 125. Revolution of satellites on their axes, 126. Remarkable connexion among their periodic times, 127. Spots observed on him, 116. His figure and rotation, 119. His four satellites, 120. Account of these phenomena, 127. Other phenomena, 231. 233, 234, 235. Attractive power of Jupiter, 271, 272. Motion of light, from Jupiter to the earth, 374. Eclipses of his satellites very frequent, useful in finding the longitude, 760.

KATER observed a volcanic appearance in the moon, 167.

KEPLER and Newton's discoveries, distinctive nature of, 254.

KEPLER'S laws, 255—257.—Illustrated, 259, 260.

LATITUDE of a planet defined, 334. Methods of computing, 620. Terrestrial, methods of finding, 561, 562.

LIBRATION, 109, 447.

LIGHT, progressive motion of, discovered, 58. 373. Proportion of, in the planets, 235. Velocity and alienation of, 376—387. Affords evidence of the motion of the earth, 395. 408—411. Illustrated, 411—413. Quantity of, afforded by the earth to the moon, 435. Refraction of by the atmosphere, 500—516.

LOCAL zodiac described, 336.

LONDON bridge, time of tides arriving at, 480.

LONGITUDE, method of finding the, proposed by Werner, 41. By Dr. Halley, 59. Has since been carried into execution, *ib.* Longitude of a celestial phenomenon defined, 338. Method of computing, 620. Of places easily found in the moon, 438. Eclipses useful in determining it, 661, 664.

LUNAR eclipses, two, at least, happen annually, 698. One visible, the other not, 699. Rules for calculating, 706—724. Exemplified, 772.

LUNAR tables computed, 62. When the moon's place is most correctly in the syzygies, 723, 724.

LUNARIANS, appearance of the earth to the, 435, 436. 442. Have always equal day and night, 437—439.

LUNATIONS, no complete number of, finished without a fraction, 676. See **MOON**.

MACHINERY, astronomical, described, 762—775.

MACULE of the sun defined, 103.

MAGNITUDES of the celestial bodies, 561—588. Of the stars distinguished, 589.

MARS, his appearance to the eye, color, and other phenomena, 84. Appearance through a telescope, 113. Rules for deducing his distance, 575, 576. Obliquity of axis of rotation, appearance of snow about poles of, 113.

MARSEILLES, the gnomon early used at, 27.

MATTER, universal attraction of, proved, 67. 262. 303. 318. Diversity of, in the earth, 67. 262. And planets, 320—327.

MEAN distances of the planets, 233.

MEDITERRANEAN sea has no tides, 482.

MERCURY, appearance of, to the eye, 82. Through a telescope, 110. Mountains in, 111. Has phases similar to those of the moon, 231. Seen in conjunction with the sun, 345. And passing over his disk, 346. Table of occultations of, 665.

MERIDIAN, rules for finding the, 517—522. To place a transit instrument in, 831—839.

MICROMETER improved, 57. Necessary for measuring small angular distances, 779.

MILKY way, appearance of the, 96. Dr. Herschel discovers innumerable multitudes of stars in it; he views it by fields, 188. And supposes the sun to be set, 192. Gauges it, 194.

- MOON**, acceleration of the, determined by Ebn. Yonnis's observations, 34. Discovered by Halley, 59. Her appearance to the eye, 78. And through a telescope, 109. Great inequalities on her surface, 165. Supposed to be mountainous; attempts made to measure their height, 166. Volcano observed in her by Kater, 167. Also by others, *ib.* Dr. Herschel's estimate of the height of the lunar mountains, 166. Conjectures respecting the moon's substance, 168. And her spots, 169. Atmosphere of, discovered by Ramage, Ross, and Comfield, 170. Enquiry whether the moon is inhabited, 171. Her orbit and motion, 271, 272. Illustrated, 273—292. Her conjunction, 340, 341. And peculiar phenomena, 432—449. She influences the tides, 450—482. Proportion of her power to that of the sun in moving the sea, 459. Her appearance at the full in harvest, 486. Causes of it, 487—493. Appearance near the horizon, 494. Various reasons assigned for it, 490—500. Causes of her eclipses, 666—678. Rules for computing them, 680—724. To find her way from the sun, 725—730. Her color, &c. during an eclipse, 754, 755. Her distance from the earth less than formerly, 758. Her various phases exemplified, 768, 770, 772. Method of delineating her visible disk, 447. Parallax indicates the shape of the earth, 578.
- MORNING** star, 83.
- MOTION**, planetary, laws of, 255—259. 344. 364. Of light, 373—386.
- MOTIONS** of comets, 293—302. Of planets, in antecedence and consequence, defined, 336. Direct, 344, 357. And retrograde, 344—358. Progressive of light, 408, 409. Annual and diurnal, of the earth, 410—413. 531.
- MURAL** quadrant described, 781—787.
- MURAL** circle, and its uses, described, 790—811.
- NAUTICAL** almanack, or Nautical Ephemeris, annually published, 62—66.
- NEAP** tides, cause of the, 455. 472. 476.
- NEBULE** explained, vast numbers of, discovered by Herschel, 149. His account of them, 188—205.
- NEW** stars, accounts of several, 90—95.
- NEWTON**, Sir Isaac, constructs reflectors with spherical speculums, 55. Brings theoretical astronomy to perfection, 56. Determines the figure of the earth, 60. Confirms the Copernican system, and lays down the fundamental laws of motion and gravity, 221.
- NODES** defined, 621. Method of finding when a planet is in, *ib.* To find the motion of the moon's, 290, 290. Line of the nodes defined, 335.
- NONAGESIMAL** degree defined, 443.
- NORTH** Pole star, appearance of the, 79, 80.
- NUTATION**, natural, and cause of, 401. Formulae and tables for computing, 402—407.
- OBLIQUITY** of ecliptic, periodical variation in, 393. Method of finding, 563, 564.
- OBSERVATORIES**, the towers of Babel and Belus supposed to have been, and the pyramids of Egypt, probably used as such, 18.
- OBSERVATORY**, principal instruments in, described, 776—862.
- OBSERVATORY**, portable or equatorial, described, 851—862.
- OCCULTATION** of Jupiter by the Moon, observed, 53. 170. And of Saturn, *ib.*
- OCCULTANTS** of the moon described, 440.
- OTHERS** discovered Pallas and Vesta, 69.
- OPPOSITION** defined, 340. Mark of, 341.
- ORBITS** of the planets, inclination of the, to the ecliptic, 234. Of the moon, 286—291. Method of finding the form of, 644. Inclination of, 643. Eccentricity, 648. Place of a planet in an elliptical orbit, 598—609.
- ORION**, number of stars in, 148.
- ORRERY**, erected by Archimedes, 30. Description of the grand, made for King George I., 762—764. Of Mr. Ferguson's, 765—772.
- OSYMANDIUS**, an astronomical circle on the monument of, 18.
- PALLAS**, 69. 115.
- PARALLAX** of planets, methods of determining, 577. Of fixed stars, no sensible quantity, 588.
- PARABOLA** of a comet, method of finding the, 297—302.
- PENDULUM**, a test of velocity, 274. Cause of its vibration, 304. Vibrates most quickly near the poles, 397.
- PENDULUM** clock, 777.
- PENUMBRA**, method of finding the place first or last touched by, 752.
- PERIGEE** defined, 353—360.
- PERIOD** of eclipses, 676. See **ECLIPSES**.
- PERIODICAL** revolutions, 233. 630.
- PISCES** and Aries, appearance of the moon in, 487, 492.
- PIAZZI** discovered Ceres, 69.
- PLANETARIUM** erected by Archimedes, 29. Mr. Jones's described, 771.
- PLANETS**, a theory of the, written by Muller, 39. Their appearance to the eye, 81—86. Number, 81. Apparent magnitudes and motions, 86. Their names and order, 222—227. Are all opaque bodies, 230. Their periods, distances, and eccentricities, 233. Secondary planets, 270—292. Their circles defined and described, 328—333. 336. Their latitude, 334—337. Method of computing latitude of, 620. Longitude, 357. Method of computing, 620. Conjunctions, oppositions, and aspects, 340—349. Stationary appearances, 350. 354. Motions, 355, 356. Direct, 357. Retrograde, 358. In apogee and perigee, 353. 360. Periods of return, 361—364. Methods of finding the parallax of the planets, 566—579. Their distances, 580—582. 609. 630—649. Periodic times, 630. Method of computing densities, 320—326. Comparative view of densities, 327.
- PLEIADES**, number of stars in, 148.
- POLE**, to find the place of, in projecting a solar eclipse, 750.
- POLES** of the earth, bodies heaviest when near, 397.
- POND**, astronomer royal, 71, 588.
- PRECSSION** of the equinoxes, 390—392. Table and formulae for computing effect of, 394—396.
- PROGRESSIVE** motion of light proves the motion of the earth, 373—386.
- PROJECTILE** forces, supposed by Dr. Herschel to counteract the power of attraction, 207. Rendered probable by changes in the positions of stars, 208.
- PROPORTIONAL** distances of the planets from the sun, 233.
- PROPORTIONS** of light, heat, bulk, and density of the planets, 235.
- PYTHAGOREAN** system of astronomy, taught by Philolaus, 25. And by Aristarchus, 28. Carried into Italy, Gaul, and Egypt, 26, 27. Restored by Copernicus, 42. 218.
- PYTHAGORAS** held comets to be of the nature of planets, 172.
- QUADRANT**, mural, described, 781—787.
- QUADRANT**, portable, described, 788, 789.
- QUADRANT**, reflecting, invented, 56.

QUADRATURE defined, 340, 341.

RADIUS, vector, 601. Method of finding length of, 609. 649.

REFRACTION of light by the atmosphere, 501. Illustrated, 502. Method of computing by Brinkley, 504—509. Table of mean refractions, by Mr. Henry Atkinson, 511.

REFRACTIONS, the use of, in astronomy, shown by Alhazeni, 34. And Vitello, 37.

RETROGRADE motion of a planet defined, 344.

REVOLUTION of the heavens, only an apparent motion, 409.

REVOLUTION, synodical, method of determining, 650—656.

RIGHT Ascension, method of computing, of the stars, 620. Table of principal, 865. Of the sun, 558. 560.

RING. See SATURN. To find the form of, 137.

SAMARCAND, the latitude of, determined by Ulug Beg, 35.

SATELLITES, four revolve round Jupiter, 120. Seven round Saturn, 134. And six round Herschel, 139.

SATURN, his ring discovered, 50. 128. And five of his satellites, 54. His appearance to the naked eye, 85. And through a telescope, 128. His ring described, 129, 130. Found by Dr. Herschel to be double, 131. Not changeable, 132. Period of his revolution, 133. Seven satellites, 134. Their periodical revolutions and distances from Saturn, and greatest angular distance as seen from the earth, 135. Table to determine the apparent form of the ring, and of the orbits of satellites, 137, 138. Mutual attraction between Jupiter and Saturn, 267, 268. Their power, 272.

SCHROETER, 111. 113.

SEA, the ebbing and flowing of, the causes of, 450. 483.

SEASONS, causes of, the, 414. 423. Had fallen back from the error of the Gregorian calendar, 430. Rectified by the new style, *ib.* 431.

SECTOR, equatorial, described, 812. 815.

SEMITA LUMINOSA, or zodiacal light, 150—152.

SEMI Tychonic system, 217.

SEXTILE, definition and marks of, 341.

SHADOW of the earth always round, 367.

SIDERAL days defined, 525.

SIGNS, Chinese names of, the, 7. Defined, 336.

SOLAR days defined, 525.

SOLAR eclipses, of the shadow of the penumbra in, 687—693. When they can happen, 695. Number that may happen in a year, 698. Rules for computing, 731—753.

SOLAR noon, deviation of, from the clock, 541

SOLAR systems, ours, in motion, 208. Synoptic view of 222—227.

SOLAR systems, space universally filled with, 183.

SOUTHERN constellations, 596.

STARS, fixed, catalogues of, the, made by Hipparchus, 30. Ulug Beg, 35. William IV. of Hesse, 46. Tycho Brahe, 47. Flamsteed, 58. Halley, 59. Herschel, 68. Their aberration discovered, 56. Appearances to the eye, 79—81. Most numerous in the northern part of the heavens, 79—81. Liable to changes, 89. Their appearance through telescopes, 147, 148. Supposed to be suns, 181—186. Dr. Herschel's theory, 187. Observations of innumerable multitudes of stars, 188—205. His inferences, 205—208. Apparent changes of stars, *ib.* Are situated at an immense distance, shine by their own native light, 228. No method yet found to ascertain their distance, 584. Conjecture as to it, 585. Dr. Herschel's method, 586. Still insufficient, 587. Divisions of the stars, 589—597.

Number of, in different constellations, 595—597. Table of proper motion of, 209. Catalogue of principal, 865.

STYLE, reason for the change of, 430, 431.

SUN, spots on, the, discovered, 50. His parallax and distance computed, 64. His appearance to the eye, 77. And through a telescope, 98—108. His spots observed by Galileo, Scheiner, and Harriot, about the same time, 98, 99. Variety of dimensions, 100. Subject to increase and diminution, 101—103. Their velocity and uniform motion from east to west, 104. Other phenomena attending them 105—108. Dr. Long's account of them, 154. To find the time of their revolutions, 156, 157. Different opinions concerning them, 158. Dr. Wilson, 159—164. The sun supposed not to be in the centre of the universe, 192. Is at an immense distance, 229. Mutual gravitation between the sun and planets, 260—269. Action of the sun on the secondary planets, 270—292. Proportion of his action on both, 306—318. His conjunctions with the planets, 340—364. Is immensely larger than the earth, 370, 371. Proofs that the earth revolves round the sun, 371—413. And that the sun revolves on his axis, 388, 389. He is higher in summer than in winter, 421. And more distant, 423. Reasons for the greater heat in summer, 423—426. Periods of his completing a tropical revolution, 427. Appears to fall back with respect to the stars, 428. Reasons for the apparent increase of magnitude near the horizon, 494—500. The motion of the sun illustrated by supposing a fictitious sun moving in the equator, 533—541. The sun's parallax the most important problem in astronomy, 582. Table of the sun's declination for 174; with auxiliary table to find it for subsequent years, 550, 551. To find the moon's way from the sun in eclipses, 725—730. To calculate eclipses of the sun, 731—753.

SYNOPSIS of the sun and planets, 232—235.

SYSTEMS of astronomy, account of the most famous, 210—227. Of the Pythagorean, 212. Ptolemaic, 213, 214. Tychonic, 216. Semi Tychonic, 217. Cartesian, 218. And Copernican, 219—227.

TABLES, astronomical, published, 37. 48. 59. 62.

TELESCOPES, improvement of, 54—57. Various kinds of, used by astronomers, 778. 784. 816. To point the telescope of an equatorial to a star, 861.

TELESCOPIC stars defined, 589.

TIDES, theory of, 450—483. Causes of the spring and neap, 455. 472. 475, 476. Tides supposed in the atmosphere, 483.

TIME, methods of finding, 526—529. Equation of time, table of, 543, 544. Illustration of equation of time, 533—536. Explanation of, 537—541.

TIME keeper, recommended by Frisius to determine the longitude, 45.

TRAJECTORIUM Lunare, described, 773—775.

TRANSIT instrument, description and use of, 817—850.

TRANSITS of inferior planets over the sun; intervals at which they may happen, 657. 663. List of transits of Venus, 664. Of Mercury, 665.

TROPIC of Cancer described, 416. Of Capricorn, 418.

TROUGHTON, maker of one of the Greenwich mural circles, 71.

TWILIGHT, cause of, the, 512. Method of determining the time of shortest at any place, 513—515.

TYCHONIC system, account of, the, 216.

VELOCITY of the spots on the sun, 104. Of comets, greatest in their perihelion, 174. Of bodies, pheno-

mena of the, 237. 273. 274. Of the earth, 386. Of light, 396.

VENUS, the first transit of, ever observed, 51. The second and third observed at various places, inferences, 64. Her appearance to the eye, 83. And through a telescope; her phases and changes similar to those observed in the moon were first observed by Galileo; Dr. Herschel's observations and inferences; she has an atmosphere, and is probably a little larger than the earth, 112. Mountains in her, seen by Schroeter, 113. Periods of her transits, 346. 664. Her motions, 361, 362. Methods of deducing her parallax, 571, 572. 581, 582. Advantage of observing her transits, 582. Account of those that have been observed, 583.

VERNIER described, 785, 786.

VESTA, 69, 117.

VIBRATION of pendulums, cause of the, 304.

VISIBLE disk, moon's, method of delineating, 447.

VISIBLE eclipses, number of, in the year, 699.

UMBRE in the sun defined, 106, 107.

UNFORMED stars defined, 590.

URANIBURG, built by Tycho Brahe, 47.

URANOMETRIA, a work published by Bayer, 49.

URSA, major and minor, number of stars in, 595.

WHISTON, conjecture of, respecting comets, 177.

XIPHIAS, number of stars in the constellation, 596.

YEAR, the grand, Josephus's mention of, 4. Cassini's remark on, 5. The tropical and sidereal defined, 427. Civil and solar difference of, 429, 430. Rectified by the change of style, 430, 431.

ZENITH sector, invented by Graham, 56.

ZODIAC, Chinese divisions of the, 7. Etymology and definition of, 330. Division of, astral and local defined, 336. Extent of, 593.

ZODIACAL light, discovered by Cassini, 150. Described, 151—153. Reason for supposing that it is not connected with the solar atmosphere, 152.

ZONES, or belts round Jupiter, 54. 118.

ASTROPECTEN, in natural history, a species of star fish, composed of a central nucleus, furrowed like the shell of the common scallop, and parting into five principal rays, from each of which issue several transverse processes, covered with a hairy down.

ASTROPODIA, the star-stone. See ASTERIA.

ASTROSCOPE, an astronomical instrument, composed of two cones, on whose surface the constellations, with their stars, are delineated, by means whereof the stars may easily be known.

ASTROSCOPIA, the art of examining the stars by telescopes. Huygens improved this art considerably. See his *Astroscopia Compendiaria*.

ASTROTHEMATA, in astrology, the positions of the stars in a theme of the heavens.

ASTRUC (John), a celebrated French physician, was born in 1684, at the little town of Sauves in Languedoc. He studied at the university of Montpellier, and in 1717 was in great repute there as a teacher of medicine. His fame became so considerable that the king assigned him an annual salary, and appointed him to superintend the mineral waters in Languedoc. As Montpellier, however, did not afford sufficient scope for his genius, he removed to Paris, but soon after left it, having in 1729 accepted the office of first physician to the king of Poland. Upon the death of the celebrated Geoffroy, in 1731, he was appointed Regius Professor of medicine at Paris. Of his numerous writings the following are the principal: 1. *De Morbis Veneris*. 2. *Memoirs relative to the Natural History of Languedoc*. 3. *A Treatise on Pathology*. 4. *On Therapeutics*. 5. *On the Inoculation for the Small-pox*. 6. *On Tumors and Ulcers*. 7. *Origine de la Peste*. 8. *De motu Musculari*. 9. *L'Art de l'Accoucheur*. 10. *De motus Fermentativi*. 11. *Memoire sur la Digestion*. 12. *On the diseases of Women*. The first and last have been translated into English. He died universally regretted, on the 15th of May 1766, in the eighty-second year of his age.

ASTRUM, or ASTRON, a constellation, or assemblage of stars; as distinguished from aster, a single star.

ASTRUT'. On strut. See STRUT.

What good can the great gloton do w^o his bely standing a *strote* like a taber, and his noll toty with drink. *Sir Thos. More*, fol. 98.

Inflated and *astrut* with self conceit,
He gulps the windy diet; and ere long,
Adopting their mistake, profoundly thinks
The world was made in vain, if not for him.

Couper. The Task, book v.

ASTURA, in ancient geography, a town of Italy, in the Campagna di Roma, which had a good harbour. Cicero lost his life in it, and prince Conradin, last heir of the house of Hohenstaufen, was taken prisoner here in 1268.

ASTURIA, an ancient kingdom of Spain, subdued by Augustus emperor of Rome.

ASTURIANS, the brave inhabitants of Asturia, who, along with those of Cantabria, asserted their liberty long after the rest of Spain had submitted to the Roman yoke. So great was their desire of liberty, that, after being closely shut up by the Roman army, they endured the most terrible calamities of famine, even to the devouring of one another, rather than submit to the enemy. At length, however, the Asturians proposed to surrender; but the Cantabrians opposed the measure, and maintained that they ought rather to die sword in hand. Upon this the two nations quarrelled, notwithstanding their desperate situation; and a battle ensuing, 10,000 of the Asturians were driven to the entrenchments of the Romans, whom they begged, in the most moving manner, to receive them on any terms. But Tiberius refusing to admit them into the camp, some of these unhappy people put an end to their lives by falling on their own swords; others, lighting great fires, threw themselves into them, while some poisoned themselves by drinking the juice of a venomous herb. The campaign being closed by the winter, the next year the Asturians summoned all their strength against the Romans; but, after frequent efforts, sometimes in conjunction with the Cantabrians, they were reduced by the imperial armies, and submitted to the Roman power till the subversion of that empire by the Goths.

ASTURIA, or ASTURIAS, anciently the kingdom of Asturia, is now a principality of modern Spain. It is bounded by Biscay on the east, Galicia on the west, Castile and Old Leon on the south, and the sea on the north. Its greatest length is about 120 miles, and its breadth 54. On the south it is separated from Castile and Old Leon by high mountains covered with woods. The province is tolerably fertile, but is thinly inhabited. It has mines of gold, lapis lazuli, and vermilion. The hereditary prince of Spain is styled Prince of the Asturias; the infant Don Henriquez, son of John I. of Castile, being the first who took that title in 1388. This principality is commonly divided into Asturia d'Oviedo, and Asturia de Santillana, so called from their principal towns; the former occupying two-thirds of the principality to the west, and being about thirty Spanish leagues in length, and eighteen in breadth; the latter the other third, sixteen leagues long and twelve broad. The climate of the whole principality is colder than the rest of Spain; but the mountains and hills, though often covered with snow during the whole winter, abound with excellent pastures, and a great variety of fruit trees. Apples are particularly abundant, and a great deal of cyder is made and exported; Spanish America alone has received 28,000 arobas of 25 lb. each yearly. But the most important branch of their agriculture is the breeding of cattle; and their horses have been celebrated for strength from the days of Martial and Silius Italicus. The Asturias contain a bishopric, 668 parishes, 36 religious houses, including 23 monasteries and nunneries, a university, 3 colleges, a royal court of justice, 4 cities, 50 towns, and 3 sea-ports, the principal of which is Gijon, together with several villages; and a population of about 350,000. In more modern history, they are celebrated for having received Pelayo and the other Christians who escaped from the Moors after the battle of Xeres de la Frontera, and who, protected by this mountainous country, bade defiance to, and finally expelled the invaders, laying in these provinces the foundation of the Spanish monarchy. Hence the Asturian nobility and gentry are possessed of some extraordinary privileges, and the inhabitants of the mountain Ancena are still distinguished by the title of 'the illustrious mountaineers.'

ASTURIAS, in zoology, a name by which some authors have called the goshawk.

ASTUTE. Lat. *astutus*; from Gr. *αστυ*, a city. Acute, penetrating, sharp. Applied to the inhabitants of a city who are supposed to be sharp-witted in consequence of having much intercourse with the chicane and craft of mankind, and are therefore prepared to contend with it.

We term those most *astute* which are most versatile.

Sir M. Sandy's Ess. p. 168.

ASTYAGES, son of Cyaxares, the last king of the Medes. He dreamed, that from the womb of his daughter Mandane, married to Cambyses king of Persia, there sprung up a vine that spread itself over all Asia; and she being with child, he resolved to kill the infant as soon as born. Its name was Cyrus; but Harpagus being sent to destroy it, preserved it; which Astyages hearing of long after, he caused Harpagus to eat

his own son. Harpagus, in revenge, called in Cyrus, who dethroned his grandfather, and thereby ended the monarchy of the Medes; the tyrant thus losing his kingdom by the barbarous means he took to preserve it. See *MEDIA* and *PERSIA*.

ASTYANAX, the only son of Hector and Andromache. After the taking of Troy, he was thrown from the top of a tower by Ulysses' orders.

ASTYNOMI, in Grecian antiquity, magistrates in Athens, corresponding to the ædiles of the Romans; they were ten in number. See *ÆDILE*.

ASUNDER. On sunder.

Two indirect lines; the further that they are drawn out, the further they go *asunder*. *Spenser on Ireland.*

So looks the pent up lion o'er the wretch

That trembles under his devouring paws;

And so he walks insulting o'er his prey,

And so he comes to tear his limbs *asunder*.

Shakspeare's Third Part of Henry VI. act i. sc. 5.

The way of Fortune is like the milken way in the skie, which is a meeting or knot of a number of small stars; not seen *asunder*, but giving light together: so are there a number of little and scarce discerned virtues, or rather faculties and customs, that make men fortunate.

Lord Bacon's Essays.

Sense thinks the planets spheres not much *asunder*;
What tells us then, their distance is so far?

Davies.

Greedy hope to find

His wish and best advantage, us *asunder*.

Paradise Lost.

The fall'n archangel, envious of our state,

Seeks hid advantage to betray us worse;

Which, when *asunder*, will not prove too hard,

For both together are each other's guard.

Dryden.

Borne far *asunder* by the tides of men,

Like adamant and steel they meet again.

Dryden's Fables.

All this metallick matter (both that which continued *asunder*, and in single corpuscles, and that which was amassed and concreted into nodules,) subsided.

Woodward's Natural History.

The diversified but connected fabrick of universal justice is well cramped and bolted together in all parts; and depend upon it, I never have employed, and I never shall employ, any engine of power which may come into my hands, to wrench it *asunder*.

Burke.

Upon the whole, there was in this man something that could create, subvert, or reform; an understanding, a spirit, and an eloquence, to summon mankind to society, or to break the bands of slavery *asunder*, and to rule the wilderness of free minds with unbounded authority; something that could establish or overwhelm empire, and strike a blow in the world that should resound through the universe.

Grattan's Character of Lord Chatham.

ASYLA, the plural of ASYLUM. The asyla of altars and temples were very ancient; and likewise those of tombs, statues, and other monuments of considerable personages. Thus, the temple of Diana at Ephesus was a refuge for debtors; the tomb of Theseus for slaves. In order to people Rome, a celebrated asylum was opened by Romulus between the mounts Palatine and Capitoline, for all sorts of persons indiscriminately, fugitive slaves, debtors and criminals of every kind. It had a temple dedicated to the god Asylæus. The Jews had

their asyla; the most remarkable of which were, the six cities of refuge, the temple, and the altar of burnt offerings; which protected those who had incurred the lash of the law, but not for any deliberate crime. But it was customary among the heathens to allow refuge and impunity, even to the vilest and most flagrant offenders; some out of superstition, and others for the sake of peopling their cities. They had an idea, that a criminal who fled to the temple or altar, submitted his crime to the punishment of the gods; and that it would be impiety in man to take vengeance out of their hands. It was by this means, and with such inhabitants, that Thebes, Athens, and Rome, were first stocked. We even read of asyla at Lyons and Vienne, among the ancient Gauls; and there are some cities in Germany, which still preserve this ancient right. On the medals of several ancient cities, particularly in Syria, we meet with the inscription ΑΣΥΛΟΙ, to which is added ΙΕΡΑΙ. The emperors Honorius and Theodosius, granting the like immunities to churches, the bishops and monks soon selected certain tracts or territories, without which they fixed the bounds of the secular jurisdiction; and so well did they manage their privileges, that convents in a little time became a kind of fortresses, where the most notorious offenders were in safety. These privileges at length were extended, not only to the churches and churchyards, but also to the bishops' houses; whence the criminal could not be removed without a legal assurance of life, and an entire remission of the crime. At last these asyla were stripped of most of their immunities. In Great Britain particularly, they have been entirely abolished as protecting criminals, although there are still some privileged places of refuge for debtors, such as the precincts of the royal palaces, the Abbey of Holy-rood-house, Edinburgh, &c.

ASYLUM. Gr. *a*, the privative, and *συλη*, spoil; because it was not lawful to spoil those who fled to a sanctuary.

So sacred was the church to some, that it had the right of an *asylum* or sanctuary. *Ayliffe's Parer.*

But noble dames,

In this *asylum* sojourning awhile,

Trust your own merits, and a guardian god.

Glover's Athenaid, book ii.

The adventurer knows he has not far to go before he will meet with some fortress that has been raised by sophistry for the *asylum* of error. *Hawkesworth.*

ASYLLUS, the gad-fly. See ASYLUS.

ASYMMETRY, } *A*, the privative, and *συμ-*

ASYMMETRAL, } *μετρον*, proportion. Want

ASYMMETROUS. } of symmetry, disproportion.

Quantities compared with respect to such a measure, are by geometers wont to be called *symmetrical* or *asymmetrical*, i. e. commensurable or incommensurable. *Barrow's Mathematical Lectures.*

The *asymmetries* of the brain, as well as the deformities of the legs or face, may be rectified in time.

Grew.

ASYMPTOTE; from *a* priv. *συν*, with, and *πρω*, to fall; which never meet; incoincident. Asymptotes are right lines, which approach nearer to some curve; but which, though they and their curve were infinitely continued, would never meet; and may be conceived as

tangents to their curves at an infinite distance. See CONIC SECTIONS.

ASYNDETON, from the privative *a*, and *συνδew*, I bind together; a figure in rhetoric, implying an omission of words, or a defect of conjunctive particles. The want of such particles represents either the celerity of an action, or the haste and eagerness of the speaker. As, in the celebrated instance, 'veni, vidi, vici,' 'I came, I saw, I conquered.'

AT. From the Latin *ad*. In its abstract sense designating completion, termination, touching the surface by approach.

For all the field was but of sand

As small as men may see at eye

In the desert of Libye.

Chaucer. The House of Fame, b. i. c. 3.

I speke the thingis that I saigh at my fadir; and ye doen the thingis that ye saighen at youre fadir.

Wiclif. Jon. chap. viii. p. 61.

Under pardon,

You are much more at task, for want of wisdom; Than prais'd for harmless mildness. *Shakspeare.*

Others, with more helpful care,

Cried out aloud, Beware, brave youth, beware!

At this he turn'd; and, as the bull drew near, Shunn'd and receiv'd him on his pointed spear.

Dryden.

Their various news I heard, of love and strife, Of storms at sea, and travels on the shore. *Pope.*

ATABALIPA, or ATAHUALPA, the last of the Incas. On the death of his father, in 1529, he succeeded to the throne of Quito, while his brother Huascar obtained the kingdom of Peru. Not long after a disagreement took place, and hostilities commenced betwixt them, in which Huascar was defeated. The Spaniards taking advantage of these disturbances, with Pizarro as their leader, invaded Peru, where they were entertained with no little hospitality by the king and the people; but, instead of making any return for his kindness, they, with their usual treachery held him in captivity. The inca, as a ransom, offered to give the Spaniards a room full of gold, and, when they had got the treasure in their possession, they, with the utmost baseness, burnt the unhappy monarch at the stake, in 1533.

ATABULUS, in physiology, a provincial wind in Apulia, of a dry pinching quality, and very noxious in its effects. The ancient naturalists speak of the Atabulus in terms of horror, on account of the ravages it made among the fruits.

ATABYRIS, a very high mountain in the island of Rhodes, on which, according to Strabo and Diodorus Siculus, stood a temple of Jupiter Atabyris, whose worship a colony of Rhodians carried into Sicily.

ATACAMA, a chain of mountains in South America, which separate Peru from Quito, and where the cold is very violent.

ATACAMA, a province of Peru, bounded on the north by the province of Arica; east by Lipes, Salta, and Tucuman; south by a desert extending to the kingdom of Chili; and west by the South Sea. Its population is under 3000. Its chief town, of the same name, lies in long. W. 69° 30'. lat. S. 23° 30', on a barren spot, about 100 miles from the sea.

ATACAMITE, in mineralogy, a name given to a variety of muriate of copper, found in the

district of Atacama, in minute crystals and fragments.

ATAD, a Canaanite, rendered memorable by his threshing-floor, Gen. 1. 10. See ABEL-MIZRAIM.

ATALANTA, in ancien. geography, an island in the Euripus of Eubœa, near the Locri Opuntii, said to have been originally a city of the Locri, but torn from the continent in the time of an earthquake, and during an eruption of mount Ætna; in the fourth year of the ninety-third Olympiad, in the reign of Artaxerxes-Mnemon.

ATALANTA, in fabulous history, the daughter of Schœneus, king of Scyros. Being resolved against marriage, and at the same time very swift of-foot, she, to get rid of her numerous suitors, declared that she would marry none but the man who was willing to risk his life for her, by striving to outrun her, and to forfeit it if he failed. This several attempted and suffered accordingly. But Hippomenes, being furnished by Venus with three golden apples, dropt them at proper distances during the race, and while she stooped to gather them, gained both the race and the princess. The goddess Venus being enraged at the ingratitude of Hippomenes, who never performed the vow he had made to erect a temple to her at Scyros, changed both him and Atalanta into lions.

Another ATALANTA received from Meleager, who was enamoured of her, the skin and head of the Caledonian boar, in testimony of her skill in having first wounded the animal. This roused the jealousy of Toxeus and Plexippus, his uncles, who endeavoured to strip Atalanta of her honorable spoil. Meleager killed them in defence of her right; and his mother Althœa, irritated by the death of her brothers, committed to the flames the charmed brand upon which the life of Meleager depended. This second Atalanta was the daughter of Jasus and Clymene.

ATALANTA, in entomology, a species of European papilio, of which a variety is also found in America. The wings are black, indented, and spotted with white; a red band across the anterior pair; border of the posterior pair of the same color. It is sometimes called the red admirable butterfly, and by the French Atalante.

ATALAYA DE AEAGOUTA, a town in Portuguese Estremadura, district of Thomar, with the title of county, and between 1300 and 1400 inhabitants, eighteen miles north-west of Lishon.

ATALAYA SORTEIHA, a town of Portugal, in the province of Beira, thirteen miles north-east of Castel Branco.

ATALAYAS, SANTIAGO DE LAS, the capital of the province of San Juan de los Llanos, in the kingdom of Granada. It contains 400 householders, and is nine leagues from the city of Pore.

ATANARI, a considerable river of New Granada, which enters the Mota.

ATANTA, in botany, a name given by the people of Guinea to a kind of sumach, called, by Pétiver, rhus Guineense trifoliatum scabium, from its being trifoliate, and having rough and serrated leaves. They give it as a restorative boiled in water.

ATAPUERA, a town of Spain, in Old Castile, near Burgos. In 1053, a battle was fought here between Don Garcia, king of Navarre, and

his brother Don Ferdinand, in which the former was defeated and slain.

ATARAXIA, ATARAXY, ἀταραξία. Exemption from vexation; tranquillity. The sceptics, says Glanville, affected an indifferent equiponderous neutrality, as the only means to their ataraxia, and freedom from passionate disturbances.

ATARGATIS FANUM, the temple of the goddess Atergatis, in Bambyce, which was extremely rich. Crassus, in his march against the Parthians, spent several days in weighing the treasure.

ATARNEA, or ATARNYA, an ancient town of Mysia, situated between Adramyttium and Pitane, memorable for the marriage of Aristotle with the sister of Hermias, the prince of it.

ATAULFUS, the first king of the Goths in Spain, established his government there, about A. D. 404, and died, A. D. 416. See SPAIN.

ATAXY, from a negative, and ταξις, order, the want of order. With physicians, it signifies irregularity of crises and paroxysms of fevers.

Neither is there any *ataxy* to be feared in bringing in this distinction, betwixt pastors and the flock.

Bp. Hall's Polemical Works.

ATCHE, in commerce, the smallest silver coin current in Turkey, worth about one-third of a penny sterling.

ATCHIEVEMENT, or ACHIEVEMENT, vulgarly called HATCHMENT. Armorial bearings in front of the houses of deceased persons.

ATCHIEVEMENT, in heraldry, denotes the arms of a person or family, together with all the exterior ornaments of the shield, as helmet, mantle, crest, scrolls, and motto, together with such quarterings as may have been acquired by alliances, all marshalled in order.

ATE; from *araw*, to hurt; the goddess of mischief, in the mythology. She was daughter of Jupiter, and cast down from heaven at the birth of Hercules. For Juno having deceived Jupiter, in causing Euristheus to be born before Hercules, Jupiter expressed his resentment against Ate, as the author of that mischief, and threw her headlong from heaven to earth, swearing she should never return thither again. Homer. II. xix. 125. Her being the daughter of Jupiter means, according to mythologists, that no evil happens to us but by the permission of Providence; and her banishment to earth the terrible effects of divine justice among men.

ATEGAR; from the Saxon *aeton*, to throw, and *gar*, a weapon; a weapon among the Saxons, which seems to have been a hand-dart.

ATEGUA, or ATTEGUA, an ancient town of Spain, placed by some in the road from Antiquara, now Antequera, to Hispalis, or Seville; by others, near Alcalá Real. It was situated near the river Flumen Salsum, or Salsusa. Pompey, having passed this river, encamped between Ucubis and Ategua, to oblige Cæsar to raise the siege of the latter place; but it was taken in his presence.

ATELIA, an exemption from taxes, or other burdens, is particularly used in some ancient laws, for an exemption from offices granted to the Egyptian clergy by Constantius.

ATELIA, an ancient town of Campania in Italy, between Capua and Neapol's. The ruins

are still to be seen about eleven miles from the modern Aversa.

ATELLANÆ FABULÆ, ATELLANI LUDI, a species of farce, so named from Atella, called also Osci, from their inventor, in whose territory Atella lay. They were generally interlarded with much ribaldry and buffoonery, and sometimes were exordia, or interludes, presented between the acts of other plays. The actors in these farces were not reckoned among the common players, nor deemed infamous; but retained the rights of their tribe, and might be enlisted for soldiers, the privilege only of free men.

ATEMPO GIUSTO, in music, signifies to sing or play in an equal, true, and just time.

ATENA, a town of Italy, in Naples, near the Negro, twelve miles north-west of Marsico, and twenty-two north of Policastro.

ATER, in conchology, a species of mytilus, described in Molin. Hist. Chili, p. 177, and said to be frequent on the shores of that country: also a species of strombus found in the boggy parts of the island of Amboyna.

ATER, in entomology, 1. a species of dermestes found in the neighbourhood of Upsal. 2. A species of hydrophilis, a native of Europe. 3. A species of byrrhus that inhabits Germany. 4. A species of tenebrio found in Europe. 5. A species of carabus that inhabits Denmark. 6. A species of cerambyx (*Callidium*, Fabr.) found in the environs of Venice. 7. A species of gryllus (*Acheta*, Fab.) that inhabits Surinam. 8. A species of cimex.

ATER, in natural history, a species of anguis; also a species of limax, slug or snail.

ATER, in ornithology, a species of falco; also a species of psittacus.

ATERGATIS, in mythology, a goddess of the Syrians and Parthians, supposed to be the mother of Semiramis, and called Derceto by the Greeks. She was represented with the face and breasts of a woman, but the rest of her body resembled a fish. Vossius makes the name Phœnician, from addir-dag, the great fish; and says it signifies, without fish; whence he conjectures that the victories of this deity abstained from fish.

ATERNUM, in ancient geography, 1. a town of Lucania in Italy, now called Aterni. 2. A town in the territory of the Piceni, now called Pescara, a port town of Naples, on the Adriatic.

ATERRIMA, in conchology, a species of nerita, figured by Chemnitz.

ATERRIMA, in entomology, 1. a species of blattæ. 2. A new British species of chrysomela, described by Mr. Marsham, Ent. Brit.

ATERRIMUS, 1. a species of curculio, very common in Europe; black, with the wing-cases shining. Linn. Fn. Sv. Fabr., &c. 2. A species of eribus. 3. A species of elater, found in the north of Europe. 4. A species of cimex (rotundatus, see.) that inhabits Spain.

ATERRIMUS, in ornithology, the specific name of the great black cockatoo of New Holland.

ATESTE, a town in the territory of Venice in Italy, now called Este.

ATH, or **ETH**. See **ETH**.

ATH, ATHA, or ATHF, among our Anglo-Saxon ancestors, signifies an oath, especially that taken

by way of purgation. In this sense, we meet with breaking of ath, privilege of ath, atha, or ordela.

ATHABOLI, or **AGASTOBOLI**, a town of Turkey in Europe, on the Black Sea, in the extensive province of Romania, sixty-eight miles north-east of Adrianople. Long. 27° 39' E., lat. 42° 27' N.

ATHALARIC, the grandson of Theodoric, and the second king of the Ostrogoths in Italy, succeeded A. D. 526, and reigned along with his mother Amalasuha, about eight years. They both died A. D. 534.

ATHALIAH, **עַתְלִיָּה**, Heb. i. e. the time of the Lord; the daughter of Ahab king of Israel, by Jezebel, and wife of Jehoram king of Judah. See 2 Chron. xxi. 10, and xxiii. 12.

ATHAMADULET, or **ATHEMADAULET**, the prime minister of the Persian empire. He is great chancellor of the kingdom, president of the council, superintendent of the finances; and has the charge of all foreign affairs. He is in effect viceroy of the kingdom.

ATHAMANTA, Spigel, in botany, a genus of the digynia order, and pentandria class of plants, ranking in the natural method under the fourth order, umbellatæ. The fruit is oblong and striated; and the petals are inflected and emarginated. Of this genus Linnaeus enumerates nine species: but none of them merit particular notice; except the *Cretensis*, or *Daucus Creticus*, which grows wild in the Levant and the warmer parts of Europe. The leaves are irregularly disposed, and formed like those of fennel. The flower-stalk rises about two feet high, sending out many branches, terminated at the top by compound umbels, composed of nearly twenty small ones. The seeds have a warm biting taste, with an agreeable aromatic smell. They are kept in the shops as a carminative; but are little used in practice.

ATHANASIA, Goldilocks, in botany, a genus of the polygamia æqualis order, and syngenesia class of plants; ranking in the natural method under the forty-ninth order, compositæ discoides. The receptacle is chaffy; the pappus chaffy and very short, and the calyx imbricated. There are twenty species, all tender plants except one; and none of them possessed of much beauty.

ATHANASIA, in ancient medicine, an epithet given to a kind of antidotes, supposed to have the power of prolonging life, even to immortality. In the Augustan dispensatory we still find a medicine under the appellation of *athanasia magna*, recommended against dysenteries and hæmorrhages.

ATHANASIA, in botany, is used by some authors for tansy.

ATHANASIAN CREED; a formulary, or confession of faith, long supposed to have been drawn up by Athanasius bishop of Alexandria, in the fourth century, to justify himself against the calumnies of his Arian enemies; but now generally allowed among the learned not to have been his. Dr. Waterland ascribes it to Hilary bishop of Arles, for the following among other reasons: 1. Because Honoratus of Marseilles, the write.

of his life, tells us, that he composed an Exposition of the Creed; a more proper title for the Athanasian, than that of Creed simply, which it now bears. 2. Hilary was a great admirer and follower of St. Austin; and the whole composition of this creed is in a manner upon St. Austin's plan, both with respect to the trinity and the incarnation. 3. It is agreeable to the style of Hilary, as far as we can judge from the little that is left of his works. About A. D. 570, it became so famous as to be commented upon; but, for several years after, it had not acquired the name of Athanasian, but was simply styled the catholic faith. This creed obtained in France about A. D. 850, and was received in Spain and Germany about 100 years later. As to our own country, we have clear proofs of its being sung alternately in our churches in the tenth century. It was in common use in some parts of Italy, particularly in the diocese of Verona, about A. D. 960, and was received at Rome about 1014. As to the Greek and oriental churches, it has been questioned whether any of them ever received this creed at all: with regard to its matter, it is given as a summary of the true orthodox faith, and a condemnation of all heresies, ancient and modern. Unhappily, however, it has proved a fruitful source of unprofitable controversy and unchristian animosity even down to the present time.

'The account given of Athanasius's creed,' says archbishop Tillotson, in a letter written from Lambeth, Oct. 23, 1694, to a right reverend prelate, 'seems to me no wise satisfactory: I wish we were well rid of it.' Bishop Taylor, in his Liberty of Prophesying, sect. ii. says, 'If it were considered, concerning Athanasius's creed, how many people understand it not, how contrary to natural reason it seems, how little the scripture says of those curiosities of explanation, and how tradition was not clear on his side for the article itself, much less for those forms and minutes; it had not been amiss if the final judgment had been left to Jesus Christ: and indeed to me it seems very hard to put uncharitableness into the creed, and so to make it become as an article of faith.' 'It certainly is to be lamented,' says Dr. Tomline, the present bishop of Worcester, in his Elements of Christian Theology, vol. ii. p. 220, 'that assertions of so peremptory a nature,' referring to the damnatory clauses, 'unexplained and unqualified, should have been used in any human composition.' 'I am ready to acknowledge,' p. 222, 'that, in my judgment, notwithstanding the authority of former times, our church would have acted more wisely, and more consistently with its general principles of mildness and toleration, if it had not adopted the damnatory clauses of the Athanasian creed. Though I firmly believe that the doctrines themselves of this creed are all founded on scripture, I cannot but conceive it to be both unnecessary and presumptuous to say, that 'except every one do keep them whole and undefiled, without doubt he shall perish everlastingly.' Dr. Horsley, late bishop of St. Asaph, avowed a similar opinion.

ATHANASIUS, St. bishop of Alexandria, and one of the most violent opponents of the Arians,

was born in Egypt. He followed St. Alexander to the council of Nice, in 325, where he disputed against Arius, and the following year was made bishop of Alexandria; but, in 335, was deposed by the council of Tyre: when, having recourse to the emperor Constantine, the Arian deputies accused him of having hindered the exportation of corn from Alexandria to Constantinople; on which the emperor, without suffering him to make his defence, banished him to Treves. The emperor, two years after, ordered him to be restored to his bishopric: but, on his return to Alexandria, his enemies brought fresh accusations against him, and chose Gregory of Cappadocia to his see; which obliged Athanasius to go to Rome, to reclaim it of pope Julius. He was there declared innocent, in a council held in 342, and in that of Sardica, in 347, and two years after was restored to his see by order of the emperor Constans; but, after the death of that prince, he was again banished by Constantius, on which he retired into the deserts. The Arians then elected one George in his room; who being killed, in a popular sedition under Julian, in 360, Athanasius returned to Alexandria, but was banished under Julian, and restored to his see under Jovian. He addressed to that emperor a letter, in which he proposed, that the Nicene creed should be the standard of the orthodox faith, and condemned those who denied the divinity of the Holy Ghost. He was also banished by Valens, in 367, and afterwards recalled. He died on the 2d of May, 373. His works principally contain a defence of the mystery of the Trinity, and of the incarnation and divinity of the Word and Holy Spirit. There are three editions of his works which are esteemed; that of Commelin, printed in 1600; that of Peter Nannius, in 1627; and that of father Montfaucon.

ATHANATI, i. e. immortals; from *a*, privative, and *θανος*, death; a body of cavalry, among the ancient Persians, consisting of 10,000 men, always complete, because when any one of them died another was immediately put in his place.

ATHANOR. Chemists have given this name to a furnace so constructed, that it can always maintain an equal heat, and lasts a long time, without addition of fresh fuel. The body of the athanor has nothing in it particular, and is constructed like ordinary furnaces. But at one of its sides, or its middle, there is an upright hollow tower, which communicates with the fire-place, by one or more sloping openings. This tower ought to have a lid, which exactly closes its upper opening. When the athanor is to be used, as much lighted coal is put in the fire-place as is judged necessary, and the tower is filled to the top with unlighted fuel. The tower is then to be exactly closed with its lid. As fast as the coal in the fire-place is consumed, that in the tower falls down and supplies its place. As the coal contained in the tower has no free communication with the external air, it cannot burn, till it falls into the fire-place. The athanor being much celebrated and used by ancient chemists, has been particularly described by many authors, and was formerly found in all laboratories. At present, this furnace is much less employed, and even neglected. The reason is, that all the

ancient chemists were in search of the art of making gold; and being excited by this powerful motive, and confident of success, they spared no trouble or expense to accomplish this design.— They undertook, without hesitation, operations which required great length of time, and unre-mitted heat. Whereas now, these alluring hopes having vanished, the cultivators of chemistry have no other view than to extend and perfect the theory of this essential part of natural philo-sophy. This motive, although undoubtedly much nobler than the former, seems, however, to be less powerful over most men. For now, all long and laborious operations, whence chemistry might receive great advantages, are neglected, as being tiresome and disgusting. There is, in fact, a considerable difference betwixt the hope of explaining a philosophical phenomenon, and that of obtaining an ingot of gold capable of produc-ing many others. Hence the instruments employed in long operations, and particularly the athanor, are now much neglected; and also, because the fuel in the tower is apt to stick there, or fall down at once in too great quantity. The lamp furnace, which is a true athanor, may be success-fully employed in operations which do not re-quire much heat.

ATHAPESCOW, a lake in the north-west of North America, and fifty-ninth degree of north latitude, so called from a tribe of Indians inha-biting its banks. It is contiguous to the Lake of the Hills, and has now become so shallow, that, according to Mackenzie, it will in time be probably converted into a swamp.

ATHARER, in astrology, a term used when the moon is in the same degree and minute with the sun.

ATHBOY, a town of Ireland, in the county of Meath, situated on a stream of the same name. It was a borough, which returned members to the Irish parliament before the union. Three fairs are held here annually. Distant twenty-nine miles north-west of Dublin.

ATHEE, a town of France, in Anjou, with 260 houses, belonging to the arrondissement of Chateau-Gontier, in the department of Mayenne. It lies on the river Oudon, five leagues S. S. W. of Laval.

ATHIF, a town of France, in the department of the Indre and Loire, arrondissement of Tours, on the left bank of the Cher, with 255 houses, three leagues south-west of Amboise.

ATHEISM ,	} A, privative, <i>ἄθεος</i> , God; without God. One of its significations is illustrated by the following citation from St. Paul's Epistle to the Ephesians, <i>Ἄθεοι ἐν τῷ κόσμῳ</i> , without God in the world.
ATHEIST , <i>n. & adj.</i>	
ATHEISTICAL ,	
ATHEISTICALLY ,	
ATHEISTICNESS ,	
ATHEISTICK ,	
ATHEISTE ,	
ATHÉOUS ,	

God never wrought miracles to convince *atheism*, because his ordinary works convince it. *Bacon*.

Nor stood unmindful Abdiel, to annoy
The *atheist* crew. *Milton. Paradise Lost*.

Thy Father, who is holy, wise, and pure,
Suffers the hypocrite, or *atheous* priest,

To tread his sacred courts. *Paradise Regained*.

Men are *atheistical*, because they are first vicious; and question the truth of Christianity, because they hate the practice. *South*.

Is it not enormous, that a divine, hearing a great sinner talk *atheistically*, and scoff profanely at religion, should, instead of vindicating the truth, tacitly approve the scoffer? *Id*.

Though he were really a speculative *atheist*; yet, if he would but proceed rationally, he could not how-ever, be a practical *atheist*, nor live without God in this world. *Id*.

I entreat such as are *atheistically* inclined, to con-sider these things. *Tillotson*.

It is the common interest of mankind, to punish all those who would seduce men to *atheism*. *Id*.

Atheist, use thine eyes;
And, having view'd the order of the skies,
Think (if thou canst) that matter, blindly hurl'd
Without a guide, should frame this wondrous world. *Creech*.

No *atheist*, as such, can be a true friend, an affec-tionate relation, or a loyal subject. *Bentley*.

Lord, purge out of all hearts profaneness and *atheisticalness*. *Hammond's Fundamentals*.

This argument demonstrated the existence of a Deity, and convinced all *atheistick* gainsayers. *Ray on the Creation*.

Chester, civilized as well as Wales, has demon-strated, that freedom and not servitude is the cure of anarchy; as religion, not *atheism*, is the true re-medy for superstition. *Burke*.

ATHEISM, absurd and unreasonable as it is, has had its votaries and martyrs. In the seven-teenth century, Spinosa, a foreigner, was its noted defender. Lucilio Vanini, an Italian, a native of Naples, publicly taught atheism in France, about the beginning of the seventeenth century; and being convicted of it at Toulouse, was condemned and executed.

An **ATHEIST** may be defined, a person who does not believe in any thing superior to the material world. Many people both ancient and modern, have pretended to be, or have been reckoned, atheists; but it is justly questioned whether any man ever seriously adopted such a principle. These pretensions, are often, indeed, founded on pride and affectation. Such motives, together with an honest indignation against the imposi-tions and intolerance of superstition and priest-craft (which had so often deluged France with blood), seem to have co-operated to produce that extraordinary moral phenomenon, exhibited in the French Convention, of several of the lead-ing members openly avowing themselves atheists; in consequence of which the whole nation was absurdly branded with atheism. Cicero, however, represents it as a probable opinion, that they, who apply themselves to philosophy, believe there are no gods. This must doubtless be meant of the academic philosophy, to which Cicero himself was attached, and which taught to doubt of every thing. On the contrary, the Newtonian philo-sophers, continually recur to a Deity, whom they always find at the head of their chain of natural causes. Among the modern philosophers, who have been the principal advocates for the existence of a Deity, are Sir Isaac Newton, Boyle, Cheyne, Nieuwentyt, &c. To which may be added many others, who, though of the clergy, yet have distinguished themselves by their philosophical pieces in behalf of the existence of a God; e. g. Derham, Bentley, Whiston, Ray, Samuel and John Clarke, Fenelon, &c. So true is that say-ing of Lord Bacon, that though a smattering of

philosophy may lead a man into atheism, a deep draught will certainly bring him back again to the belief of a God and Providence; agreeably to what the poet observes of learning in general:

‘A little learning is a dangerous thing;
Drink deep, or taste not the Pierian spring.’

Archbishop Tillotson justly observes that speculative atheism is unreasonable on five accounts: 1. Because it gives no tolerable account of the existence of the world: 2. It does not give any reasonable account of the universal consent of mankind in this comprehension, that there is a God: 3. It requires more evidence for things than they are capable of giving: 4. The atheist pretends to know what no man can know: 5. Atheism contradicts itself. Under the first of these he advances the following arguments: ‘I appeal to any man of reason whether any thing can be more unreasonable than obstinately to impute an effect to chance, which carries in the very face of it all the arguments and characters of a wise design and contrivance. Was ever any considerable work, in which there was required a great variety of parts, and a regular and orderly disposition of those parts, done by chance? Will chance fit means to ends, and that in ten thousand instances, and not fail in any one? How often might a man, after he had jumbled a set of letters in a bag, fling them out upon the ground before they would fall into an exact poem; yea, or so much as make a good discourse in prose? And may not a little book be as easily made as the great volume of the world? How long might a man be in sprinkling colors upon canvass with a careless hand, before they would happen to make the exact picture of a man? And is a man easier made by chance than his picture? How long might twenty thousand blind men, who should be sent out from several remote parts of England, wander up and down before they would all meet upon Salisbury plain, and fall into rank and file in the exact order of an army? Yet this is much more easy to be imagined than how the innumerable blind parts of matter should rendezvous themselves into a world. A man that sees Henry the Seventh’s chapel at Westminster, might with as good reason maintain (yea, with much better, considering the vast difference betwixt that little structure and the huge fabric of the world) that it was never so contrived or built by any means, but that the stones did by chance grow into those curious figures, into which they seem to have been cut and graven; and that upon a time (as tales usually begin) the materials of that building, the stone, mortar, timber, iron, lead, and glass, happily met together; and very fortunately ranged themselves into that delicate order in which we see them now, so close compacted, that it must be a very great chance that parts them again. What would the world think of a man that should advance such an opinion as this, and write a book for it? If they would do him right, they ought to look upon him as mad, but yet with a little more reason than any man can have to say that the world was made by chance, or that the first men grew out of the earth as plants do now. For can any thing be more ridiculous, and against all

reason, than to ascribe the production of men to the first fruitfulness of the earth, without so much as one instance and experiment, in any age of history, to countenance so monstrous a supposition? The thing is, at first sight, so gross and palpable, that no discourse about it can be more apparent. And yet, these shameful beggars of principles give this precarious account of the original of things; assume to themselves to be the men of reason, the great wits of the world, the only cautious and wary persons that hate to be imposed upon, that must have convincing evidence for every thing, and can admit of nothing without a clear demonstration for it.’

ATHELING, ADELING, EDLING, ETHLING. or **ETHELING**; from *æthel*, noble, Saxon; a title among the Anglo-Saxons, properly belonging to the heir apparent to the crown. This appellation was first conferred by king Edward the Confessor on Edgar, to whom he was great uncle, when, being without any issue of his own, he intended to make him his heir. See **EDGAR**.

ATHELNEY, an island of England, in the county of Somerset, formed by the junction of the rivers Tone and Parret, a few miles below Taunton. Alfred took refuge here while the country was overrun by the Danes, and is said to have built an abbey on the spot. Many antiquities were dug up in 1674

ATHELSTANĒ, a Saxon king of England, natural son of Edward the Elder, and grandson of the great Alfred. He succeeded in 925, and reigned sixteen years. There was a remarkable law passed by this prince, which shows his just sentiments of the advantages of commerce, as well as the early attention paid to it in this country: viz. that any merchant who made three voyages on his own account beyond the British Channel, should be entitled to the privilege of a thane, or gentleman.

ATHELSTANE, king of Northumberland, or, according to Buchanan, a Danish chief, who obtained a grant of that country from king Alfred, flourished about the beginning of the ninth century; and, carrying on a predatory war in Scotland, was killed in battle by Hungus, king of the Picts, at the village since named from him Athelstaneford, near the rivulet called Lugdown Burn, which is said to be a corruption of Rug Down, and to have taken its name from the circumstance of Athelstane being rugged down, or pulled from his horse, in the battle.

ATHELSTANEFORD, a village and parish of Scotland, in the county of Haddington. It was the birth-place of Blair, the author of *The Grave*; and here Mr. Home was settled as parish minister, but was obliged to relinquish the living in consequence of having written the tragedy of Douglas. Distant two miles from Haddington, seventeen from Edinburgh, east.

ATHENA, in the ancient physic, a plaster or liniment commended against wounds of the head and nerves, of which we find descriptions given by Oribasius, Ælius, and Ægineta.

ATHENÆA, a feast of the ancient Greeks held in honor of Minerva, whom they called *Αθηνη*. They were afterwards called *Παναθηναæ*.

ATHENÆUM, in antiquity, a public place

wherein the professors of the liberal arts held their assemblies, the rhetoricians declaimed, and the poets rehearsed their performances. These places, of which there were a great number at Athens, were built in the manner of amphitheatres, and encompassed with seats called *cunei*. The three most celebrated Athenæ were those at Athens, at Rome, and at Lyons; the second of which was built by the emperor Adrian.

ATHENÆUS, a Greek grammarian, born at Naucratis in Egypt, in the third century, one of the most learned men of his time. Of all his works we have none extant but his *Deipnosophis*, i. e. the sophists at table; there is a great fund of facts and quotations in this work, which render it very agreeable to admirers of antiquity, as they are nowhere else to be met with.

ATHENÆUS, a mathematician, who wrote a treatise on mechanics, which is inserted in the works of the ancient mathematicians, printed at Paris in 1693, in folio, in Greek and Latin.

ATHENÆUS, a physician, born in Cilicia, contemporary with Pliny, and founder of the pneumatic sect. He taught that the fire, air, water, and earth, are not the true elements, but that their qualities are, viz. heat, cold, moisture, and dryness; and to these he added a fifth element which he called spirit, whence his sect had their name, Pneumatics.

ATHENAGORAS, an Athenian philosopher, who flourished about the middle of the second century; and was equally remarkable for his zeal for Christianity, and his great learning; as appears from the Apology which he addressed to the emperors Aurelius Antoninus and Lucius Commodus; as well as from another work still extant upon the Resurrection. They are both written in a style truly Attic.

ATHENATORIUM, among chemists, a thick glass cover placed on a cucurbit, having a slender umbo, or prominent part, which enters like a stopple, within the neck of the cucurbit.

ATHENE; *Ἀθηνῆ*, Greek; the name given by the Greeks to Minerva. See **MINERVA**.

ATHENIPPUM, in the ancient physic, a collyrium commended against divers diseases of the eyes; thus denominated from its inventor Athenippus. It is described by Scribonius Largus and Gorræus. Galen mentions another athenippum, of a different composition, by which it appears that this was a denomination common to several collyriums.

ATHENODORUS, a famous stoic philosopher, born at Tarsus, who went to the court of Augustus, and was made by him tutor to Tiberius. Augustus had a great esteem for him, and found him by experience a man of virtue and probity. He was accustomed to speak very freely to the emperor. Before he left the court to return home, he warned the emperor not to give himself up to anger, but, whenever he should be in a passion to rehearse the twenty-four letters of the alphabet before he resolved to say or do any thing. He did not live to see his bad success in the education of Tiberius.

ATHENOPOLIS, a town of the Massilienses, an ancient nation of Gaul, conjectured to be the same with Telo Martius, now Toulon.

ATHENRY, a village of Ireland, in the county of Galway, formerly a borough, and a walled town. In the year 1315 a battle was fought near this town between the English and Irish, in which the latter was defeated. In 1599 the Irish put all the inhabitants to the sword. Distant ten miles east of Galway, ninety-one from Dublin.

A T H E N S.

ATHENS, in geography and ancient history, a celebrated kingdom of ancient Greece, the capital of Attica, situated 100 miles N. E. of Lacedæmon and 320 S. by W. of Constantinople. It is at present the chief town of Livadia, a province of the Turkish empire, and is seated in the Gulf ofægæa, Lon. 23° 37' E. lat. 38° 5' N.

ORIGIN AND ANCIENT NAME.—The kingdom of Attica received the name of Ogygia, from Ogyges, commonly placed 1536 years before Christ; but Athens is scarcely mentioned in history till some time after the days of Cecrops, an Egyptian by birth, supposed to be contemporary with Moses, and affirmed by the Greeks to be the first builder of cities. This leader who appears to have either founded or new modelled the Acropolis, or ancient city, under the name of Cecropia, placed himself at the head of it, and introduced from Sais in Egypt, the worship of Neith, adopted by the people under the name of *Ἀθηνῆ*. In the early ages of Greece, that which was afterwards called the citadel, was the whole city, and called Polis, or 'the city,' by way of eminence.

ALTERATION OF NAME.—In the reign of Erichthonius it lost the name of Cecropia, and acquired that of Athens, from *Ἀθηνῆ*, the Greek

name of the goddess Minerva, the Neith of the Egyptians already mentioned, who was esteemed its protectress. This old city was seated on the top of a rock in the midst of a large and pleasant plain, which, as the number of inhabitants increased, became full of buildings; which induced the distinction of Acropolis and Catopolis, i. e. of the upper and lower city. The extent of the citadel was sixty stadia; it was surrounded by olive trees, and fortified with a strong palisade; in succeeding times it was encompassed with a strong wall, in which there were one very large and eight small gates.

ORIGINAL SUCCESSION AND GOVERNMENT.—The successors of Cecrops are but imperfectly known, but, according to the most ancient traditions, they were 1. Amphictyon; 2. Erectheus I. the same as Erichthonius, the place of whose interment is still called Erichtheimm. It was this prince who raised an image of Minerva made of olive wood in the Cecropia, and also in honor of the goddess instituted festivals called Athenæa, to be celebrated by the twelve Attic cities. To him succeeded 3. Pandion I. 4. Erectheus II. 5. Ægeus. 6. Theseus. The last of whom established the Prytaneum, a court of judicature common to all Attica; also the Panathenæa,

sacred festivals to be observed by all the provinces in the Erechtheum every five years. His wise government increased the power and population of Athens, and finally, about the year B. C. 1300, concentrated the other eleven cities of Attica under one general government.

INTRODUCTION OF PELASGI, AND RISE OF ATHENIAN GREATNESS.—The Pelasgi came to Athens from the North B. C. 1192, to whom those beautiful specimens of polygonal architecture are ascribed, which are found in the ancient fortresses of Greece and Italy, consisting of irregular blocks carefully adjusted to each other, without cement, whereas the Cyclopean, with which it has been frequently confounded, is composed of masses laid together and the interstices filled up with smaller stones.

Next to the Pelasgi, Athens stands indebted for much of her early grandeur to Pisistratus, who, with his sons, founded a public library and two magnificent temples, one to Jupiter Olympus, the other to Apollo Pythias, besides which he collected and edited the works of Homer.

INVASION OF XERXES AND RE-BUILDING OF ATHENS.—Athens was now rising in population and importance; possessed of considerable maritime ascendancy, together with an extent of territory and influence beyond any other state in Greece, Sparta excepted, and the invasion of Xerxes served to raise her to the pinnacle of military glory. It is true the Persians at first were successful in burning and destroying the ancient city founded by Cecrops; but, after their shameful defeat at Thermopylæ, the city of Athens rose from its ruins on an enlarged and improved scale, the queen of empire, enriched by the resources of the invasion, dignified by a naval superiority, by which she commanded the islands of the Archipelago, together with the colonies of Asia, Macedonia, and Thrace, embellished by the hand of Minerva, who seems to have employed herself the fifty years intervening between the victory of Salamis and the Peloponnesian war, to beautify the city of her residence; her ancient Cecropian monuments yet remaining upon the Acropolis.

SURVIVES THE PELOPONNESIAN WAR.—Themistocles restored the military works of the city, and fortified it as before. Cimon erected the Temple of Theseus, the Stoæ, the Pœcile, the Dionysian Theatre, the Gymnasia, together with the ornaments of the Academy and the Agora. Pericles conferred upon it the Odeum, the Parthenon, and the Propylæa, and numerous other works, rendering it the wonder of nations. The superb glory of Athens was little injured by the war of Peloponnesus. The defeat of Ægospotami, it is true led to the destruction of the walls of Piræus, but these were shortly restored, and so skilful was Minerva that defeats as well as victories seemed to raise the political importance, and enrich the site of her favorite capital.

RAVAGES OF PHILIP OF MACEDON.—The rise of Macedon seemed however to eclipse the glory of Athens, and her alliance with Rome was the first political blow that tended to the real injury of this ancient city. Philip of Macedon invested her before her allies could come to her succour, and as the city was too well fortified to be taken

easily, he ravaged the suburbs, overthrew the temples, shrines, images, and tombs; broke the marbles which were too precious to yield to the influence of fire; the Cynosarges and the Lycæum, all the favorite retreats of pleasure and devotion were alike felled by the arm of the destroyer.

SIEGE BY SYLLA.—About 84 years B. C. during the Mithridatic war, the Roman Sylla resolved upon the conquest of Athens, and employed all Greece with her arms and treasures, to aid his design. He plundered Epidaurus and Olympia, carried away the precious deposits of Delphi, felled the groves of the Academy and the Lycæum. By means of an ill-fortified wall near Heptachalcos he passed the sacred gates at midnight, and the streets of the Cerameicus are said to have run with blood. The city however suffered little, but the destruction of the Piræan fortifications and the arsenal of Philo prevented the re-assumption of maritime power, and with that fell for ever the political importance of Athens. (Plutarch, in vitâ Syllæ). As a school of science and art, Athens nevertheless maintained her dignity among enlightened nations, and foreigners from all parts resorted there to attend the lectures of her philosophers.

SCIENCE AND ARCHITECTURE.—The Romans whose taste in some respects was formed upon the Grecian models, added considerably to the embellishment of the city. Julius Cæsar erected the Propylæa of the new Agora nearly at his own expense. Statues were erected to Brutus and Cassius by the friends of those distinguished Romans. Antony endowed the capital with numerous public gifts and a large accession of insular territory; nor were Augustus and other illustrious personages in that powerful empire remiss in testifying their friendship for the city of Minerva, and some of them were even initiated into the Eleusinian mysteries (for the nature of which see ELEUSINIA.) Hadrian, on his elevation to the imperial dignity, was one of the greatest benefactors Athens enjoyed after the overthrow of her civil hierarchy. He finished the temple of Jupiter Olympius, which Pisistratus had begun ages before, and such was its beauty, costliness, and magnitude, that it was considered the glory of Athens; superb beyond any other structure in Greece. The temple of the winds, more properly called the Honologium, in the Agora, was the benefaction of Andronicus Cyrrhestes. A new theatre was raised by Agrippa, and another was shortly afterwards erected at the foot of the Acropolis by Herodes Atticus, the ruins of which are yet remaining. The casing of the seats of the stadium with pentelic marble, is attributed to the generous profusion of the same illustrious individual.

SPLENDOR UNDER THE ANTONINES.—In the Antonine age Athens enjoyed its greatest splendor. It had been enriched by the accumulated magnificence of six centuries. The works of the age of Pericles, according to Plutarch, retained the freshness of modern buildings, and a bloom was diffused over them, which preserved their aspect untarnished. Athens, in a remarkable manner escaped the ravages and plunder which

followed the conquest of Greece, and the still more formidable dilapidations of time itself. She sat supreme amid the convulsions of states and changes of governments, rather contributing than otherwise to the imperial grandeur. Having pursued the history of Athens up to the zenith of her glory, we shall present the reader with a brief description of that eminent seat of learning and politeness, as she existed in her prosperous ages.

APPEARANCE AND HARBOURS.—Seated upon a gulf, Athens, commanding three harbours surrounded by dock-yards and buildings, forming a continued town more extensive than Athens itself. The first of these was the Piræus, the present *Δράκων* of the Greeks, the *Aslân Limâni* of the Turks, and the *Porto Leone* of the Italians. The Greek and Italian names being derived from an immense line of Pentelic marble which stood originally upon the beach, nearly thirty-five or forty stadia distant from the city, and was displaced at the Venetian siege. The harbour had three docks, *Cantharos*, *Aphradisium*, and *Zea*; the first derived its name from an ancient hero, the second from the goddess *Venus*, the third from bread corn; it was dignified with several public buildings. A stoa, including five distinct stoæ or porticoes under the general name of *Macra Stoa*; two temples of *Venus*; a sanctuary of *Jupiter Soter*; the *Hippodameia*, from *Hippodamus* the architect, which was used as an agora or commercial exchange; two great fora or markets, one near the portico, the other near the city; the tribunal *Phreatys*; the bath *Seranium*; a deigma or maritime exchange, and a theatre, about 240 feet in diameter, some traces of which are yet remaining. The second of these harbours was *Mynychia*, to the east of *Piræus*, from which it is separated by a peninsula of the same name. It is of circular figure, and now called *Stratistiki*, and so strong is this promontory or peninsula by nature, that *Epimenes* said, if the Athenians saw what mischief it would one day produce to them, they would eat it away with their teeth. This part of Athens is adorned with a *Dionysæan* theatre, a temple of *Diana* of the *Doric* order, some remains of which are yet standing on the shore; also a *Bendideium*, probably in honor of the same goddess whose Thracian name was *Bendis*. The third and most ancient part was *Phalerum*, to the east of *Mynychia*, distant from the city, according to *Thucydides*, thirty-five stadia, and according to *Pausanias* twenty. It was formerly famous for the temple of *Jupiter*, *Ceres*, and *Minerva Sciras*, which have been long whelmed in ruin, and lost in the lapse of time.

WALLS, FORTIFICATIONS, &c.—*Piræus* from its natural division into three great basins, and also from its great capacity, became an object of capital importance with the Athenians; and accordingly it was fortified strongly in the second year of the *Poloponnesian* wars. The works which surrounded it consisted of a wall nearly seven miles in length and sixty feet in height. The long walls (*τὰ μακρὰ τεῖχη*, or *τὰ σκέλη*) extended from the city or city, on the north to *Pharos*, and on the south to *Phalerum*; a distance of five miles, protecting the city on every side from which any danger was apprehended.

These walls ran parallel to each other at the distance of 550 feet, from the centre of the *Phaleric* hill in the direction of the entrance of the *Acropolis*. The circumference of the whole walls, including those of the ports, the city, and the long walls, appears to have been about twenty miles. These walls were surrounded with cemeteries. The city was embraced by the streams of *Ilissus* and *Cephalus*, uniting in the marshes of *Phalerum*. The gates were, *Melitides*, *Peiraicæ*, *Acharnicæ*, *Ithoniæ*, *Hippades*, *Heriææ*, *Diomeiæ*, *Diocharis*, and *Dipylum*; called also, *Thrasia*, *Sacræ*, or *Cerameicæ*.

ENTRANCE FROM THE GATE PEIRAICÆ.—A cenotaph to *Euripides* adorned the outside of the gate *Peiraicæ*; within it stood the *Pompeion* for the arrangement of processions; and the interior of the city, from this view, seemed crowded with temples, statues, and porticoes. The *Nyx* (*δὴ το πεπικνωσθαι*), in which certain popular assemblies were held, stood on the right; the road continuing through the district of *Ceramicus*, passed the *Stoa Basileius*, or portico of the king, where the *Archon* held his court; at which point commenced the street of *Hermæ*, so called from *Mercury*, with whose head it was said to have been adorned; and after passing a considerable distance, ended in a stoa called *Pæcile*, from its numerous and highly finished pictures of the taking of *Troy*, the battle of *Marathon*, the battle of *Theseus* and the *Amazons*, and the battles with the *Lacedemonians* at *Enoe* and *Argolis*; to keep alive the remembrance of which the captured shields were also suspended.

AGORA.—The *Agora*, fronting the *Pæcile*, was planted with trees, and beautifully divided into markets, streets, porticoes, public halls, &c. One of these halls was for the assembling of the senate, another for the *Prytanes* to dine. Here stood a noble temple, also, to the mother of the gods, and altars to the twelve gods, to *Pity*, *Modesty*, *Fame*, and *Impetuosity*. The *Areopagus* sloped down from the north to a beautiful plane, where stood the temple of *Theseus*. It was called *Mars Hill*, because *Mars* was the first person tried here for murder, viz. for the murder of *Hallirhotius*. The *Theseium*, from its beautiful remains, must have been a most magnificent spot. It is a peripteral hexastyle, having on the sides thirteen columns of the *doric* order, each three feet four inches diameter at the base. The whole building is of *pentelic* marble, thirty feet in height, from the base to the summit of the pediment. The cell is forty feet in length, and twenty in breadth; the depth of the posticum is twenty-seven feet; that of the *pronaos* and portico thirty three. Contiguous to the *Theseium* were the *Gymnasium* of *Ptolemy*, the temple of the *Dioscuri*, and the *Horologium* of *Andronicus Cyrrhestes*. To the south-east stood the *Prytaneum* or *Senate house*, from which, the street of the tripods led to the theatre of *Bacchus*. This street was adorned by the victors in the prize games, and amongst its magnificent decorations stood the choragic monument of *Lysicrates* (the lantern of *Demosthenes*), the circular roof of which still preserves the triangular apex, intended to receive his native tripod. Adjoining to the theatre above mentioned stood the *Odeum*

of Pericles, from which, after passing through a gateway erected by Hadrian in the modern walls, arose the temple of Jupiter Olympius, which was completed and dedicated by the same emperor. It was of decastyle construction consisting of one hundred and twenty-four columns, sixteen of which are yet standing. Within it was a colossal statue of the god, made of ivory and gold (chryselephantine). The whole length of the sacred precinct (*περιβολος*) was 689 feet, and its circuit about half a mile.

THE HILL MUSEUM.—The fountain of Enneacrunos or Callirrhoe, the only natural spring by which Athens was supplied with palatable water, was on the Ilissus; from which, proceeding to the south-west angle of the walls we come to the hill Musæum, the summit of which is embellished by a monument of the Syrian C. J. Antiochus Philopappus, grandson of Antiochus IV. the last king of Comagene. He erected it on his return to Athens, after having been greatly honored by Trajan at Rome, and even made Consul and Frater Arvalis. The lower part was embellished with the grand triumph of his illustrious patron; above which were seated statues of himself, his grandfather Antiochus, and Seleucus Nicator, founder of the original dynasty. This monument has excited a degree of attention little inferior to that of Lysicrates above-mentioned.

ACROPOLIS.—On the north-east side of the Musæum, rises the Acropolis or ancient citadel. The rock is lofty, abrupt, and inaccessible, except the front, which is toward the Piræus; but furnishes a very ample field to the virtuosi. It was filled with monuments of Athenian glory, and exhibited an amazing display of beauty, of opulence, and of art. Heliodorus, named Periegetes the guide, has employed on it fifteen books. The curiosities of various kinds, with the pictures, statues, and pieces of sculpture, were so many and so remarkable as to supply Polemo Periegetes with matter for four volumes; and Strabo affirms, that as many would be required in treating of other portions of Athens and of Attica. In particular, the number of statues was prodigious. Tiberius Nero, who was fond of images, plundered the Acropolis as well as Delphi and Olympia; yet Athens, and each of these places, had not fewer than 3000 remaining in the time of Pliny. Even Pausanias seems here to be distressed by the multiplicity of his subject. But this banquet of the senses has long been withdrawn; and is now become like the tale of a vision. The spectator views with concern the marble ruins intermixed with mean flat-roofed cottages, and extant amid rubbish; the sad memorials of a nobler people; which, however, as visible from the sea, should have introduced modern Athens to more early notice. The Acropolis has only one entrance, which fronts the Piræus. The ascent is by traverses and rude fortifications furnished with cannon, but without carriages, and neglected. By the second gate is the station of the guard. Over this gate-way is an inscription in large characters on a stone turned upside down, recording a present of a pair of gates. Going farther up, you come to the ruins of the pro-

pylæa, an edifice which graced the entrance into the citadel. No fewer than four temples were to be passed in this ascent, those of Æsculapius, Themis, Venus and Peitho, also of Tellus and Ceres. Two equestrian statues stood in front of the wings of the propylæa, supposed to represent Marcus Agrippa, and Caius Cæsar Octavianus. The propylæa was one of the structures of Pericles, who began it when Euthymenes was archon, 435 years before Christ, and completed it in five years, at the expense of 2012 talents. It was of marble of the Doric order, and had five doors, to afford an easy passage to the multitudes which resorted on business or devotion to the Acropolis. Six fluted Doric columns raised on four steps, supported the central pediment, each five feet in diameter, twenty-nine in height, and seven in their intercolumniation, except between the two central columns, where was a space of thirteen feet, for the admission of carriages. Behind was a vestibule forty-three feet in depth, sustained by a double row of six Ionic columns, three and a half feet diameter, and thirty-four in height, three of which were placed on each side, whilst marble beams depending on the lateral walls and columns, supported a painted ceiling of exquisite workmanship. The doors contiguous to the frontage, opened into a portico of the depth of eighteen feet, upon a level of five steps ascent, from which a single step descended to the platform of the Acropolis. The middle door occupied the whole space between the central columns. The next door on each side was of inferior dimensions, and the two extreme doors proportionally smaller. The portico itself consisted of a large square room roofed with slabs of marble which were laid on two great marble beams, and sustained by four beautiful columns. These were Ionic, the proportions of that order best suiting the purpose as taller than the Doric. The roof which so exquisitely embellished the building, after standing above 2000 years, was with all the pediments destroyed in 1687 by the Venetian siege. The right wing of the propylæa is said to have been a temple of Victory. The Athenians related that Ægeus stood there, viewing the sea, anxious for the return of his son Theseus from Crete, and precipitated himself at the sight of the black sails. The idol was named Victory without wings, because the news of the success of Theseus did not arrive but with the conqueror. It had a pomegranate in the right hand, and an helmet in the left. As the statue was without pinions, it was hoped the goddess would remain for ever on the spot. On the left wing of the Propylæa, and fronting the temple of Victory, was a building decorated with paintings by Polygnotus, of which an account is given by Pausanias. This edifice, as well as the temple, was of the Doric order, the columns fluted, and without bases. Both contributed alike to the uniformity and grandeur of the design; and the whole fabric, when finished, was deemed equally magnificent and ornamental. Its roof of white marble, was unsurpassed both in the size of the stones, and in the beauty of their arrangement. On the northern side of the Acropolis within the propylæa, stood the celebrated statue of Mi-

nerva Promachus, executed by Phidias after the battle of Marathon. Its height together with the pedestal exceeded seventy feet, rising considerably above the summit of the parthenon; the crest of the helmet and point of the spear being seen out at sea, by persons sailing from Servium towards Athens; and a brazen quadriga stood near the statue in commemoration of the victory of the Athenians over the Bœtians and the Chalcidenses. See *HER.* v. 79.

The propylæa, according to the Greek historians, took five years in building, and was formed after the designs of Mnesicles. It was completed 437 years B.C. and was estimated by Heliodorus, as cited by Harpocration, at 2012 talents, or £452,700 sterling, and was the most expensive of all the works of Pericles.

PARTHENON.—But the chief glory of the Acropolis is said to have been the Parthenon, or temple of Minerva, so elevated that the pavement of its peristyle was on a level with the capitals of the eastern portico of the propylæa. It was a peripteral octostyle of the Doric order, with seventeen columns on the sides, each six feet two inches in diameter at the base, and thirty-four feet in height, elevated on three steps. Within the peristyle, at each end stood six columns of 5½ feet diameter, forming a vestibule to the cell which rose two steps from the peristyle level. The cell itself contained two chambers of sixty-two feet six inches in width, and of lengths differing from forty-three feet ten inches, to ninety-eight feet seven inches, the roof of the former being supported by four columns of four feet diameter, and of the latter by sixteen of three feet diameter. The height of the temple from the base to the pediment being fifty-six feet, and the dimensions of the area 228 feet, by 102. The pediment contained two compositions of about eighty feet in length, each containing upwards of twenty colossal statues, in two groups, the first representing the birth of the goddess Minerva, and the second her contest with Neptune, for the government of Attica. The figures of the western pediment enumerating them from the left were Cœrops, Aglaurus, Theseus, Hebe, Eresichthon, Pandrosus, Victory without wings drawn in a Biga by two horses, Erechtheus, Minerva and Jupiter in the centre, and to the right, Neptune, Thalassa, Latona, Mercury, Maia, Vesta, Mars and Venus. The figures which occupied the eastern pediment have never been perfectly ascertained. Some of them, however, were Hyperion, Hercules, Venus, Iris, Peitho, Vesta, Proserpine, Victory with wings, Ceres, and the car of Night. The frieze advancing in two parallel columns from west to east, was sculptured on both sides, and contained a representation of the Panathenæic procession. Six seated figures of deities also represented the head of each column, while the central group represented the presentation of the peplos to the second archon. Of the ninety-two metopes which anciently adorned the frieze of the peristyle, these on the south side, some of which are now in the British Museum, contained each a centaur, and hence those only of the eastern side have been assigned to the actions of Minerva: those of the western to some other point

of Athenian history, the subject of which has been lost; those of the northern to the Amazonian war; those of the southern to the war with the Centaurs. A chryselephantine statue of Minerva stood in the Opis, thodomos thirty-nine feet in height, the buskins sculptured with the battle of the Centaurs, and the Ægis which lay at her feet containing a representation of the battle of the Amazons on the outside, and on the inside that of the Titans. Ictinus is said to have been the architect of this temple; Phidias the artist; and the entire cost one million and a half sterling. The remains of this beautiful specimen of ancient architecture have been described by Dr. Chandler, a few extracts from whose observations we shall subjoin. 'The chief ornament,' he observes, 'of the Acropolis was the Parthenon or great temple of Minerva, a most superb and magnificent fabric. The Persians had burned the edifice, which before occupied the site, and was called hecatompedon, from its being 100 feet square. The zeal of Pericles and of all the Athenians was exerted in providing a far more ample and glorious residence for their favorite goddess. The architects were Calliocrates and Ictinus; it was of white marble, of the Doric order, the columns fluted and without bases, the number in front eight; and adorned with admirable sculpture. The story of the birth of Minerva was carved in the front pediment; and in the back, the contest with Neptune for the country. The statue of Minerva, made for this temple by Phidias, was of ivory, twenty-six cubits or thirty-nine feet high. It was decked with pure gold to the amount of forty-four talents, so disposed by the advice of Pericles as to be taken off and weighed, if required. This image was placed in the temple in the first year of the eighty-seventh Olympiad, in which the Peloponnesian war began. The gold was stripped off by the tyrant Lachares, when Demetrius Poliorcetes compelled him to fly. The same plunderer plucked down the golden shields in the Acropolis, and carried away the golden Victories, with the precious vessels and ornaments provided for the Panathenæan festival. The Parthenon remained entire for many ages after it was deprived of the goddess. The Christians converted it into a church, and the Mahomedans into a mosque. It is mentioned in the letters of Crusius, and mis-called the Pantheon, and the temple of the unknown God. The Venetians under Koningsmark, when they besieged the acropolis in 1687, threw a bomb, which demolished the roof, and setting fire to some powder, did much damage to the fabric. The floor, which is indented, still witnesses the place of its fall. This was the sad forerunner of farther destruction; the Turks breaking the stones, and applying them to the building of a new mosque, which stands within the ruin, or to the repairing of their houses and the walls of the fortress. The vast pile of ponderous materials, which lay ready, is greatly diminished; and the whole structure will gradually be consumed and disappear. The temple of Minerva in 1676 was, as Wheeler and Spon assert, the finest mosque in the world, without comparison. The Greeks had adapted the fabric to their ceremonial by constructing at one end a

semicircular recess for the holy tables, with a window: for before it was enlightened only by the door, obscurity being preferred under the heathen ritual, except on festivals, when it yielded to splendid illuminations; the reason, it has been surmised, why temples are commonly found simple and unadorned on the insides. In the wall beneath the window were inserted two pieces of the stone called phengites, a species of marble discovered in Cappadocia in the time of Nero; and so transparent that he erected with it a temple to Fortune, which was luminous within, when the door was shut. These pieces were perforated, and the light which entered was tinged with a reddish or yellowish hue. The picture of the Panagia or Virgin Mary, in Mosaic, on the ceiling of the recess, remained; with two jasper columns belonging to the screen, which had separated that part from the nave; and within, a canopy supported by four pillars of porphyry, with Corinthian capitals of white marble, under which the table had been placed; and behind it, beneath the window, a marble chair for the archbishop; and also a pulpit, standing on four small pillars in the middle aisle. The Turks had white-washed the walls, to obliterate the portraits of saints, and the other paintings with which the Greeks decorate their places of worship; and had erected a pulpit on the right hand for the iman or reader. The roof was disposed in square compartments; the stones massive; and some had fallen in. It had been sustained in the Pronaos by six columns; but the place of one was then supplied by a large pile of rude masonry, the Turks not having been able to fill up the gap more worthily. The roof of the naos was supported by colonnades ranging with the door, and on each side; consisting of twenty-two pillars below, and of twenty-three above. The odd one was over the entrance, which by that disposition was left wide and unembarrassed. In the portico were suspended a few lamps, to be used in the mosque at the seasons when the Mussulmans assemble before day-break, or to be lighted up round the minaret, as is the custom during the Ramazan or Lent. It is not easy to conceive a more striking object than the Parthenon, though now a mere ruin. The columns within the naos have all been removed: but on the floor may be seen the circles which directed the workmen in placing them; and at the farther end is a groove across it, as for one of the partitions of the cell. The recess erected by the Christians is demolished; and from the rubbish of the ceiling, the Turkish boys collect bits of the Mosaic, of different colors, which composed the picture. We are told at Smyrna, that this substance had taken a polish, and been set in buckles. This cell is about half demolished; and in the columns which surround it, is a large gap near the middle. On the walls are some traces of the paintings. Before the portico is a reservoir sunk in the rock, to supply the Turks with water for the purifications customary on entering their mosques. In it, on the left hand, is the rubbish of the pile erected to supply the place of a column; and on the right a staircase which leads out on the architrave, and has a marble or two with inscriptions, but worn

so as not to be legible. It belonged to the minaret, which has been destroyed. The travellers, to whom we are indebted for an account of the mosque, have likewise given a description of the sculpture then remaining in the front. In the middle of the pediment was seen a bearded Jupiter, with a majestic countenance, standing, and naked; the right arm broken. The thunderbolt, it has been supposed, was placed in that hand, and the eagle between his feet. On his right was a figure, it is conjectured, of Victory, clothed to the mid-leg; the head and arms gone. This was leading on the horses of a car, in which Minerva sat, young and unarmed; her head-dress, instead of a helmet, resembling that of a Venus. The generous ardor and lively spirit visible in this pair of celestial steeds, was such as bespoke the hand of a master, bold and delicate, of a Phidias or Praxiteles. Behind Minerva was a female figure, without a head, sitting, with an infant in her lap; and in this angle of the pediment was the emperor Hadrian with his arm round Sabina, both reclining, and seeming to regard Minerva with pleasure. On the left side of Jupiter were five or six other trunks to complete the assembly of deities into which he received her. These figures were all wonderfully carved, and appeared as big as life. Hadrian and his consort, it is likely, were complimented by the Athenians with places among the marble gods in the pediment, as benefactors. Both of them may be considered as intruders on the original company; and possibly their heads were placed on trunks, which before had other owners. They still possess their corner, and are easy to be recognised, though not unimpaired. The rest of the statues are defaced, removed, or fallen. Morosini was ambitious to enrich Venice with the spoils of Athens; and by an attempt to take down the principal group, hastened their ruin. In the other pediment is a head or two of sea-horses finely executed, with some mutilated figures; and on the architrave beneath them are marks of the fixtures of votive offerings, perhaps of the golden shields, or of festoons suspended on solemn occasions, when the temple was dressed out to receive the votaries of the goddess.

ERECHEIUM.—The erechtheum, about 160 feet north of the parthenon, containing the united temples of Minerva, Polias Pandrosus, or, according to some writers, Neptune, was of irregular figure, the eastern front of which presented a hexastyle Ionic colonnade, the western being pseudo-peripteral, and the entablature supported by half columns. Two deities are supposed to have inhabited two great divisions in the interior. The Pandrosseium (according to some) on the western side, opened into porticoes to the north and south; the former being tetrastyle, and the latter supported by six caryatides. This beautiful edifice was small, the entire area not exceeding sixty-three feet by thirty-six, nor the height twenty. Here was preserved the mark of Neptune's trident, which struck when the horse issued forth; also the olive-tree of Minerva; an image of the goddess which fell from heaven, before which was suspended a golden lamp, the wick of which, being Carpathian flax, never consumed, and required oil but once a

year; together with a brazen palm-tree above it, which carried off the smoke; the wooden Hermes presented by Cecrops; the chair by Dædalus; the scimitar of Mardonius; the breastplate of Masistrus, who commanded the Median cavalry at Plataea; and numerous groups of statues.

As Dr. Chandler's description of this celebrated depository of arts, at the time of his visit, is highly interesting, we shall again refer the reader to that authority. 'Neptune and Minerva,' observes the Dr. 'once rival deities, were joint and amicable tenants of the Erechtheum, in which was an altar of Oblivion. The building was double, a partition wall dividing it into two temples, which fronted different ways. One was the temple of Neptune Erechtheus, the other of Minerva Polias. The latter was entered by a square portico connected with the marble skreen, which fronts towards the propylæa. The door of the cell was on the left hand; and at the further end of the passage was a door, leading down into the Pandroseum, which was contiguous. Before the temple of Neptune Erechtheus, was an altar of Jupiter the supreme, on which no living thing was sacrificed, but they offered cakes without wine. Within it was the altar of Neptune Erechtheus; and two, belonging to Vulcan, and a hero named Butes, who had transmitted the priesthood to his posterity, which were called Butadæ. On the walls were paintings of this illustrious family, from which the priestess of Minerva Polias was also taken. It was asserted, that Neptune had ordained the well of salt water, and the figure of a trident in the rock, to be memorials of his contending for the country. The former, Pausanias remarks, was no great wonder, for other wells of a similar nature, were found inland; but this, when the south wind blew, afforded the sound of waves. The temple of Minerva Polias was dedicated by all Attica, and possessed the most ancient statue of the goddess. This temple was burned when Callias was Archon, twenty-four years after the death of Pericles. Near it was the tomb of Cecrops, and within it Erechtheus was buried. The ruin of the Erechtheum is of white marble; the architectural ornaments of very exquisite workmanship, and uncommonly curious. The columns of the front of the temple of Neptune are standing with the architrave; and also the skreen and portico of Minerva Polias, with a portion of the cell, retaining traces of the partition wall. The order is Ionic. An edifice revered by ancient Attica, as holy in the highest degree, was, in 1676, the dwelling of a Turkish family, and is now deserted and neglected; but many ponderous stones and rubbish must be removed before the well and trident would appear. The former, at least, might probably be discovered. The portico is used as a powder magazine; but we obtained permission to dig and to examine the outside. The doorway of the vestibule is walled up, and the soil risen nearly to the top of the door-way of the Pandroseum. By the portico is a battery commanding the town, from which ascends an amusing hum. The Turks fire from it, to give notice of the commencement of Ramadan, or of their Lent, and of Bairam, or the holy days.'

SCHOOLS, GYMNASIA, &c.—The schools and

places of public instruction of Athens during her prosperity were several; the most celebrated were two called Ceramicus; one within the city, containing a multitude of buildings of all sorts; the other in the suburbs, in which was the academy and other edifices. There were many gymnasia in Athens; the most remarkable were the Lyceum, Academia, and Cynosarges. The Lyceum stood on the banks of Ilissus; some say it was built by Pisistratus, others by Pericles, others by Lycurgus. Here Aristotle taught philosophy, instructing such as came to hear him as they walked, whence his disciples derived the name of Peripatetics. It was also the place where the Polemarch kept his court, and the chief gymnasium of the Athenian youth. The ceramicus without the city was six stadia from its walls. The academy made part thereof. It was a marshy unwholesome place till Cimor got it drained, and then it became extremely pleasant and delightful, being adorned with shady walks, where Plato read his lectures, and from thence his scholars were styled Academics. The Cynosarges, sacred to Hercules, and commonly considered as the position occupied by the Athenians after the battle of Marathon, when the Persians sailed to Phalerum, was a place in the suburbs not far from the Lyceum; it was famous on many accounts, but particularly for a noble gymnasium erected there, appointed for the special use of such as were Athenians only by one side. Themistocles got much ill-will by carrying many of the nobility to exercise with him here, because, being but of the half-blood he could exercise nowhere else but in this gymnasium. Antisthenes instituted a sect of philosophers, who from the name of this district, as many think, were styled Cynics.

Of the walls of the acropolis the southern is called the Cimonian and the northern the Pelasgic; both commonly attributed to Cimon and Themistocles. A few rude fragments of the ancient Hecatompedum are still remaining in the latter, of Doric architecture, supposed to be the workmanship of the original Pelasgi, who first fortified the citadel anterior to the invasion of the Persians. On the northern side of the Propylæa is still to be seen an ancient grotto, consecrated to Apollo and Pan, in which the former received the favors of Creusa, daughter of Erechtheus. It was descended by a flight of steps.

The other remarkable places and erections are the Stadium, south of the Lyceum, constructed by Lycurgus for the contest of the panathenæic festival, 350 B. C., and afterwards covered with marble by Herodes Atticus. It measured 675 feet by 130, and was capable of accommodating upwards of 25,000 persons. The temple of the Eumenides stood upon the hill Colonos, sacred to Neptune, and celebrated in the history of Ædipus. It was about a mile and a quarter north of the walls, and between it and the city lay the sepulchral plain. To the east rises a hill, supposed to be the mount Anchesmus of the ancients, and at present one of the most remarkable features of modern Athens, occupied by the church of St. George.

REMAINS OF THE TEMPLE OF JUPITER OLYMPIUS.—The ruins of the temple of Jupiter Olym-

pius and several other remarkable antiquities are thus described by the celebrated gentleman to whom we have already referred. 'The ruin of the temple of Jupiter Olympius,' says he, 'consists of prodigious columns, tall and beautiful, of the Corinthian order, fluted; some single, some supporting their architraves; with a few massive marbles beneath; the remnant of a vast heap, which only many ages could have consumed and reduced into so scanty a compass. The columns are of very extraordinary dimensions, being about six feet in diameter, and nearly sixty in height. The number, without the cell, was 116 or 120. Seventeen were standing in 1676; but, a few years before we arrived, one was overturned with much difficulty, and applied to the building a new mosque in the bazar or market-place. This violence was avenged by the bashaw of Negropont, who made it a pretext for extorting from the vaiwode, or governor, fifteen purses; the pillar being, he alleged, the property of their master, the grand seignior. It was an angular column and of consequence in determining the dimensions of the fabric. We regretted that the fall of this mighty mass had not been postponed until we came, as it would have afforded an opportunity of inspecting and measuring some members which we found far too lofty to be attempted. On a piece of the architrave, supported by a couple of columns, are two parallel walls of modern masonry, arched about the middle, and again near the top. You are told it has been the habitation of a hermit, doubtless of a Stylites; but of whatever building it has been part, and for whatever purpose designed, it must have been erected thus high in air while the immense ruin of this huge structure was yet scarcely diminished, and the heap inclined so as to render it accessible. It was remarked that two stones in a step in the front had coalesced at the extremity, so that no juncture could be perceived; and the like was discovered also in a step of the Parthenon. In both instances it may be attributed to a concretionary fluid, which pervades the marble in the quarry. Some portion remaining in the pieces when taken green, as it were, and placed in mutual contact, it exuded and united them by a process similar to that in a bone of an animal when broken and properly set. Besides the more stable antiquities, many detached pieces are found in the town, by the fountains, in the streets, the walls, the houses, and churches. Among these are fragments of sculpture, a marble chair or two, which probably belonged to the gymnasia or theatres; a sun-dial at the catholicon, or cathedral, inscribed with the name of the maker; and, at the archiepiscopal house close by, a very curious vessel of marble, used as a cistern to receive water, but once serving, it is likely, as a public standard or measure. Many columns occur with some maimed statues and pedestals, several with inscriptions, and almost buried in earth. A custom has prevailed, as at Chios, of fixing in the wall, over the gateways and doors of the houses, carved stones, most of which exhibit the funeral supper. In the courts of the houses lie many round stelæ or pillars, once placed on the graves of the Athenians; and a

great number are still to be seen applied to the same use in the Turkish burying-grounds before the acropolis. These generally have concise inscriptions containing the name of the person, and of the town and tribe to which the deceased belonged. Another species, which resembles our modern head-stones, is sometimes adorned with sculpture, and has an epitaph in verse. We saw a few mutilated hermæ. These were busts on long quadrangular bases, the heads frequently of brass invented by the Athenians. At first they were made to represent only Hermes or Mercury, and designed as guardians of the sepulchres in which they were lodged, but afterwards the houses, streets, and porticoes of Athens, were adorned with them, and rendered venerable by a multitude of portraits of illustrious men and women, of heroes, and of gods; and it is related that Hipparchus, son of Pisistratus, erected them in demi or borough towns, and by the road side, inscribed with moral apophthegms in elegiac verse; thus making them vehicles of instruction.'

DECLINE OF ATHENS.—The decline of Athens, one of the most remarkable subjects of history, was occasioned by that great revolution which took place in the moral world upon the propagation of Christianity and the consequent annihilation of those idolatrous superstitions which had been handed down from the ages bordering on the deluge. The general conduct of the early Christians, wherever their influence extended, was to destroy all works of pagan architecture dedicated to the purposes of superstition, whilst, by propagating the gospel and thoroughly extinguishing the principles that gave birth to them, no hope remained of their reproduction. At Athens, however, the early Byzantine emperors forbore to destroy these sacred edifices, and in lieu of it consecrated them to the Christian cause. Even Alaric used every effort for the preservation of Athens, and the noble statue of Minerva Promachus still crowned the city and towered above the uninjured Parthenon at the close of the fourth century. During the ducal government of the Franks, however, the city dwindled to the rank of a provincial town, and in 1436 Omar took possession of it in the name of Mahomet. This was shortly followed by the ruin of the city and the demolition of those stupendous works of art which had been the wonder of so many ages.

VENETIAN INVASION.—In 1687 the Venetians, as already intimated, under count Koningsmark, a Swede, besieged the acropolis. The explosion of the beautiful temple of Victory without wings, (*μνη αμπερος*) the frieze of which is now in the British Museum, followed the bombardment; an explosion of the Parthenon followed; the eastern wall and statues of that pediment were thrown to the ground; the middle of the temple was destroyed; the western front considerably shaken, and little less except part of the opisthodomos and a few of the lateral columns of the peristyle adjoining the cell were left standing. These two celebrated temples, which had been used by the Turks as powder-magazines, constituted the chief glory of Athens, and after the destruction of these she surrendered. During

the short time the Venetians held possession of the city several ancient monuments were destroyed. A celebrated car of Victory, which stood on the western pediment of the Parthenon, with horses of a natural size, was taken down by the Doge Morosini, with a view of being removed to Venice, but in lowering it to the ground the engineers suffered it to fall, by which it was entirely destroyed.

KNOWLEDGE OF ATHENIAN ANTIQUITIES IN EUROPE.—The antiquities and works of Athens were little noticed in Europe till the close of the 17th century. The accounts received by means of travellers had been mostly perplexed and mistaken. Some called the Parthenon the pantheon, and described it to be oval, others thought it the temple of the unknown God, mentioned in the narrative of the apostle Paul. Sir G. Wheeler, and Dr. Spon, who visited Athens before the Venetian siege, were the first who by their description of the city impressed European nations with the great value of these celebrated remains. The Dilletanti society employed Dr. Chandler, already quoted, to visit this famous depository of the sciences, and examine its antiquities and topography. Mr. Stuart, an ingenious artist, also went over from England, and employed three years in studying and forming correct drawings of its principal remains.

LAUDABLE EFFORTS OF LORD ELGIN.—Lord Elgin, on his appointment as ambassador to the Porte in 1799, established a society of distinguished artists in Athens, who in three years presented him with a complete body of finished drawings of the plans and details of the most important monuments and remains, accompanied by just admeasurements of the elevation and extent, besides bas-reliefs and characteristic features of Athenian architecture, moulded from the originals, in which they were the more diligent, as the Turks from motives of avarice were in the habit of breaking up marbles, in the hope of finding some hidden treasure under them, and of defacing the most perfect sculptures from motives of superstition. The British ambassador, who appears to have been a man of taste and genius, employed his interest at the Porte in obtaining permission to remove some of the most valuable marbles, and transfer them to England, the French having removed some valuable deposits to the gallery of the Louvre.

LORD ELGIN'S COLLECTION OF ANTIQUITIES, &c.—Lord Elgin's collection consisted chiefly of the following articles: Several original Metopes from the interior frieze of the Parthenon, descriptive of the combat between the Centaurs and the Lapithæ; part of the outer frieze of the same temple, representing the procession at the Panathenæic festival, both of which occupied the pediments of the eastern and western fronts, the former being in such high relief as to seem groups of statues. Several inscriptions after the Kionedon manner, in which singular care is taken to preserve an equal number of letters in each line, occasionally even to the division of monosyllables. A Doric capital, assizes of the columns, a triglyph, some of the modules of the cornice, and a few of the marble tiles (antefixa,) which roofed the original ambulatory. Models

of the metopes in the temple of Theseus, containing the labors of Theseus and Hercules, taken from the interior frieze, representing the battle of the Centaurs and Lapithæ; together with several incidents of the battle of Marathon. The temple being in a considerable state of preservation, the originals could not be obtained. In addition to these he obtained from the vestibule of the temple of Neptune, and that of Minerva Polias, in the Erechtheum, a capital, a base, and some original blocks of the frieze and cornice, with plans of the architecture, &c. From the adjoining Pandroseium, one of the Caryatides. From the temple of the bearded Bacchus, a statue of the god, and a sun-dial, said to have existed in the time of the tragedians. The convents and other buildings furnished bronzes, cameos, intaglios, and medals. Besides the above laudable undertakings, he traced the walls of the city, made extensive excavations, and, from the numerous tumuli which opened in the suburbs, formed a magnificent collection of the vases hitherto improperly denominated Etruscan. But perhaps one of his most successful efforts was the removing of the celebrated Boustrophedon inscription, which anciently adorned the Sigeon promontory. This celebrated monument had for some time formed a seat at the door of a Greek chapel, and was the resort of persons afflicted with the ague; the letters having been nearly obliterated by the numbers of patients who had reclined upon it. The most valuable part of his collection has been thought by some to be a complete series of Doric, Ionic, and Corinthian capitals, from the birth of Athenian architecture to its greatest height under Pericles. The same gentleman obtained some fragments of the temple of Victory without wings, on the right of the propylæa, representing scenes from the battles of Marathon, Salamis, and Plataea, which had been built in the wall of a powder magazine; the finest blocks of the whole being placed in an inverted position. These and some other sculptures were afterwards embarked for England, but unhappily wrecked off the island of Cerigo. Many cases however by the assistance of the most expert divers were obtained from the vessel, at the depth of twenty fathoms of water, and the remainder, although two successive winters of laborious exertion were employed about them, were left upon the wreck. On the acquisition of so numerous a collection of remains from the most valuable part of Athenian antiquity, the British ambassador conceived the idea of engaging the most distinguished of the modern artists, to attempt their restoration, but they declined the task. Canova, in particular, affirmed that the marbles of the ancient parthenon had never been retouched, and were so superior in their style of execution, that it would be sacrilege for any man to presume to violate them with a chisel. They were therefore transported to England as Athenian originals, and purchased by a £35,000 grant of Parliament, to enrich the British Museum, where they still remain to guide the improvements of taste, and excite the emulation of modern genius.

PRESENT STATE OF ATHENS.—The present state of Athens, like that of most other celebra-

ted cities of antiquity, exhibits a remarkable spectacle of fallen greatness. The Acropolis was converted into a Turkish fortress, and placed under the government of a waywode, or lieutenant, who is chief black eunuch of the seraglio. The town is surrounded by an insignificant wall, about ten feet in height, far short of the dimension of its ancient circumference. The streets are narrow. The population is diminished to one-tenth of its number in the time of Demosthenes, said to have been 116,000. The Acropolis is disfigured by a huge Venetian tower,

erected when under the dominion of that republic, the architecture of which looks the more barbarous, from the highly finished models that surround it. The parthenon is degraded in the front by a mean house, in which resides the disdar, or governor of the fortress, and the south-east angle exhibits a wretched mosque. The town is chiefly inhabited, by Turks and Christians of the Greek church. It is the see of an archbishop, under whom five archons and a number of secretaries are appointed to the management of its ecclesiastical concerns.

ATHENS, a flourishing post town of New York, on the west bank of the Hudson, opposite Hudson city. The situation of this place is pleasant, and very eligible for trade. It contains a Lutheran church, three school-houses, and a market-house, an extensive rope-walk, a large distillery, a pottery of stoneware, and other smaller manufactories. Population 1000. Twenty-eight miles south of Albany.

ATHERINA, in ichthyology, a genus of fishes of the order of abdominales. The characters of this genus are these:—the upper jaw plain; the rays of the branchiostege membrane are six; and the side belt or line shines like silver. The species are two, viz.

1. *A. hepsetus*, the smelt, with about twelve rays in the fin next the anus. It is found in the Mediterranean, and is also very common in the sea near Southampton. The highest season is from March to the beginning of June; in which month it spawns. It is also found on other coasts of our island.

2. *A. midea*, has twenty-four rays in the fin next the anus. This is a very pellucid fish, with many black points interspersed; it has many teeth in the lips, but none in the tongue or jaws. It is found in the fresh waters of Carolina, and spawns in April.

ATHERINOIDES, a species of clupea, distinguished by a silvery lateral line. In the dorsal fin are twelve rays; fourteen in the pectoral fins; eight in the ventral fins; thirty-two in the anal fin; and eighteen in the tail. It is a native of Surinam.

ATHERIX, in entomology, a genus of the order diptera, and family rhagionide. Its generic characters are antennæ moniliform; the third joint not ringed, but terminated by a seta, the palpi erect. The only known species is maculatus, found in the woods of Great Britain.

ATHEROMA, a kind of tumor, occurring chiefly in the neck and arm-holes, and containing matter resembling *αθηρα*, or pap, intermixed with hard and stony particles. These tumors are easily cured by incision.

ATHESIS, in ancient geography, a river of Cisalpine Gaul, which, rising in the Rhetian Alps, runs southward, and washes Tridentum and Verona, which last it divides; and afterwards bends its course eastward, and falls into the Adriatic, between Fossa Claudia and Philistina. It separated the country of the Euganei from that of the Veneti. It is now called the Adige.

ATHIAS (Joseph), a learned Jewish printer in the seventeenth century. He resided at Amsterdam, where, in 1667, he published a Hebrew bible, which is held in great estimation. He likewise printed the bible in Spanish, German, and English. The States presented him with a gold medal and chain, as a mark of the value they put upon his labors.

ATHIRST. On thirst. See THIRST.

With scanty measure then supply their food;
And, when *athirst*, restrain 'em from the flood.

Dryden.

Unnumbered supplants crowd Preferment's gate,
Athirst for wealth, and burning to be great;
Delusive Fortune hears the incessant call,
They mount, they shine, evaporate, and fall.

Johnson.

ATHLETÆ, *Ἀθλητῆς*, Gr. from *αθλος*, a combat; in antiquity, persons of strength and agility, disciplined to perform in the public games. Under *Athletæ* were comprehended wrestlers, boxers, runners, leapers, throwers of the disk, and those practised in other exercises, exhibited in the Olympic and Pythian games, &c. for the conquerors in which there were established prizes. To obtain a firm, bulky, weighty body, by force of which they frequently overpowered their antagonist, they fed altogether on dry, solid, and viscous meats. In the earlier times their chief food was dry figs and cheese, which was called *arida saginatio*, *ξέρα τροφή*. Orbasius first brought this in disuse, and substituted flesh instead of these. They had a peculiar bread, called *κολητια*: they exercised, eat, and drank, without ceasing; were not allowed to leave off eating when satiated, but were obliged to cram on till they could hold no more; by which means they at length acquired a degree of voracity, which to us seems incredible, and a strength proportional. Pausanias relates of Milo, the Crotonian, that he carried a bull on his back a considerable way, then knocked him down with a blow of his fist, and, lastly, devoured him at a meal!

ATHLETE, } *Ἀθλητής*, a wrestler in the
ATHLETICK. } agonistic exercises of the
Greeks; from *αθλος*, labor. One whose physical powers enable him to labor, struggle, contend.

And health itself, if it be *athletic*, may by its very excess become dangerous.

Bp. J. Taylor.

Science distinguishes a man of honour, from one of those *athletic* brutes, whom undeservedly we call heroes.

Dryden.

Was he [the wise man] in adversity; he equally returned thanks to the director of this spectacle of

human life, for having opposed to him a vigorous *athlete*, over whom, though the contest was likely to be more violent, the victory was more glorious and equally certain. *Smith's Moral Sentiments.*

ATHLON, Gr. *Ἀθλον*, in antiquity, the prize adjudged to the victor, in the athletic exercises, at the public games.

ATHLONE, a town of Ireland, pleasantly situated on both sides of the Shannon; the one half lying in the county of Westmeath, and the other in that of Roscommon. These divisions of the town are united by a well built bridge, in the middle of which stands a monument, on which there are some badly executed figures and inscriptions, celebrating the success of Queen Elizabeth of England, and relating how the rebels in her reign were executed, quartered, and their skulls, &c. stuck upon poles, about the country, and at Dublin castle; and every thing brought into a state of the greatest prosperity. Athlone, though so advantageously situated for trade, still remains a poor, ruinous, neglected, dirty place. The castle was founded by king John, on some land belonging to St. Peter's abbey, for which he granted a compensation. It is built on a high raised round hill, resembling one of the Danish forts. It had formerly two convents, and was strongly fortified. In 1691 part of the English army under General Ginckle, although the Irish were strongly entrenched on the opposite shore, forded the river, stormed and took possession of the town, not losing more than fifty men in the attack; which is esteemed as bold an enterprise as any recorded in history. General Ginckle obtained the title of Earl of Athlone, as a reward for his services. There are generally two troops of horse, and four companies of foot, quartered at Athlone. Athlone is fifty-nine miles west from Dublin. This place returns one member to parliament.

ATHLOTHETA, in antiquity, an officer appointed to superintend the public games, and adjudge the prizes. The *athlotheta* was otherwise called *asymmetta*, *brabuta*, &c.

ATHNACH, the name of one of the principal of the Hebrew accents, which serves not only to regulate the voice, but to distinguish the members of a sentence, whence its name *athnach*, i. e. respiration. On this account it is called king and pause, and answers to our colon, and sometimes to a note of interrogation. It is marked under a letter thus *κ*.

ATHOL, or *ATHOLL*, the most northern district of Perthshire in Scotland, extending in length forty-three miles, and in breadth thirty. The country is very rough and mountainous, and contains part of the ancient Caledonian forest: but these mountains are interspersed with fruitful valleys. It has several villages, but no town of any consideration. The most noted place is Blair castle, which belongs to the duke of Atholl, who derives his title from this district. In the neighbourhood is the pass of Killieranky, rendered memorable by the battle fought there, in the beginning of king William's reign, between general McKay, and the Highlanders adhering to king James.

ATHIOS, a mountain of Chalcidica in Macedonia, celebrated in ancient and modern times.

The ancients entertained extravagant notions concerning its height; and it was a received opinion, that the summit of mount Athos was above the middle region of the air, and that it never rained upon it. Its modern name of Monte Santo (Holy Mount) it has got from the number of Greek monasteries that are built on it. They amount to nearly thirty, are protected by fortifications from the incursions of the corsairs, and are inhabited by about 6000 monks, who lead a life of monotony and indolence. The air is remarkably pure, and many of the inhabitants reach a great age. About half-way up the hill lies a small town, called Kareis, which is also fortified, and is the seat of the Turkish aga. A market is held here every Saturday, from which females are excluded. They pay an annual tribute for protection to the Turkish government. The manuscripts in their libraries have been recently examined, and some account of them will be found in Dr. Clarke's Travels. According to the accounts of modern travellers, this mountain advances into the Archipelago, on the south of the Gulf of Contessa, and is joined to the continent by an isthmus about half a league in breadth. It is about thirty miles in circumference, and two in perpendicular height. It abounds with many different kinds of plants and trees, particularly the pine and fir. In the valleys grows a plant called *elegia*, whose branches serve to make pens for writing. Through this mountain, or rather through the isthmus behind it, Xerxes, king of Persia, is said to have cut a passage for his fleet when about to invade Greece. In this work he spent three whole years, and employed in it all the forces on board the fleet. He is also said, before the work was begun, to have written the following ridiculous letter to the mountain: 'Athos, thou proud and aspiring mountain, that liftest up thy head to the very skies, I advise thee not to be so audacious, as to put rocks and stones, that cannot be cut, in the way of my workmen! If thou makest that opposition, I will cut thee entirely down, and throw thee headlong into the sea!' The directors of this enterprise are said to have been Bubaris, the son of Megabyzus, and Artacheus, the son of Arbeus, both Persians; but, as no traces of such a great work remain, the truth of the whole relation has been questioned. Dinocrates, a sculptor, who followed the march of Alexander, offered to convert mount Athos into a statue of that king, holding a town in his right hand, and in his left a basin large enough to contain all the waters that flowed from it; but the proposal was deemed too extravagant to be accepted. This venerable mountain constitutes one entire chain, extending seven miles in length, and three in breadth, and is situated about seventy miles east of Salonichi, the ancient Thessalonica.

ATHULIA, in entomology, a very small species of *papilio*, found in the northern parts of Russia. This is the *papilio phæbe* of Esper, and belongs to the family *satyri* in the Fabrician system.

ATHWART, *prep. & adj.* From to thwart. Across; in a transverse direction; figuratively, wrong, in a vexatious manner.

There let the classic page thy fancy lead
Through rural scenes, such as the Mantuan swain
Paints in the matchless harmony of song ;
Or catch thyself the landscape gliding swift
Athwart Imagination's vivid eye. *Thomson.*

Shook sudden from the bosom of the sky,
A thousand shapes, or glide *athwart* the dusk,
Or stalk majestic on. *Id.*

With thee, my bark, I'll swiftly go,
Athwart the foaming brine ;
Nor care what land thou bear'st me to,
So not again to mine.

Lord Byron's Child Harold.

ATHWART, in navigation, is synonymous with across the line of the course. It is also used in other senses, such as,

ATHWART-HAUSE, expresses the situation of a ship, when she is driven by wind or tide, or any other accident across the fore part of another

ATHWART-SHIPS, reaching across ships from one side to the other.

ATHWART THE FORE FOOT, denotes the flight of a cannon ball from one ship across the course of another, to intercept the latter, and oblige her to shorten sail, that the former may come near enough to examine her.

ATHY, a town of Ireland, in the county of Kildare, near the borders of Queen's county. It is situated on the river Barrow, on which boats pass by Carlow to Waterford. It is ten miles south of Kildare, and thirty-two south-west of Dublin; from which a branch of the grand canal extends, and boats pass between them daily, through the whole extent. It is governed by a sovereign, two bailiffs, and a recorder; and is, alternately with Naas, the assizes town.

ATHYMIA, *αθυμία*, despondency; dejection of the spirits.

ATIBAR, the name by which the inhabitants of Gago in Africa call gold-dust; from which word Europeans, and especially the French, have composed the word *tiber*, which also signifies gold-dust among those who trade in that commodity.

ATILIA, in ancient records, signifies utensils, implements for country business.

ATILT. On tilt. Lifted up in the attitude of attack; also, any thing with one end lifted up, as a barrel.

In the city Tours

Thou ran'st *atilt*, in honour of my love ;
And stol'st away the ladies' hearts from France. *Shakspeare.*

To run *atilt* at men, and wield
Their naked tools in open field. *Hudibras.*

Such a man is always *atilt*; his favours come
hardly from him. *Spectator.*

ATINGA GUACU-MUCU. See **CORNUTUS CUCULUS**.

ATINGA, in ichthyology, a species of diodon, of an oblong form, beset with rounded spines. It is called by Maregrave, *guamajucu antinga*; and in England is known by the name of porcupine fish.

This species lives in the American seas, and about the Cape of Good Hope. Its food consists of crabs and other shell-fish. The length rather exceeds twelve inches; the body is compressed at the sides, and bluish. This creature has the

power of dilating its body, and erecting its spines at pleasure. It is usually taken in nets, but will also take bait, which is commonly the tail of a crab, fastened on the hook.

ATINIA LEX, a law passed by the tribune Atinius, which gave a tribune of the people the privileges of a senator, and the right of sitting in the senate.

ATIZOE, in the writings of ancient naturalists, a stone used in the consecration and anointing of kings. Pliny describes it to have been of a lenticular figure, and of the size of three fingers, of a bright silvery color, and of a pleasant smell. He says it was found in India, and in some other places. Agricola is of opinion it was a kind of bitumen.

ATKINS (James), bishop of Galloway, the son of Henry Atkins, sheriff of Orkney, was born at Kirkwall, educated at the university of Edinburgh, where he took the degree of A. M. and finished his studies at Oxford, under the celebrated Dr. Prideaux, about A. D. 1638. Being appointed chaplain to the Marquis of Hamilton, he was soon after presented to the church of Birsay in Orkney, where he was much esteemed. In 1650, being moderator of the presbytery, he was appointed to draw up a declaration of loyalty, in their names, and present it to the Marquis of Montrose; for which he and the whole presbytery were deposed by the general assembly, and the doctor was excommunicated for corresponding with the Marquis. The council soon after passed an act for bringing him to trial, but being privately warned by his friend, Sir Archibald Primrose, the clerk of council, he fled to Holland, where he remained till 1653, when he returned to Edinburgh, and resided in quiet obscurity till the restoration. He then accompanied Dr. Sydeserf to London, and obtained the rectory of Winfrith. In 1677 he was elected bishop of Moray, and in 1680 translated to the see of Galloway, which he governed seven years, and died much respected in 1687, aged seventy-four.

ATKINS (Sir Robert), lord chief baron of the exchequer, was born in 1621, and educated at the university of Oxford, from whence he removed to the inns of court, and became eminent in the law. He was made knight of the bath, at the coronation of king Charles II. In 1662 he was appointed one of the judges of Common Pleas; in which station he continued till 1679, when foreseeing the troubles that soon after ensued, he resigned, and retired into the country. In 1689 he was made by king William lord chief baron of the exchequer; and about the same time filled the office of speaker to the house of lords. He distinguished himself by an unshaken zeal for the laws and liberties of his country; and wrote several pieces which have been collected into one volume 8vo. under the title of *Parliamentary and Political Tracts*.

ATLANTEAN. Possessing the strength of Atlas.

Where are the pillars, that support the skies?
What more than *Atlantean* shoulder props
Th' incumbent load? What magic, what strange art,
In fluid air these pond'rous orbs sustain?

Young's Night Thoughts, iv

ATLANTES. See ATLAS.

ATLANTIC. The Atlantic Ocean is that great basin of waters that separates Europe and Africa on the east, from America on the west, and stretches from the arctic ocean on the north to a line which joins Cape Horn and the Cape of Good Hope on the south. It is divided from the north sea, on the north-east, by the Straits of Dover, Great Britain, the isles of Faroe and Iceland. The Mediterranean with its gulfs, the Gulf of Mexico, and Hudson's and Baffin's Bay, are consequently branches of it. That part of the Atlantic, however, between Brasil and Africa, and from the nearest approximation of these countries to the southern limits, is sometimes called the Ethiopic Ocean. It has been conjectured that the vast bed of the Atlantic was formed at the time of the deluge, by the great southern ocean below the equator, rushing on the northern hemisphere. This the shape of the opposite shores has been supposed to justify, which have the exact appearance of having been formed by the action of water, the great protuberances of the one corresponding to the indentations of the other. One of the most remarkable features of the Atlantic is its currents. It partakes of the general current which flows from the poles towards the equator, and which arises from the increased evaporation in the equatorial regions, and the augmented temperature of the waters, rendering them specifically lighter than those of the ocean in higher latitudes, as well as from the increased supplies produced by the melting of the polar ice. The existence and effects of this great current are fully proved by the enormous masses of polar ice, which they convey into the more temperate regions of the ocean, and which sometimes float as low as 40° of latitude.

The coast of America, and the numerous islands with which it is flanked, intercept the general current of the Atlantic, and create what navigators call the gulf stream. This enters the Gulf of Mexico, sweeps round the shores of that Gulf, and issues with accelerated velocity towards the north, by the channel between the southern point of Florida and the Bahama Islands. It then rolls along the shore of North America, diminishing in velocity, but increasing in breadth, till it reaches the great bank of Newfoundland. There it suddenly turns towards the east and south-east, and flows with still decreasing velocity towards the shores of Europe, the Azores, and the coasts of France. Navigators readily distinguish it by the lighter temperature of its waters, their not being so dark in color, and the shores of snow which cover their surface. The celebrated Dr Franklin first caused it to be laid down on a map, and in his various voyages from America to Europe, made numerous observations on its peculiarities. Humboldt, in May 1804, observed its velocity in the twenty-seventh degree of latitude, and found it about eighty miles in twenty-four hours, though the north wind blew very strong at the time of the observation. When it issues from the Gulf of Florida, its velocity is moderate, in a torrent, and is sometimes five miles an hour, but at others is not more than a mile. At the nearest point of Florida and the bank of Bahama, the breadth is only fif-

teen leagues, but a few degrees further north it is seventeen; in the parallel of Charlestown, it is from forty to fifty leagues in breadth; and in latitude 40° 25', this is increased to nearly eighty leagues. The waters of the torrid zone, being thus forcibly impelled towards the north-east, preserve their high temperature to such a degree, that in latitude 40° and 41° it has been found to be 22.5° of the centigrade thermometer, or 72° of Fahrenheit; while out of the current the temperature of the water was only 63.5°. In the parallel of New York, the temperature of the gulf stream is equal to that of the sea in latitude 80°. When the stream reaches the western Azore island, where the breadth is about 160 leagues, the waters still preserve a part of the impulsion they received in the Gulf of Florida, nearly 1000 leagues distant. Thence it proceeds to the Canaries and the coast of Africa, and in the latitude of Cape Blanco, where the waters flow towards the south-west, they mingle with the current of the tropics, and recommence their tour from east to west.

Thus it appears that the waters of the Atlantic, between the eleventh and forty-third degrees, are constantly drawn by currents into a kind of whirlpool; and if a body floating on these waters be supposed to return precisely to the place from which it commenced its motion, M. Humboldt has calculated, from the known velocity of the current, that it would require two years and ten months to complete its circuit of 3800 leagues. 'A boat,' he observes, 'which may be supposed to receive no impulsion from the winds, would require thirteen months from the Canary islands, to reach the coast of Caraccas, ten months to make the tour of the Gulf of Mexico and reach Tortoise shoals, opposite the port of Havannah, while forty or fifty days might be sufficient to carry it from the Straits of Florida to the banks of Newfoundland. Estimating the velocity of the water at seven or eight miles in twenty-four hours, in their progress from this bank to the coast of Africa, it would require ten or eleven months for this last distance. Such are the effects of this slow but regular motion, which agitates the waters of the ocean.' A branch of this current evidently reaches the western shores of Europe, as the productions of the tropical regions of America are frequently thrown on the coasts of the Hebrides, Scotland, and Norway.

M. Humboldt endeavoured to ascertain the comparative height of the waters of this ocean along its shores. In reference to the Gulf of Mexico, and the opposite side of the isthmus on the shores of the Pacific, he found the surface of the former to be six or seven metres higher than that of the latter. The depth of the Atlantic is also extremely various; in many places being wholly beyond the power of man to fathom. Captain Scoresby, in the Greenland sea, in 1817, plumbed to the greatest known depth which a line has reached, i. e. 7200 feet. Many parts of the Atlantic, however, are thought to be three times this depth.

The saltness and specific gravity of the Atlantic differ in various parts; and gradually diminish from the equator to the poles. In the neighbourhood of the British isles, the salt has been

stated at $\frac{1}{3}$ rd of the weight of the water; and Dr. Thompson, in his Chemistry, observes, that as far as experience has gone, the proportion of saline contents does not appear to differ much, whatever may be the latitude in which the water is examined. Captain Phipps, in north latitude 30°, and sixty fathoms under ice, found the saline contents of sea-water to be 0.0354; in latitude 74°, he found them to be 0.036; in latitude 60°, 0.034. Pages found sea-water, taken up in north latitude 45° and 39°, to contain 0.04 of saline contents; and Baumé, obtained by analysis from water taken up by Pages, in north latitude 34° and 14°, exactly the same proportion of saline matter. In southern latitudes, Pages found the following proportions of saline contents, viz.:

Latitude	Sal. Matter	Latitude	Sal. Mat.
49° 50'	0.0416	25° 54'	0.04
46 0	0.045	20 00	0.039
40 30	0.040	1 16	0.035

The specific gravity of the water is greatest where the saline ingredients contained are the most abundant; as it is the mixture of these with the pure water that increases its weight.

The water of the Atlantic ocean is warmest between 5° 45' and 6° 15' of north latitude, where it has been found by actual observation to vary from about 82° 5' to 84° 5' of Fahrenheit's thermometer. There, too, the temperature of the sea is generally a few degrees higher than that of the air which reposes upon it. Nearer the poles the influence of the seasons on the surface of the ocean, becomes more sensible; but, as the temperature of the water changes more slowly than that of the atmosphere, the means do not, in point of time, exactly correspond. Where not disturbed by local causes, the mean temperature of the surface water is not very different from that of the incumbent atmosphere. It is about 81° at the equator, 70° at 26° of north latitude, and 60° at 45°. The temperature diminishes as the depth increases. M. Peron found that at the depth of 380 fathoms, the temperature was only 45° 5', though at the surface it was 80°. Currents greatly modify the temperature by transmitting the water of one region to another, as well as in some degree by the agitation they create. While the current which sets into the Gulf of Mexico is much warmer than the adjacent parts of the sea, it is not so warm as that which flows through Magellan's Straits into the Pacific.

Humboldt made various experiments on the surface of the Atlantic Ocean, between the 9th of June and the 15th of July, 1799, from which the following are selected:

North lat.	West lon.	Temperature of the Atlantic ocean, at its surface.
39 10	16 18	59 00 Fahrenheit
34 30	16 55	61 34
32 16	17 4	63 86
30 36	16 54	65 48
29 18	16 40	66 74
26 51	19 13	68 00
20 8	28 51	70 16

17 57	33 14	72 32
14 57	44 40	74 66
13 51	49 43	76 46
10 46	60 54	78 44

He farther remarks that, 'from Corunna to the mouth of the Tagus, the water of the sea varied but little in its temperature; but from the thirty-ninth degree of latitude to the tenth, the increment was very sensible and very constant, though not always uniform. From the parallel of Cape Montego to that of Salvage, the progress of the thermometer was almost as rapid as from 20° 18' to 10° 46'; but it slackened extremely at the limits of the torrid zone, from 29° 18' to 20° 8'. This inequality is, no doubt, caused by the currents that mingle the waters of different latitudes, and which, as we approach the Canary Islands, or the coast of Guiana, set either to the south-east, or north-west. M. de Churrua, who crossed the equator in his voyage to the straits of Magellan, in the twenty-fifth degree of west longitude (in October), found the maximum of the temperature of the Atlantic ocean, at the surface in 6° of north latitude.' *Humboldt's Personal Narrative.*

Masses of ice, and icebergs, having their origin in high latitudes, are carried towards the south and south-west by the general current, which flows from the poles towards the equator; and they have a great influence in lowering the summer temperature both of the ocean and atmosphere. Fragments of these icebergs occasionally reach the fortieth degree of latitude. At 50° the rivers, lakes, and bays, of the sea, sometimes freeze; and at 60°, the gulfs and interior seas sometimes freeze in their whole extent.

ATLANTIDES, in astronomy, the Pleiades, or seven stars, so called, as being supposed to have been the daughters of Atlas, who, the poets fabled, were translated into heaven.

ATLANTIS, ATALANTIS, or ATLANTICA; an island mentioned by Plato and some others of the ancients, concerning the real existence of which there have been many disputes. Homer, Horace, and the other poets, make two Atlanticas, calling them Hesperides and Elysian Fields, making them the habitations of the blessed. The most distinct account of this island we have in Plato's *Timæus*, of which Mr. Chambers gives the following abridgement. 'The Atlantis was a large island in the western ocean, situated opposite to the straits of Gades. Out of this island there was an easy passage into some others, which lay near a large continent, exceeding in bigness all Europe and Asia. Neptune settled in this island, from whose son, Atlas, its name was derived, and divided it among his ten sons. To the youngest fell the extremity of the island, called Gadir; which, in the language of the country, signifies fertile, or abundant in sheep. The descendants of Neptune reigned here from father to son for a great number of generations in the order of primogeniture, during the space of 9000 years. They also possessed several other islands; and, passing into Europe and Africa, subdued all Lybia as far as Egypt, and all Europe to Asia Minor. At length the island sunk under water: and for a long time after-

wards the sea thereabouts was full of rocks and shelves.' Many of the moderns also are of opinion, that the existence of the Atlantis is not to be looked upon as entirely fabulous. Some take it to have been America; and from thence, as well as from a passage in Seneca's *Medea*, and some other obscure hints, they imagine that the new world was not unknown to the ancients. But allowing this to be the case, the above-mentioned continent, which was said to lie beyond Atlantis, would seem rather to have been the continent of America than that of Atlantis itself. The learned Rudbeck, professor in the University of Upsal, in a work entitled *Atlantica sive Manheim*, endeavours to prove that Sweden and Norway are the Atlantis of the ancients; but this its situation will not allow us to believe. By Kircher it is supposed to have been an island extending from the Canaries to the Azores; that it was swallowed up by the ocean, as Plato asserts; and that these small islands are the shattered remains of it.

ATLAS, one of the Titans, son of Japetus and Clymene, one of the Oceanides. He was brother to Epimetheus, Prometheus, and Menætius. He married Pleione, daughter of Oceanus, or Hesperis, according to others, by whom he had seven daughters, called Atlantides. He was king of Mauritania, and master of a thousand flocks; as also of beautiful gardens, abounding in fruit, which he entrusted to the care of a dragon. Perseus, after the conquest of the Gorgons, passed by the palace of Atlas, and demanded hospitality. The king, who had been informed by Themis that he should be dethroned by one of the descendants of Jupiter, refused to receive him. Perseus showed him Medusa's head, and Atlas was instantly changed into a large mountain. This mountain which runs across the deserts of Africa, east and west, is so high that the ancients have imagined that the heavens rested on its top, and that Atlas supported the world on his shoulders. Pygmaeus says, that Atlas assisted the giants in their wars against the gods, for which Jupiter compelled him to bear the heavens on his shoulders.

ATLAS, in anatomy, the name of the first vertebra of the neck, which supports the head. It has no spinal apophysis, because the motions of the head do not turn on this vertebra, but on the second.

ATLAS, in architecture, is a name given to those figures, or half figures, of men, sometimes used instead of columns, or pilasters, to support any member of architecture, as a balcony, or the like. These Atlantes are also called Telamones.

ATLAS, in commerce, a silk satin, manufactured in the East Indies. There are some plain, some striped, some flowered, the flowers of which are of gold, or silk. There are atlases of all colours; but most of them false, especially the red and crimson. The manufacture of them is, when of gold and silk being worked together in such a manner as no workman in Europe can imitate; yet they are far from having that fine lustre which the French know how to give to their silk stuffs. In the Chinese manufactures of this sort, they gild paper on one side with leaf-gold; then cut it in long slips, and

weave it into their silks; which makes them, with little cost, look very rich and fine. The same long slips are twisted about silk threads, so artificially, as to look finer than gold thread, though it be of no great value.

ATLAS, in geography, a lofty chain of mountains which separate Barbary from the great desert of Zaara. They are said to have derived their name from Atlas, king of Mauritania. The mountains which form the eastern boundary of the empire of Morocco are by far the loftiest part of this chain; their height rises to upwards of 13,000 feet; and their summits are covered with perpetual snow. As the chain stretches through eastern Barbary, it diminishes considerably in height, spreading into various branches. These Dr. Shaw represents as generally consisting of a number of little hills of the perpendicular height of 400 or 500 yards, covered with groves, and ranges of fruit and forest trees rising behind each other. From this chain numerous rivers descend and fertilise the plains of Morocco in their way to the ocean; while others flow southwards into the desert, till they are lost in its sands. The geology of the Atlas is very little known; but its basis is probably granite, while in its lower parts calcareous rocks appear to prevail. Considering its extent and magnitude, the Atlas does not produce any very copious supply of minerals. Lead and silver are obtained in considerable quantity, and farther to the south are mines of gold and silver, which the sovereigns of Morocco have prevented from being worked, from jealousy of the natives. Antimony, for which there exists an extensive demand as a cosmetic, is drawn very copiously from these mountains. The most valuable kind is found near Tafilet, and is called El Kahol Filelly. Opposite to Terodant, sulphur is found in immense quantities. Iron is also produced though not very abundantly. The ancients, whose knowledge of geography was very confined, conceived these mountains to be the pillars of the world, and that their summit upheld the heaven.

ATMOMETER, (from *ατμος*, vapor, and *μετρον*, a measure). An instrument invented by professor Leslie for ascertaining the quantity of moisture exhaled from a humid surface in a given time. It consists of a thin ball of porous earthenware, from one to three inches in diameter, having a small neck firmly cemented to a long wide glass tube, to which a brass case is adapted, with a close fitting collar of leather. Being filled with distilled water, the waste and descent of this column indicates the quantity of evaporation from the surface of the ball. The tube is marked downwards with lines, from 200 to 500 in number, corresponding to the rings of fluid that, if spread over the whole exhaling surface, would form a film 1000th of an inch in thickness. The cavity of the instrument is next to be filled with distilled water, and its cap secured tight, and then suspended in a situation exposed to wind, but not to rain. The water will transude through the porous matter of the ball as fast as it evaporates from the external surface; and the waste is measured by the corresponding descent of the liquid in the stem.

ATLITA, in entomology, a species of papilio, indented, brown, fulvous beneath, with undulated glaucous streaks, and five blind-eye shaped spots Native of the East Indies.

ATMOSPHERE, } From the Gr. *ατμος*,
ATMOSPHERICAL. } vapor, and *σφαира*,
 sphere. The body of air and vapor that surrounds the earth.

ATMOSPHERE; this word is used to signify the whole of the fluid mass consisting of air, aqueous and other vapors, electric fluids, &c. which surrounds the earth to a considerable height, and partakes of both its diurnal motion on its axis, and its annual motion round the sun. Its composition was, until within these few years, very little known. That it is a very heterogeneous mass, might readily be concluded, upon considering that it is the common receptacle of all the effluvia, exhalations, and particles, raised from innumerable bodies upon the earth: hence it has been compared to a vast chemical vessel in which the matter of all kinds of bodies is continually floating; and thus exposed to the action of the sun; from whence proceed innumerable operations, sublimations, separations, compositions, digestions, fermentations, putrefactions, &c. The discoveries of modern chemistry have, however, shown us its essential constituents and their proportions, a subject which we have treated at considerable length under the word **AIR**.

It only remains therefore for us to add a few supplementary observations to that paper; and these will principally respect the figure of the atmosphere and its supposed limits. If the earth had no diurnal rotation upon its axis, then according to the laws of gravity the atmosphere would be of an uniform height, enclosing the earth, which in this case would be perfectly spherical. But as the earth and the atmosphere revolve about an axis, the different parts of both have a centrifugal force, by which their gravity is diminished towards the equator, the figure of the atmosphere becomes an oblate spheroid; the parts that correspond to the equator being farther removed from the centre than the parts that correspond to the poles, and the ratio of the poles to the equatorial diameter, being as two to three. Besides, the figure of the atmosphere must on another account represent a flattened spheroid; namely, because the sun strikes more directly the air between the tropics, than the air in the polar regions, and hence the mass of atmospheric air adjoining the poles being less heated, cannot expand so much, nor reach so high as the air in the neighbourhood of the equator. And yet higher columns about the equatorial regions may not be heavier than those at the poles; seeing that the same force which contributes to elevate the air, diminishes its gravity and pressure on the surface of the earth.

Mr. Kirwan has given in the Transactions of the Royal Irish Academy an ingenious dissertation on the figure, height, weight, &c. of the atmosphere, where he observes, that in the natural state of the atmosphere, its weight must be equal over all the earth, and since the density of the air at the earth's surface increases from the equator to the poles, its height must diminish from the poles to the equator, and from this it

follows that although the equatorial air be less dense to a certain height than the polar, yet at some greater heights it must be more dense. Hence it is inferred that in the higher regions of the atmosphere, the denser equatorial air not being supported by the collateral extra-tropical columns, gradually flows over and rolls down to the north and south.

La Place, in that part of his *Système du Monde* which treats of the atmosphere of the planets, ingeniously observes, that in all the changes to which the atmosphere is subject, the sum of the products of the particles of the revolving body and its atmosphere, multiplied respectively by the areas they describe round the common centre of gravity (the radii being projected on the plane of the equator), remains the same in equal times. Supposing therefore by any cause whatever, the atmosphere should be contracted, or that part thereof should become condensed on the surface of the body, the rotatory motion of the latter and its atmosphere would be accelerated; for the radii vectores of the areas described by the particles of the original atmosphere becoming smaller, the sum of the products of all the particles by their corresponding areas cannot remain the same unless their velocities be augmented.

The limits of the atmosphere have been a frequent subject of philosophical inquiry, especially since it was discovered by the Torricellian tube that air is endued with weight and pressure. Indeed, if the air possessed no elastic power, but were everywhere of the same density, from the surface of the earth to the extreme limit of the atmosphere, like water, which is equally dense at all depths, the whole height of the atmosphere might be ascertained without difficulty. It has been well established, that the weight of a column of air reaching to the top of the atmosphere, is equal to the weight of the mercury contained in the barometer, and counterbalancing it; and the proportion of weight likewise being known between equal bulks of air and mercury, it will be easy to find the height of such a column, and consequently that of the atmosphere itself. For a column of air one inch high being to an equal column of mercury as 1 to 11364.6; it is evident that 11364.6 such columns of air, that is a column 947 feet high, would be equal in weight to one inch of mercury: and consequently the 30 inches of mercury sustained in the barometer, require a column of air 28,410 feet high; whence the height of the atmosphere would only be 28,410 feet, or little more than five English miles and a quarter high. But the air by its elastic property expands and contracts; and it being found by repeated experiments that the spaces it takes up when compressed by different weights, are reciprocally proportional to those weights themselves; or, that the air takes up the less space the more it is pressed; it follows that the air in the upper regions of the atmosphere, where the weight is so much less, must be much rarer than near the surface of the earth; and consequently that the height of the atmosphere must be much greater than is above assigned.

On this subject it has been further and well remarked, that if the earth were perfectly mo-

less, the elasticity of the atmosphere uniformly as the compressing force, and matter infinitely divisible, we could have no other than an atmosphere indefinitely extended; but the diurnal motion at a certain height brings the centrifugal force equal to that of gravity, and beyond this limit no atmosphere can exist. Its particles by the operation of this force would here become projected into space; and the process would continue until the entire atmosphere was dissipated. Dr. Wollaston, in an ingenious paper in Part I. of the Philosophical Transactions for 1822, observes, that if we admit that air has been rarefied so as to sustain only $\frac{1}{100}$ of an inch of barometrical pressure, and that this measure has afforded a true estimate of its rarity, we should infer from the law of elasticity observed within certain limits, that the atmosphere extends at least to the height of forty miles with properties yet unimpaired by extreme rarefaction. Beyond this limit we are left to conjecture, founded on the supposed divisibility of matter; and if this be infinite, so also must be the extent of the atmosphere, except so far as regards the centrifugal force to which we have already referred; for if the density be throughout as the compressing force, then must a stratum of given thickness at every height be compressed by a superincumbent atmosphere, bearing a constant ratio to its own weight, whatever be its distance from the earth. But if air consists of any ultimate particles no longer divisible, then must expansion of the medium composed of them cease at that distance where the force of gravity downwards upon a single particle is equal to the resistance arising from the repulsive force of the medium.

On the supposition of limited divisibility, the atmosphere which surrounds us must be conceived to be a medium of finite extent, and may be peculiar to our planet, since its properties would afford no ground to presume that similar matter exists in any other planet. But if we adopt the supposition of unlimited expansion, we must conceive the same kind of matter to pervade all space, where it would not be in equilibrium unless the sun, the moon, and all the planets possessed their respective shares of it condensed around them, in degrees depending upon their respective force of attraction, unless in those instances where the tendency to accumulation may be counteracted by the interference of other kinds of matter, or of other powers of which we have no experience, and concerning which we are not to be supposed to reason correctly.

None of these suppositions, since we know the mass and distance of the sun, equally lies in our power to be proved, or disproved; and the density of their respective strata, and the height of each, and what distance from the surface of each, the density would be the same as at the surface of the earth; which height, a sensible degree of refraction that is more than a degree, ought to be produced on a ray of light passing through it. For example, if the mass of the sun be conceived as that of our times that of the earth, the distance at which his force is equal to that of terrestrial gravity at our surface, will be 330 000 miles, or 175 times the earth's radius; and if his

radius be 111.5 times that of the earth then the distance will be $\frac{575}{111.5} = 5.15$ times the sun's radius. Now the mean apparent semi-diameter of the sun being $15'49''$, we have $15'49'' \times 5.15 = 1^\circ 21' 29''$, for the distance from the sun's centre, where the refractive power of his atmosphere is equal to that at the earth's surface; that is where it would produce a deviation of a degree to a ray passing through it at that distance. We are able, as Dr. Wollaston has shown, to observe Venus within this distance of the sun; and since in this observation we find no effect produced by refraction, the observed and computed places agreeing to a fraction of a minute, we have a right to infer that at the distance we have computed, the density of the sun's atmosphere is not such as it would be if each body in the system possessed an atmosphere proportional to its own attractive power; but this must be the case if the elastic matter of the atmosphere were infinitely divisible, hence then again we may conclude that matter is not infinitely divisible, and consequently that the atmosphere of this earth is of a finite and limited height, and may be peculiar to it. But some doubt will hang over this deduction in respect to the sun, on account of the probable heat near his surface, which may produce a rarefaction far exceeding any thing that we can form an idea of; but this will not be the case if we select Jupiter as the body for observation.

Since the mass of Jupiter is full 309 times that of the earth, the distance at which his attraction is equal to gravity must be about $\sqrt{309}$, or 17.6 times the earth's radius; and since his diameter is nearly 11 times greater than that of the earth, we shall have $\frac{17.6}{11} = 1.6$ times his own radius; for the distance from his centre at which an atmosphere equal to our own should occasion a refraction exceeding one degree to the fourth satellite. This distance would subtend an angle of about $3^\circ 37'$, so that an increase of density to $3\frac{1}{2}$ times our common atmosphere, would be more than sufficient to render the fourth satellite visible to us when behind the centre of the planet; and consequently to make it appear on both or all sides at the same time. Hence, whatever doubt may remain on the deduction made from observations on Venus seen through the solar atmosphere, in consequence of the possible effects of heat which cannot be appreciated, it is evident that no error from this source can be apprehended in regard to Jupiter. This planet therefore does not possess an atmosphere proportional to his mass, as he would do if the matter composing it were infinitely divisible, and therefore, as we have seen, common to the whole solar system. Hence then we have a right to conclude, that matter is not infinitely divisible, and that each planet possesses an atmosphere peculiar to itself of limited height, composed of ultimate atoms of definite magnitude, no longer divisible by the repulsion of their parts.

We may, in conclusion, observe that to the refractive and attractive power of the atmosphere we owe all the blessings and phenomena of twilight. By the former the rays of light are

bent from the right-lined direction, by the latter objects are enlightened more uniformly on all sides. The want of this power would occasion a strange alteration in the appearance of things; shadows would be totally dark, and the enlightened sides of objects overpoweringly bright; so that probably we could see no more of them than their bright halves; and for a view of the other halves must turn them round, or, if immovable, wait until the sun could come round upon them. Such a pellucid unreflective atmosphere might be very commodious for astronomical observations on the course of the sun and planets among the fixed stars visible by day as well as by night; but such a sudden transition from darkness to light, and from light to darkness immediately upon the rising and setting of the sun, without any twilight, and even upon turning to or from the sun at noon day, would be very inconvenient and offensive to our eyes. See *Keil's Astron. Lect. 20, &c.* See also LIGHT and REFRACTION in our alphabet.

ATOLLENS OCULI, in anatomy, a name given by Albinus to one of his quatuor recti musculi oculi. This is the muscle called by Molinett, and others, the superbus, and by Cowper, the elevator oculi.

ATOM, } From *a*, privative, and *τεμνω*, to cut. Something so small
ATOMICAL, }
ATOMIST, } as not to be cut into smaller
ATOMLIKE, } particles; so simple as not to
ATOMOLOGY, } be capable of reduction to
ATOMY. } simpler elements.

It is as easy to count *atoms*, as to resolve the propositions of a lover. *Shakespeare. As You Like it.*

Drawn with a team of little *atomies*,

Athwart men's noses, as they lie asleep.

Shakespeare.

Vitrified and pellucid bodies are clearer in their consistencies, than in powders and *atomical* divisions.

Brown's Vulgar Errors.

These *atomic* theists utterly evacuate that grand argument for a God, taken from the phenomenon of the artificial frame of things, which has been so much insisted upon in all ages.

Cudworth's Intellectual System.

Innumerable minute bodies are called *atoms*; because, by reason of their perfect solidity, they were really indivisible. *Ray.*

ATOMIC THEORY. A species of philosophy recently introduced into chemistry, and founded on the axiom, "that chemical union consists in the combination of the atoms of bodies with each other;" so that, when two bodies chemically unite and form a third body, the two substances united are dispersed every where through the new compound. Thus saltpetre is a compound of nitric acid and potash; and, if we examine so small a portion of this salt as the 100th part of a grain, it will be found to be compounded of these two substances, nitric acid and potash: and if any part had not these constituents, it would not be saltpetre. See ATTRACTION.

ATONE, *v. & ad.* } To be *at one*. Imply
ATONEMENT, } ing a state of former
ATONEMAKER, } estrangement, and expressing present reconciliation. To satisfy the

claims of justice and equity by making reparation and expiation; to enjoy the renewed friendship and regard of the injured party.

Paul sayth, I Timothy ii. One God, one Mediator (that is to say, advocate, intercessor, or an *atone-maker*), betwene God and man; the man Christ Jesus which gaue himselfe a ransom for all men.

The Whole Works of W. Tyndall, fol. 158. c. i.

He seeks, to make *atone*ment,

Between the duke of Glo'ster and your brothers.

Shakspeare.

He and Aufidius can no more *atone*,

Than *atone*ment contrariety. *Id. Coriolanus.*

From a mean stock, the pious Decii came;

Yet such their virtues, that their loss alone,

For Rome and all our legions, did *atone*.

Dryden. Juvenal.

The good intention of a man of weight and worth, or a real friend, seldom *atones* for the uneasiness produced by his grave representations *Locke.*

Let thy sublime meridian course

For Mary's setting rays *atone* :

Our lustre, with redoubled force,

Must now proceed from thee alone. *Prior.*

His virgin sword Ægysthus' veins imbrued;

The murd'rer fell, and blood *atone'd* for blood.

Pope.

Soon should you boasters cease their haughty strife; Or each *atone* his guilty love, with life. *Id.*

And the Levites were purified; and Aaron made an *atone*ment for them, to cleanse them. *Numbers.*

Surely, it is not a sufficient *atone*ment for the writers; that they profess loyalty to the government, and sprinkle some arguments in favour of the dissenters; and, under the shelter of popular politics and religion, undermine the foundations of all piety and virtue. *Swift.*

If any contention arose, he knew none fitter to be their judge, to *atone*, and make up their quarrels, but himself. *Drummond.*

ATONEMENT. The word *כפר*, translated *atone*ment in the sacred writings, some writers say, signifies covering; and thus it would seem to imply that man can only be *at-one* with an infinitely just God, when that for which his progenitor was banished God's presence, and that which he has himself acquired by following a similar course, is covered. See EXPIATION and SACRIFICE.

ATONICS, in grammar, words unaccented.

ATONY; from *a*, and *tonos*, tone; in medicine, a defect of tone or tension, or a laxity or debility of the solids of the body.

ATOOI, one of the Sandwich islands.—Towards the north-west and north-east the face of the country is ragged and broken; but to the southward it is more even. The hills rise from the sea side with a gentle acclivity, and, at a little distance back, are covered with wood. Its produce is the same with that of the other islands of this cluster; but its plantations are managed much better than those of all the neighbouring islands. In the low grounds, contiguous to the bay wherein our navigators anchored, they were regularly divided by deep ditches; the fences were formed with a neatness approaching to elegance, and the roads through them were finished in such a manner as would have reflected credit even on an European engineer. The anchoring place, which our vessel occupied, is on the south-west side of the island, about two

leagues from the west end, before a village named Wymoa. As far as was sounded, the bank was free from rocks, except to the eastward of the village, where there projects a shoal, on which are some rocks and breakers. This road is somewhat exposed to the trade wind, notwithstanding which defect, it is far from being a bad station, and greatly superior to those which necessity continually obliges ships to use, in countries where the winds are not only more variable, but more boisterous; as at Madeira, Teneriffe, the Azores, &c. The landing too is not so difficult as at most of those places; and, unless in very bad weather, is always practicable. The water in the neighbourhood is excellent, and may be conveyed with ease to the boats. But no wood can be cut at any convenient distance, unless the islanders could be prevailed upon to part with the few etooa trees (*cordia sebestiina*) that grow about their villages, or a species called dooe dooe, which grows farther up the country. Atooi is about 300 miles in circumference. Long. 200° 20' E., lat. 21° 57' N.

The natives of Atooi are of the middle size, and in general stoutly made. They are neither remarkable for a beautiful shape nor for striking features. Their visage, particularly that of the women, is sometimes round, but others have it long; nor can it justly be said that they are distinguished as a nation by any general cast of countenance. Their complexion is nearly of a nut brown; but some individuals are of a darker hue. They are far from being ugly, and have, to all appearance, few natural deformities of any kind. Their skin is not very soft nor shining; but their eyes and teeth are, for the most part, pretty good. Their hair in general is straight; and though its natural color is usually black, they stain it, as at the Friendly and other Islands. They are a true, vigorous, and most expert swimmers, laying their canoes upon the most frivolous occasion, diving under them and swimming to others, though at a considerable distance. Women with infants at the breast, when the surf was so high, as to prevent their landing in the canoes, frequently leapt overboard, and swam to the shore without endangering their little ones. They appeared to be of a frank cheerful disposition, and are equally free from the rickety levity which characterises the inhabitants of Orkney, and the sedate cast which is observable among many of those of Tongataboo. They seem to cultivate a sociable intercourse with each other; and except the propensity to fighting, which is as it were innate in most of the people in those seas, they appeared extremely friendly. It was pleasing to observe with what affection the women managed their infants, and with what alacrity the men contributed their assistance in such a tender office; thus distinguishing themselves from those savages who consider a wife and child as things rather necessary than desirable, or worthy of their regard and esteem. From the numbers that were seen assembled at every village, in coasting along, it was conjectured that the inhabitants of this island are pretty numerous. Including the straggling houses, it was computed there might perhaps be, in the whole island, sixty such villages as that near

which our ships anchored; and, allowing five persons to each house, there would be in every village 500, or 30,000 in all upon the island. This is by no means exaggerated; for there were sometimes 3000 people at least collected upon the beach, when it could not be supposed that above a tenth part of the natives were present.

The ground, from the wooded part to the sea, is covered with an excellent kind of grass, about two feet in height, which sometimes grows in tufts, and appeared capable of being converted into abundant crops of fine hay. But on this extensive spot not even a shrub grows naturally. Besides taro, the sweet potatoe, and other similar vegetables used by our crews as refreshments, among which were at least five or six varieties of plantains, the island produces bread fruit; which, however, seems to be scarce. There are also a few cocoa palms; some yams; the kappe of the Friendly Islands, or Virginian arum; the etooa tree, and odoriferous gardenia or cape jasmine. Our people also met with several trees of the dooe dooe, that bear the oily nuts, which are stuck upon a kind of skewer, and made use of as candles. There is a species of sida, or Indian mallow; also the morinda citrifolia, which is here called *none*; a species of *convolvulus*; the ava or intoxicating pepper, besides great quantities of gourds. These last grow to a very large size, and are of a remarkable variety of shapes, which are perhaps the effect of art. The scarlet birds, which were brought for sale, were never met with alive; except one small one, about the size of a canary bird, of a deep crimson color. A large owl, two brown hawks or kites, and a wild duck, were also seen. Other birds were mentioned by the natives; among which were the otoo, or bluish heron, and the torata, a sort of whimbrel. It is probable that this species of birds are numerous, if we may judge by the quantity of fine yellow, green, and small, velvet like, blackish feathers, used upon the cloaks and other ornaments worn by these people. Fish, and other productions of the sea, were to appearance not various. The only tame or domestic animals found here were hogs, dogs, and fowls, which were all of the same kind that had been met with at the islands of the South Pacific. There were also small lizards, and some rats.

ATOP. On top, at the top. See Top.

Atop whereof, but far more rich, appear'd
The work, as of a kingly palace-gate.

Paradise Lost.

What is extracted by water from coffee is the oil, which often swims *atop* of the decoction.

Arbutnot on Aliment.

ATRA BILIS, black bile, or melancholy. According to the ancients it hath a two-fold origin: first, from the grosser parts of the blood, and this they called the melancholy humor. Second, from yellow bile being highly concocted. Dr. Percival, in his *Essays Medical and Experimental*, suggests that it is the gall, rendered acrid by a stagnation in the gall-bladder, and rendered viscid by the absorption of all its fluid parts. Bile in this state discharged into the duodenum, occasions universal disturbance and disorder until it is evacuated; it occasions violent vomiting or purging, or both; and, previous

to this, the pulse is quick, the head aches, a delirium comes on, a hiccough, intense thirst, inward heat, and a fetid breath. Some describe this kind of bile as being acid, harsh, corroding, and, when poured on the ground, bubbling up, and raising the earth, after the manner of a ferment. Dr. Percival says, that by the use of the infus. senæ limoniât., warmed with the tinct. columb., he had checked the vomitings occasioned by this matter.

ATRACTOCERUS, in entomology, a genus of the order coleoptera, and family malacodermi. Its generic characters are: antennæ simple, and fusiform; short elytra, and sub-quadrate thorax. There is but one species, *A. necydaloides*, the *necydalis brevicornis* of Linnæus.

ATRACTYLIS, distaff thistle, a genus of the polygamia æqualis order, and syngenesia class of plants. Its generic characters are: CAL. many leaved: COR. compound radiate: STAM. five filaments; cylindrical anther: PIST. germen very short; style filiform; stigma bifid: PER. none: SEEDS turbinate. The species are: 1. *A. cancellata*, or small cnicus, an annual plant, rising about eight or nine inches high, with a slender stem, garnished with hoary leaves, having spines on their edges. 2. A gummifera, or prickly gum-bearing cnicus, known among physicians by the name of carline thistle, is a perennial plant. It sends out many narrow leaves, which are armed with spines on their edges, and lie close on the ground; between them the flower is situated, without a stalk, and having many florets enclosed in a prickly empalement. Its roots were formerly used as a warm diaphoretic and alexipharmic; but never came much into use in Britain, and the present practice has entirely rejected them. 3. *A. humilis*, or purple prickly cnicus, a perennial plant, rising about a foot high, with indented leaves, having small spines on their edges. All these plants are natives of the warm parts of Europe, as Spain, Sicily, and the Archipelago islands.

ATRA DIES, in antiquity. The word literally imports a black day; a denomination taken from the color, which is the emblem of death and mourning. Whence the Thracians had a custom of marking all their happy days with white stones or calculi, and their unhappy days with black ones; which they cast, at the close of each day, into an urn. At the person's death the stones were taken out; and, from a comparison of the numbers of each complexion, a judgment was made of the felicity or infelicity of his course of life. The dies atræ, or atrî, were denominated nefasti, and posterî. Such, in particular, was the day when the tribunes were defeated by the Gauls at the river Allia, and lost the city; also that whereon the battle of Cannæ was fought; and several others marked in the Roman calendar as atræ or unfortunate.

ATRAGENE, in botany, a genus of plants, class polyandria, order polygnia. Its generic characters are: CAL. four-leaved perianth: COR. twelve petals: STAM. filaments very many; oblong antheræ: PIST. germen many; villose style; stigma simple: PER. none: SEEDS very many. The species are shrubs, as *atragene japonica*, *atragene alpina*, &c.

ATRAMENT'AL, } Lat. *atramentum*, ink.
ATRAMENT'OUS. } Having the blackening property of ink.

If we enquire, in what part of vitriol this *atramental* and denigrating condition lodgeth; it will seem, especially to lie in the more fixed tult thereof.

Brown's Vulgar Errors.
I am not satisfied, that those black and *atramentous* spots, which seem to represent them, are ocular.

Brown.

ATRAPHAXIS, in botany, a genus of the digynia order and class of plants; natural order, twelfth, holoraceæ. CAL. two leaves; the petals are two, and sinuated; stigmas capitate; and there is but one seed. There are two species, both natives of warm countries

ATRATUS (Hugh), was born at Evesham, in Worcestershire. He made such proficiency in the knowledge of the sciences, particularly mathematics, medicine, and philosophy, that he was called the phoenix of the age. Pope Martin II. gave him a cardinal's hat in 1281. He died of the plague in 1287. He wrote *Genealogiis Humanis Problematâ*; and also *Canones Medicinalis*.

ATRA X, in fabulous history, a son of Ætolus, or, as others say, of the river Peneus. He was king of Thessaly, and built a town which he named *Atrax* or *Atracia*; which became so famous that the word *Atracius* was commonly given to an inhabitant of Thessaly. He was the father of that Hippodamia who married Pirithous, and who must not be confounded with the wife of Pelops, who was so named.

ATREBATES, the ancient inhabitants of Gallia Belgica, who possessed that part of Gaul now called Artois. A colony of them settled in Britain. They are mentioned by Cæsar among the nations which composed the Belgic confederacy against him; and the quota of troops which they engaged to furnish on that occasion was 15,000.

ATREBATES, or **ATREBATIOI**, a people of Britain, seated next to the Bibroci, in part of Berkshire, and Oxfordshire; and one of those Belgic colonies which came out of Gaul into Britain, and there retained their ancient name. Comius of Arras was a king or chieftain among the Atrebates in Gaul, in Cæsar's time: and he seems to have possessed some authority over our Atrebatii in Britain; for he was sent by Cæsar to persuade them to submission. This circumstance makes it probable that this colony of the Atrebatii had not been settled in Britain very long before that time. The Atrebatii were among those British tribes which submitted to Cæsar; nor do we hear of any remarkable resistance they made against the Romans, at their next invasion, under Claudius.

ATRESIA; from *a*, and *τραω*, whence *τραωω*, to perforate; in medicine, imperforation, or the state of those persons who want some natural aperture.

ATRETI, those persons of either sex in whom the anus, or genitals, are imperforate, whether naturally, or occasioned by some accident or disease; as the growth of some fleshy excrescence, or membrane, which stops the orifice

ATREUS, in fabulous history, the supposed

king of Mycenæ and Argos, about A. A. C. 1228. He was the son of Pelops by Hippodamia, and brother to Pittheus, Troezen, Thyestes, and Chrysippus. The latter being an illegitimate son, and a favorite with his father, Hippodamia resolved to remove him; and for this purpose she endeavoured to persuade Thyestes and Atreus to murder him; but her arguments proving vain, she executed it herself. Pelops was grieved at his son's death; and the brothers being suspected, they fled from his presence. Atreus retired to the court of his nephew, Eurystheus king of Argos, on whose death he succeeded to that throne. Some writers say he married Ærope, his predecessor's daughter, by whom he had Plisthenes, Menelaus, and Agamemnon; but, according to others, Ærope was the wife of Plisthenes, by whom she had Agamemnon and Menelaus, who are the reputed sons of Atreus, because he took care of their education, and brought them up as his own. Thyestes had followed his brother to Argos, where he lived with him, and debauched his wife, by whom he had some children. When Atreus discovered this incestuous commerce, he banished his brother from his court; but, determined to have more ample revenge for the violence offered to his bed, he soon after recalled him, and invited him to a sumptuous feast. Thyestes was served up with the flesh of the children he had by his sister-in-law the queen; and, when the entertainment was over, to convince him of what he had feasted upon, the arms and the heels of the murdered children were shown him. This action appeared so horrid that the sun is said to have withdrawn his light. Thyestes fled directly to the court of Theseus, and thence to Sicily, where he ravished his own daughter Pelopea, in a grove sacred to Minerva, not knowing who she was; though some say he committed this incest intentionally, to revenge himself on his brother Atreus, as the oracle had promised him satisfaction for the cruelties he had suffered, only by the hand of a son by himself with his own daughter. Pelopea brought forth a son whom she named Egisthus, and soon after she married Atreus, who had lost his wife. Atreus adopted Egisthus, and sent him to murder Thyestes, who had been made prisoner. Thyestes knew his son, and made himself known to him; when, instead of murdering his father, he espoused his cause, and avenged his wrongs by returning to Atreus and assassinating him.

ATRI, or **ATRIA**, a town of Italy, in Abruzzo, in Naples. It lies 26 miles west of Aquila, and was the birth place of the emperor Adrian. It is the see of a bishop, and is seated on a craggy mountain, five miles from the Adriatic sea. Long. 15 20 E., lat. 42 40' N.

ATRICAPILLA, in ornithology, a little bird, commonly known by the name of the black cap, and called, by some authors, *ficodala*, *scyalis*, or *melanchoroplus*, and by the Italians, *caponegro*.

ATRICES, or **ATRICI**, in medicine, small tubercles about the anus, which sometimes disappear, and then return again, at least in their early state. They are ranked in the number of condylomata, or *fici*. Some authors also give the denomination *atrici* to a kind of latent wounds

in the extremity of the rectum, which however do not perforate it.

ATRICILLA, in ichtthyology, a species of the *larus*.

ATRIDES, a patronymic of Agamemnon and Menelaus, the sons of Atreus.

ATRIENSES, in antiquity, a kind of servants in the great families at Rome, who had the care of the atria, and the things lodged therein. See **ATRIUM**. They were also called *atriarii*, though some make a distinction between *atrienses* and *atriarii*; suggesting, that the latter were an inferior order of servants, employed in the more servile offices of the atrium, as to attend at the door, sweep the area, &c. and to assist the former. The *atrienses* are represented as servants who had command over the rest, and acted as agents for their master, in selling his goods, &c. To their care were committed the images of the master's ancestors, &c. which were placed round the atrium; and which they carried in procession at funerals, &c. In the country houses, the *atrienses* had the care of the other furniture and utensils, particularly those of metal, which they were to keep from rust. Other things they were to hang in the sun, to keep them dry, &c. They were clothed in a short white linen habit, to distinguish them, and prevent their loitering from home.

ATRIP, in nautical language, is applied either to the anchor or sails. The anchor is *atrip*, when it is drawn out of the ground, in a perpendicular direction, either by the cable or buoy rope. The top sails are *atrip*, when they are hoisted up to the mast head, or to their utmost extent.

ATRIplex, **ORACH**, or **ARRACH**, a genus of the monœcial order and polygama class of plants; natural order twelfth, *holoraceæ*. **CAL.** the hermaphrodite flower, five-leaved; **cor.** none; **STAM.** five; **STY.** bifid; **SEED**, one, depressed. There are fourteen species, of which the following are the most remarkable: 1. *A. halimus*, the broad leafed orach, formerly cultivated in gardens as a shrub, by some formed into hedges, and constantly sheared to keep them thick. It may be propagated by cuttings, and planted in any of the summer months, in a shady border; where they will soon take root, and be fit against the following Michaelmas to transplant. 2. *A. hortensis*, the garden orach, was formerly cultivated in gardens, and used as a substitute for spinach. There are three or four varieties of this plant, whose only difference is their color; one is a deep green, another a dark purple, and a third has green leaves and purple borders. They are all annual, and must be propagated by seeds. These are to be sown at Michaelmas, soon after they are ripe. This species is an article of the *materia medica*; a decoction of the leaves is recommended in costiveness where the patient is of a hot bilious disposition. 3. *A. petulacoides*, the shrubby sea orach, grows wild by the sea side, in many places of Britain. It is a low under shrub, seldom rising above two feet and a half, or at most three feet high; but becomes very bushy.

ATRIUM, in antiquity, the large room or court at the first entrance into the house, in which the Romans used to sup, and in which they kept

the statues and images of their ancestors. In ecclesiastical antiquity it signified an open place or court before a church, making part of what was called the narthex, or antetemple. The atrium in the ancient churches was a large area or square plat of ground, surrounded with a portico or cloister, situate between the porch or vestibule of the church and the body of the church. Some have mistakenly confounded the atrium with the porch or vestibule, from which it was distinct; others with the narthex, of which it was only a part. The atrium was the mansion of those who were not suffered to enter farther into the church. More particularly, it was the place where the first class of penitents stood to beg the prayers of the faithful, as they went into the church. Atrium, in the canon law, the cemetery or church yard. In this sense, we find a law, prohibiting buildings to be raised in atrio ecclesie, except for the clergy; which the glossary explains thus, id est in cemetery, which includes the space of forty paces around a large church, or thirty round a small church or chapel.

ATRO'CIOUS, } Lat. *atrox*. Perhaps a,
 ATRO'CIOUSLY, } intente, and *trux*, fierce,
 ATRO'CIOUSNESS, } savage, rough in manners.
 ATRO'CITY. } Used in the sense of inflexible, terrible, dreadful, enormously wicked.

An advocate is necessary; and therefore audience ought not to be denied him in defending causes, unless it be an atrocious offence. *Ayliffe's Parergon*.

I never recal it to mind, without a deep astonishment of the very horror and atrocity of the fact in a Christian court. *Wotton*.

They desired justice might be done upon offenders, as the atrocity of their crimes deserved. *Clarendon*.

Bad as Herod was, the petition of Salome at first shocked him. 'The king was sorry.' He thought of John's character, the atrociousness of the murder, and the opinion which the world would entertain of the murderer.

Horne on the Life and Death of St. John the Baptist.

ATROPA, DEADLY NIGHT-SHADE: A genus of the monogynia order, and pentandria class of plants; natural order twenty-fifth, *Luridæ*. The corolla is campanulated; the stamina are distant; the berry is globular, and consisting of two cells. There are eight species; the most common are: 1. *A. belladonna*, growing wild in many parts of Britain. It hath a perennial root, which sends out strong herbaceous stalks of a purplish color. These rise to the height of four or five feet, garnished with entire oblong leaves, which, towards autumn, change to a purplish color. The flowers are large, and come out singly between the leaves upon long foot stalks; bell-shaped, and of a dusky color on the outside, but purplish within. After the flower is past, the germen turns to a red berry, a little flattened at the top, about the size of a cherry. It is first green; but when ripe, turns to a shining black, sits close upon the empalement, and contains a purple juice of a nauseous sweet taste, and full of small kidney-shaped seeds. This species being remarkable for its poisonous qualities, is very seldom admitted into gardens, nor should it ever be cultivated or allowed to grow in those places to which children have access. The symptoms produced by this poison are vertigo, delirium,

great thirst, painful deglutition, and retching, followed by furor, stridor dentium, and convulsions; the eye-lids are drawn down, the uvea dilated and immovable, the face becomes red and tumid, and spasms affect the mouth and jaw; the sensibility and irritability of the body suffer such great diminution, that large and repeated doses of the strongest emetics produce no sensible effect; the pulse is small, hard, quick; and subsultus tendinum, risus sardonius, and *coma*, close the fatal scene. Vinegar liberally drank has been found most efficacious in obviating the effects of this poison. The leaves of the *belladonna* were first used externally to discuss scirrhus and cancerous tumors, and as an application to ill-conditioned ulcers; and their good effects in this way at length induced physicians to employ them internally for the same disorders; and we find a considerable number of well-authenticated facts, which prove them to have been of important service. 2. *A. frutescens*, is a native of Spain, and rises with a shrubby stem to the height of six or eight feet; dividing into many branches, garnished with round leaves, in shape like those of the storax tree: these are placed alternately on the branches. The flowers come out between the leaves, on short foot stalks, shaped like those of the former, but much less; of a dirty yellowish color, with a few brown stripes; but these are never succeeded by berries in Britain. 3. A herbacea, is a native of Campeachy, and has an herbaceous stalk and a perennial root, which puts forth several channelled herbaceous stalks, rising about two feet. Towards the top they divide into two or three small branches, garnished with oval leaves, four inches long, and three broad, having several prominent transverse ribs on their under side. The flowers come out from between the leaves; on short foot stalks; they are white, and shaped like those of the common sort, but smaller. It flowers in July and August, but seldom ripens its fruit in Britain. 4. A *mandragora*, the mandrake, has been distinguished into the male and female. The male mandrake has a very large, long, and thick root: it is largest at the top or head, and from thence, gradually grows smaller. Sometimes it is single and undivided to the bottom; but more frequently it is divided into two or more parts. From this root arise a number of very long leaves, broadest in the middle, narrow towards the base, and obtusely pointed at the end: they are a foot or more in length, and about five inches in breadth; of a dusky and disagreeable green color, and of a very fetid smell. The female mandrake perfectly resembles the other in its growth; but the leaves are longer and narrower, and of a darker color, as are also the seeds and roots. It grows naturally in Spain, Portugal, Italy, and the Levant. These three last species are propagated by seeds, and placed in stoves. This plant has been recommended as a cure for barrenness. Its fresh root is a violent purge, the dose being from ten to twenty grains in substance, and from half a dram to a dram in infusion. It has been found to do service in hysteric complaints; but must be used with great caution, otherwise it will bring on convulsions, and other mischievous symptoms. It has also a narcotic quality. At present only the

fresh leaves are sometimes used in anodyne and emollient cataplasms and fomentations. It used to be an ingredient in one of the old officinal unguents; but both that and the plant itself are now rejected from our pharmacopœias. It still, however, retains a place in the foreign ones, and may perhaps be considered as deserving farther attention. No modern botanist will admit the human figure ordinarily ascribed to its roots, especially since the discovery of the artifice of charlatans in fashioning it, to surprise the credulity of the people. Moses informs us, (Gen. xxx. 14.) that Reuben, being in the field, happened to find mandrakes, which he brought home to his mother Leah. Rachel wished for them, and obtained them from Leah, upon a certain condition. The term *דודאים* *dudaim*, here made use of by Moses, is one of those words of which the Jews at this day do not understand the true signification. Some translate it violets, others lilies or jessamine. Junius calls it agreeable flowers; Codurquus makes it truffle, or mushroom; but Calmet will have it to be the citron.

ATROPIY. From *α*, privative, and *τροφή*, I nourish. Want of nourishment; a disorder, in which what is taken at the mouth, cannot contribute to the support of the body.

Pining atrophy,

Marasmus, and wide-wasting pestilence. *Milton.*

The mouths of the lacteals may be shut up by a viscid mucus; in which case the chyle passeth by stool, and the person falleth into an *atrophy*.

Arbutnoot on Aliments.

The shaking head, and the contracted limb;
And lingering *atrophy*, and hoary age. *Jugo.*

ATROPHY. See **MEDICINE**, Index.

ATROPOS, in heathen mythology, the name of the third of the Parcae, or Fates. Her business was to cut the thread of life.

ATTACH, } Fr. *attacher*, to fasten by

ATTACHMENT, } means of some tie. To bind both literally and metaphorically.

Fitzons the guards, which on his state did wait,
Attach'd that traitor false, and bound him strait.

Spenser.

The Tower was chosen; that if Clifford should
Excuse great ones, they might (without suspicion or
noise) be presently *attached*. *Bacon's Henry VII.*

Bohemia greets you;

Desires you to *attach* his son, who has
His dignity and duty both cast off.

Shakspeare.

Attach thee firmly to the virtuous deeds

And offices of life: to life itself,

With all its vain and transient joys, sit loose.

Mallet.

It must be confessed a happy *attachment*, which
can reconcile the Laplander to his freezing snows,
and the African to his scorching sun. *Cumberland.*

A sensible mind cannot do violence even to a local
attachment without much pain. *Coeper's Letters.*

ATTACHAMENTA BONORUM, in ancient law books, denotes a distress taken upon the goods or chattels of any person sued for a personal estate, or debt, by the legal attachiators, as a security to answer the action.

ATTACHMENT, in the law of England, implies the taking or apprehending a person by virtue of a writ or precept. It is distinguished from an arrest, by proceeding out of a higher court, by precept or writ; whereas, the latter

proceeds out of an inferior court, by precept only. An arrest lies only on the body of a man; whereas, an attachment lies often on the goods only, and sometimes on the body and goods.

ATTACHMENT BY WRIT differs from distress, in not extending to lands, as the latter does; nor does a distress touch the body as an attachment does.

ATTACHMENT, FOREIGN, is an attachment of money or goods found within a liberty or city, to satisfy some creditor within such liberty or city. By the custom of London, and several other places, a man can attach money or goods in the hands of a stranger, to satisfy himself. If a claim be exhibited in the mayor's or the sheriff's court (the proceeding in the former being the most advantageous) against A, and the process be returned nihil, and thereupon the plaintiff suggests that another person within London is indebted to A, the debtor shall be warned (whence he is called the garnishee), and if he does not deny himself to be indebted to A, the debt shall be attached in his hands. But nothing is attachable, but for a certain and due debt; though by the custom of London, money may be attached before due, as a debt, but not levied before due. Sid. 327. 1 Nels. Abr. 282, 283.

ATTACHMENT OF PRIVILEGE is, by virtue of a man's privilege, to call another to that court whereto he himself belongs, and in respect whereof he is privileged to answer some action.

ATTACHMENT OF THE FOREST, is one of the four courts held in the king's forests. The lowest court is called the court of attachment, or woodmote court; the second is the court of regard, or survey of dogs; the third is that of swainmote, the highest, the Justice in eyre's seat. This attachment is by three means: by goods and chattels, by body, pledges, and mainprize; or by body only. This court is held every forty days throughout the year; whence it is also denominated forty days' court.

ATTACHMENT OUT OF THE CHANCERY, is obtained upon an affidavit made, that the defendant was served with a subpoena, and made no appearance; or it issues upon not performing some order or decree. Upon the return of this attachment by the sheriff, quod non est inventus in balliva sua, another attachment, with a proclamation, issues; and if he still refuses to appear, a commission of rebellion.

ATTACK, *v. & n.* Fr. *attaquer*; from *attacher*, to come into close contact with hostile intentions; to be the aggressor, to offend.

Satan who that day

Prodigious power had shown, and met in arms

No equal ranging through the dire *attack*

Of fighting Seraphim, confus'd at length

Saw where the sword of Michael smote. *Milton.*

An indiscreet man is more hurtful than an ill-natured one, for as the latter will only *attack* his enemies and those he wishes ill to; the other injures indifferently both friends and foes. *Addison.*

Hector opposes; and continues the *attack*; in which Sarpedon makes the first breach in the wall.

Popc. Iliad.

ATTACOTTI, an ancient people of Britain, mentioned by Ammianus Marcellinus, and St.

Jerome, as well as in the *Notitia Imperii*. They are represented as allies of the Scots and Picts, and were, therefore, probably their neighbours; though their precise situation has not been determined by antiquaries.

ATTAGEN, *arrayax*, or *arrayax*; in ornithology, the same with our gor-cock, moor-cock, or red game.

ATTAIN',
ATTAIN'ABLE,
ATTAIN'ABLENESS,
ATTAIN'MENT.

Lat. *attineo*; from *ad*, and *teneo*, to hold. To reach as the object of pursuit or effort, to realize

one's desire, to procure.

Crowns and diadems, the most splendid terrene *attains*, are akin to that; which, to-day is in the field, and to-morrow is cut down. *Glanville's Sceptis.*

He wilfully neglects, the obtaining unspeakable good; which, he is persuaded is certain and *attainable*.

Tillotson.

Persons become often enamoured of outward beauty, without any particular knowledge of its possessor, or its *attainableness* by them. *Cheyne.*

So pleas'd at first the tow'ring Alps we try,
 Mount o'er the vales, and seem to tread the sky;
 The eternal snows appear already past,
 And the first clouds and mountains seem the last:
 But those *attained*, we tremble to survey
 The growing labour of the lengthened way,
 The increasing prospect tires our wond'ring eyes,
 Hills peep o'er hills, and Alps on Alps arise.

Pope's Essay on Criticism.

Among nations, as well as individuals, the powers of imagination *attain* some degree of vigour before the intellectual faculties are much exercised in speculative or abstract disquisition. *Robertson.*

ATTAINDER, in law, is the immediate consequence, when sentence of death, the highest judgment in our laws, is pronounced. For when it is now clear beyond all dispute, that the criminal is no longer fit to live upon the earth, but is to be exterminated as a monster and a bane to human society, the law sets a note of infamy upon him, puts him out of its protection, and takes no farther care of him than barely to see him executed. He is then called *attaint*, *attinctus*, stained, or blackened. He is no longer of any credit or reputation; he cannot be a witness in any court; neither is he capable of performing the functions of another man: for, by an anticipation of his punishment, he is already dead in law. This is after judgment; for there is a great difference between a man convicted and *attainted*; though they are frequently confounded together. After conviction only, a man is liable to none of these disabilities; for there is still in contemplation of law a possibility of his innocence. Something may be offered in arrest of judgment: the indictment may be erroneous, which will render his guilt uncertain, and thereupon the conviction may be quashed: he may obtain a pardon, or be allowed the benefit of clergy; both which suppose some latent sparks of merit, which plead in extenuation of his fault. But, when judgment is pronounced, both law and fact conspire to prove him completely guilty; and there is not the remotest possibility left of any thing to be said in his favor. Upon judgment, therefore, of death, the *attainder* of a criminal commences: or upon such circumstances as are equivalent to judgment of outlawry on

a capital crime, pronounced for absconding from justices which tacitly confesses the guilt: and therefore, upon judgment, either of outlawry, or of death, for treason or felony, a man is said to be *attainted*. A person *attainted* of high treason, forfeits all his lands, tenements, and hereditaments; his blood is corrupted, and he and his posterity rendered base. See **CORRUPTION**, **FORFEITURE**, &c. *Attainders* may be reversed or falsified, (i. e. proved to be false) by writ of error, or by plea. If by writ of error, it must be by the king's leave, &c. and, when by plea, it may be by denying the treason, pleading a pardon by act of parliament, &c. Persons may be *attainted* by act of parliament. Acts of *attainder* of criminals have been passed in several reigns, on the discovery of plots and rebellions, from the reign of king Charles II. when an act was made for the *attainder* of several persons, guilty of the murder of king Charles I. Among acts of this nature, that for *attainting* Sir John Fenwick, for conspiring against king William, is the most remarkable; it being made to *attaint* and convict him of high treason, on the oath of one witness, just after a law had been enacted, 'That no person should be tried or *attainted* of high treason, where corruption of blood is incurred, but by the oath of two lawful witnesses, unless the party confess, stand mute, &c.' Stat. 7 and 8 W. III. cap. 3. But he was indicted of treason, on the oaths of two witnesses, though but only one could be produced against him on his trial. By the VIIth Ann. chap. 21, all corruption of blood, and the forfeiture for ever of a traitor's estate of inheritance, were to have ceased on the death of the then Pretender; but the legislative policy or panic of the reign of George II. caused a further extension of these vindictive principles of law, to the time of the death of the Pretender's sons. And, by an act of the 39th of the late king, the provisions of the statutes of Anne and of George II. for the future abrogation of these hard consequences of *attainder*, were repealed, and the law stood in its original severity. But by an act, introduced by Sir Samuel Romilly, in the 54th year of his late Majesty's reign, corruption of blood, and forfeiture beyond the term of the offender's own life were abolished, except in cases of treason, petty treason, and murder; thus, in part, realising the hope expressed by Mr. Justice Blackstone (Comm. b. iv. c. 29), 'That as every other oppressive mark of feudal tenure is happily worn away, corruption of blood, with all its connected consequences, not only of present escheat, but of future incapacities of inheritance, even to the twentieth generation, may in process of time be abolished by act of Parliament.'

ATTAINT', *v. n.* & *adj.* } Old Fr. *attaindre*;
ATTAIN'DER, } from *tangere*, to
ATTAIN'TURE, } touch, says Min-
ATTAIN'MENT. } shen, because he
 who is *attainted* is touched, caught, or taken: or, from *tingere*, to stain, which is more probable. To stain, to impute charge, or accuse.

Were it not an endless trouble, that no traitor or felon should be *attainted*, but a parliament must be called? *Spenser.*

I must offend, before I be *attainted*. *Shakespeare.*

His warlike shield

Was all of diamond, perfect, pure, and clean;
For, so exceeding shone his glistening ray,
That Phœbus' golden face it did attain;
As, when a cloud his beams doth overlay.

Spenser's Faerie Queene.

My tender youth was never yet attain

With any passion of inflaming love. *Shakesp.*

So smooth he daub'd his vice with shew of virtue;
He liv'd, from all attainder of suspect. *Id.*

Hume's knavery will be the duchess's wreck,
And her attainure will be Humphrey's fall. *Id.*

The ends in calling a parliament were chiefly, to have the *attainders* of all his party reversed; and, on the other side, to attain by parliament his enemies.

Bacon.

How would the sons of Troy in arms renown'd,
And Troy's proud dames whose garments sweep the ground,

Attain the lustre of their former name,
Should Hector basely quit the field of fame?

Pope. Homer.

ATTAIN, in the English law, is a writ that lies after judgment against a jury of twelve men, that have given false verdict in any court of record, in an action real and personal, where the debt or damages amount to above forty shillings, stat. 5 and 34 Ed. III. c. 7. It is called attain, because the party that obtains it endeavours thereby to stain or taint the credit of the jury with perjury, by whose verdict he is grieved. The jury who are to try this false verdict must be twenty-four, and are called the grand jury; for the law wills not that the oath of one jury of twelve men should be attained or set aside by an equal number, nor by less indeed than double the former. And he that brings the attain can give no other evidence to the grand jury, than what was originally given to the petit. For, as their verdict is now trying, and the question is, whether or no they did right upon the evidence that appeared to them, the law adjudged it the highest absurdity to produce any subsequent proof upon such trial, and to condemn the prior justification for not believing evidence which they never knew. But those against whom it is brought, are allowed, in the affirmation of the first verdict, to produce new matter: because the petit jury may have formed their verdict upon evidence of their own knowledge, which never appeared in court; and, because very terrible was the judgment which the common law inflicted upon them, if the grand jury found their verdict a false one. The judgment was, 1. That they should lose their *liberam legem*, and become for ever infamous. 2. That they should forfeit all their goods and chattels. 3. That their lands and tenements should be seized to the king. 4. That their wives and children should be thrown out of doors. 5. That their houses should be rased. 6. That their trees should be rooted up. 7. That their meadows should be ploughed. 8. That their bodies should be cast into jail. 9. That the party should be restored to all that he lost by reason of the unjust verdict. But, as the severity of this punishment had its usual effect, in preventing the law from being executed, therefore, by the statute 11 Hen. VII. c. 24, revived by 23 Hen. VIII.

c. 3, and made perpetual by 13 Eliz. c. 25, it is allowed to be brought after the death of the party, and a more moderate punishment was inflicted upon attainted jurors; viz. perpetual infamy, and if the cause of action were above forty pounds value, a forfeiture of twenty pounds a-piece by the jurors; or, if under forty pounds, then five pounds a-piece; to be divided between the king and the party injured. So that a man may now bring an attain, either upon the statute or at common law, at his election; and in both may reverse the former judgment. But, the practice of setting aside verdicts upon motion, and granting new trials, has so superseded the use of both sorts of attaints, that there is hardly any instance of an attain later than the sixteenth century.

ATTAINT, or ATTEINT, in horsemanship, a hurt in a horse's leg, proceeding either from a blow with another horse's foot, or from an overreach in frosty weather, when a horse, being rough-shod, or having shoes with long calkers, strikes his hinder feet against his fore legs.

ATTALIA, in ancient geography, a sea-port of Pamphylia, seated on a bay of the Mediterranean sea; founded by one of the Attali, kings of Pergamus. In this city Paul and Barnabas preached, about A. D. 49; and it had bishops in the fifth and sixth centuries. It is now called SATTALIA.

ATTALICÆ VESTES, in antiquity, garments made of a kind of cloth of gold. They took the denomination from Attalus, surnamed Philometer, a wealthy king of Pergamus, who was the first, according to Pliny, who caused gold to be woven into cloth.

ATELABUS, in zoology, a genus of insects belonging to the order of coleoptera, or the beetle kind. It has four wings, of which the superior are crustaceous, and serve as a sheath or cover to the inferior, which are membranous. The head tapers behind, and is inclined; the feelers turn thicker towards the apex. The species are thirteen. 1. *A. apiarus* is bluish, with red elytra, and three black belts. It is a native of Germany. 2. *A. avellana* is black, with the breast, feet, and elytra red. 3. *A. betula* has springy legs, and the whole body is of a dark red. It frequents the leaves of the birch. 4. *A. buprestoides* is of a dark color, with a globular breast, and nervous elytra. It is a native of Europe. 5. *A. ceramoides*, is of a blackish red color, and the elytra is furrowed. It frequents the spongy boletus, a species of mushroom. 6. *A. coryli* is black, with red elytra, or crustaceous wings. 7. *A. curculionoides* is black, with red elytra and breast. These two last species, and the *avellana*, frequent the leaves of the hazel and filbert-nut trees. 8. *A. formicarius* is black, with red elytra, and a double white belt towards the base. It is a native of Europe. 9. *A. melanurus* is black, with testaceous elytra, black at the apex. It is a native of Sweden. 10. *A. mollis* is hairy and yellowish, with pale elytra, and three belts. It is a native of Europe. 11. *A. pennsylvanicus* is black, with red elytra, a black belt round the middle, and another towards the apex of the elytra. It is a native of Philadelphia. 12. *A. sipyllus* is green, with a hairy breast, and a double yellow belt upon the

elytra. 13. *A. Surinamensis* has a double indentation, or two teeth, in the top of the elytra.

ATTEMPER, v. & adj. } Lat. of the middle ages, *attempero*.
ATTEMPERATE, }
ATTEMPERANCE, } Lat. *temperare*, to
ATTEMPERLY. } abate, the predominant qualities of a thing. To moderate, to accommodate.

A man should love his wyf by discretien, patiently and *attemprely*, and than is she as though it were his sister. *Chaucer. The Persones Tale, v. ii. p. 363.*

The joyous birds shrouded in cheerful shade,
 Their notes unto the voice *attempered* sweet,
 The angel-call, soft trembling voices made,
 To the instruments' divine response meet.

Spenser.

A monarchy, where is no nobility at all, is ever a pure and absolute tyranny, as that of the Turks; for nobility *attempers* sovereignty, and draws the eyes of the people somewhat aside from the line royal: but for democracies they need not. *Bacon's Essays.*

Phemius! let arts of gods and heroes old,
Attemper'd to the lyre, your voice employ. *Pope.*

Hope must be proportioned and *attemperate* to the promise, if it exceed that temper and proportion, it becomes a tumour and tympany of hope,

Hammond's Pract. Catechism.

Attemper'd suns arise,
 Sweet-beam'd, and shedding oft thro' lucid clouds
 A pleasing calm. *Thomson.*

In the midst a form divine!

Her eye proclaims her of the Briton line;
 Her lion-port, her awe-commanding face,
Attemper'd sweet to virgin-grace.

Gray's Bard.

ATTEMPT, v. & n. } Fr. *attenter*; from
ATTEMPTER, } *tenter*, which is from
ATTEMPTABLE, } the Latin *tentare*, to
ATTENTATE. } try. To make experiment; to make an effort to accomplish an object; to undertake.

The gentleman, vouching his to be more fair, virtuous, wise, and less *attemptable*, than the rarest of our ladies. *Shakespeare.*

LUCIO. Our doubts are traitors,
 And make us lose the good we oft might win
 By fearing to attempt. *Id. Measure for Measure.*
 Alack! I am afraid, they have awak'd,
 And 'tis not done; th' attempt, and not the deed,
 Confounds us. *Id. Macbeth.*

He flatt'ring his displeasure,

Tript me behind; got praises of the king,
 For him *attempting*, who was self-subdu'd. *Id.*
 He would have cry'd; but, hoping that he dreamt,
 Amazement tied his tongue, and stopp'd th' attempt.

Dryden.

If we be always prepared to receive an enemy; we shall long live in peace and quietness, without any attempts upon us. *Bacon.*

I have nevertheless *attempted* to send unto you, for the renewing of brotherhood and friendship.

1 Mac. xii. 17.

Who, in all things wise and just,
 Hinder'd not Satan to attempt the mind
 Of man, with strength entire and free-will arm'd.

Milton.

The Son of God, with godlike force endu'd,
 Against th' *attempter* of thy Father's throne. *Id.*
 You are no factors, for glory or treasure; but disinterested *attempters*, for the universal good.

Glanville's Scepais.

Fools only make *attempts* beyond their will,
 A wise man's pow'r's the limit of his will.

Congreve.

He that would succeed in a project of gain, must never attempt to gain too much; and upon proper occasions, must know how to lose.

Hawkesworth's Telemachus.

A lion of Numidia, that hunger has made more furious, rushes among the flocks; he kills and tears to pieces without resistance; and the shepherds, instead of *attempting* to defend their sheep, fly with terror and trepidation to preserve themselves. *Id.*

ATTEND,
ATTEND'ANCE,
ATTEND'ANT, n. & adj.
ATTEND'ER,
ATTENT,
ATTENT'ION,
ATTENT'IVE,
ATTENT'IVELY,
ATTENT'IVENESS.

Lat. *attendo*; from *ad* and *tendo*, to stretch to or towards. To direct the mind to; to look to what one is about; to have the faculties engaged or the affair in hand; to wait.

The fifth had charge, sick persons to attend;
 And comfort those, in point of death which lay.

Spenser.

He that goeth about to persuade a multitude, that they are not so well governed as they ought to be, shall never want *attentive* and favourable hearers.

Hooker's Ec. Polity.

I will be returned forthwith: dismiss your *attendant* there; look it be done! *Shakespeare. Othello.*

England is so idly king'd,

Her sceptre so fantastically borne;

That fear *attends* her not. *Id.*

I'm never merry, when I hear sweet musick:

The reason is, your spirits are *attentive*.

Id. Merchant of Venice.

My pray'rs and wishes always shall attend

The friends of Rome. *Addison's Catc.*

A vehement, burning, fixed, pungent pain in the stomach, *attended* with a fever. *Arbuthnot on Dict.*

I saw most of them *attentive* to three Sirens, distinguished by the names of Sloth, Ignorance, and Pleasure. *Tatler.*

The diligent pilot, in a dangerous tempest, doth not *attend* the unskilful words of a passenger. *Sidney.*

The gypsies were there,

Like lords to appear;

With such their *attenders*,

As you thought offenders. *Ben Jonson.*

Now mine eyes shall be open; and mine ears *attent* unto the prayer, that is made in this place.

2 Chron. vii. 15.

What can then be less in me, than desire

To see thee, and approach thee, whom I know

Declar'd the Son of God; to hear *attent*

Thy wisdom, and behold thy godlike deeds?

Milton.

Other suns perhaps,

With their *attendant* moons, thou wilt descry,

Communicating male and female light.

Id. Paradise Lost.

Unknown sins have their guilt and shame, and are justly *attended* with known punishments.

Hall's Contemplations.

We all are never weary of receiving, soon weary of *attending*.

At length her lord descends upon the plain

In pomp *attended* with a numerous train. *Dryden.*

Hush'd winds the topmost branches scarcely bend,
 As if thy tuneful song they did *attend*. *Id.*

Plant anemones after the first rains, if you will have flowers very forward: but it is surer to *attend* till October. *Evelyn.*

With these four more of lesser fame,
 And humble rank *attendant* came ;
 Hypocrisy with smiling grace,
 And Impudence with brazen face,
 Contentment bold with iron lungs,
 And Slander with her hundred tongues. *Moore.*

He [Termsiris priest of Apollo] related past events with such force of expression that they seemed to be present; and with such comprehensive brevity, that *attention* was not wearied; and he foresaw the future by a sagacity that discovered the true characters and dispositions of mankind, and the events which they would produce. *Hawkesworth's Telemachus.*

ATTENTION has also been defined, a due application of the ear, or the eye, as well as of the mind, to any thing said or done, in order to acquire a knowledge thereof.

Attention of mind is not properly an act of the understanding, but rather of the will, by which it calls the understanding from the consideration of other objects, and directs it to the thing in hand. Nevertheless, our attention is not always voluntary; an interesting object seizes and fixes it beyond the power of control. Attention, in respect of hearing, is the stretching or straining of the membrana tympani, so as to make it more susceptible of sounds, and better prepared to catch even a feeble agitation of the air: or, it is the adjusting the tension of that membrane to the degree of loudness or lowness of the sound to which we are attentive. According to the degree of attention, objects make a stronger or weaker impression. Bacon, in his Natural History, observes, that 'Sounds are meliorated by the intension of the sense, where the common sense is collected most to the particular sense of hearing, and the sight suspended. Therefore sounds are sweeter, as well as greater, in the night than in the day; and I suppose they are sweeter to blind men than to others; and it is manifest, that between sleeping and waking, when all the senses are suspended, music is far sweeter than when one is fully waking.' Attention is requisite even to the simple act of seeing: the eye can take in a considerable field at one look; but no object in the field is seen distinctly but that singly which fixes the attention: in a profound reverie that totally occupies the attention, we scarce see what is directly before us. In a train of perceptions, no particular object makes such a figure as it would do singly and apart: for, when the attention is divided among many objects, no particular object is entitled to a large share. Hence, the stillness of night contributes to terror, there being nothing to divert the attention. In matters of slight importance, attention is mostly directed by the will; and, for that reason, it is our own fault if trifling objects make any deep impression. Had we power equally to withhold our attention from matters of importance, we might be proof against any deep impression. But our power fails us here; and, while our attention is thus forcibly attached to one object, others will solicit it in vain.

ATTENUANTS, or ATTENUATING MEDICINES, are such as subtilise and break the humors into finer parts; and thus dispose them for motion, circulation, excretion, &c. They are of extensive use in physic, and come under different denominations, according to the differ-

ent effects they produce. Thus, when tenacious and viscid juices not only stagnate in the cavities of the vessels, but obstruct the minute ducts of the viscera and emunctories, these medicines, by their inciding and attenuating qualities, discharge the humors, and remove the obstructions; for which reason they are not improperly called aperients. Attenuants produce so great a variety of effects, that it is proper we should be well acquainted with their several kinds, as appropriated to the several disorders, and know which will prove most serviceable in each. According to Hoffman, the dissolving and attenuating of viscid crudities in the stomach and primæ viæ, is well answered by the roots of arum, acorus, pepper, ginger, and the like; as also by sal ammoniac, vitriolated tartar, the fixed alkaline salts, and the simple or dulcified spirit of salt. When crude and unconcocted humors are to be evacuated by stool, this intention is very well answered by the neutral salts, as the salts of the purging waters, and the sal polycrestum, with a sufficient quantity of a watery vehicle. When viscid humors, occasioning disorders of the breast, are to be attenuated and expectorated, the intention is most effectually answered by elecampane and orrice roots; and by gum ammoniacum, myrrh, or benjamin, and balsam of Peru; or by regenerated tartar, oxymel of squills, a solution of crabs' eyes in distilled vinegar, and the syrup of tobacco, and the like. When the mass of blood is tainted by thick and tenacious sordes, and the emunctories are by that means obstructed, and the humors contaminated by a saline sulphureous and scorbutic dyscrasy, the most efficacious of the attenuants are the horse-radish, scurvy-grass, water and garden cresses, mustard, gum ammoniac, benjamin, myrrh, the oil of fixed nitre, oil of tartar per deliquium, solutions of nitre, spirit of sal ammoniac, salt of wormwood with lemon juice, and the salts of the medicinal waters. When grumous or coagulated blood, occasioned by contusions or blows, is to be attenuated and again dissolved, the intention is sure to be answered by the roots of Solomon's Seal, vinegar, and crabs' eyes, the regenerated tartar, and nitre prepared with antimony. And in cases where the lymph has acquired a preternatural thickness and viscidness, especially if from a venereal taint, the curative intention is most effectually answered by guaicum, the acrid tincture of antimony, calomel, Æthiop's mineral, and the like; which, when skilfully used, are of singular efficacy in dissolving and attenuating the viscid juices impacted in the glands of the liver.

ATTENUATE, *v. & n.* } Lat. *attenuo*, to
 ATTENUATION } thin; from *ad* and
tenuis, to thin; from *tendo*, to stretch. To draw out in length or superficial extent; to lessen or thin; to dilate.

Chiming with a hammer upon the outside of a bell, the sound will be according to the inward concave of the bell; whereas the elision, or *attenuation* of the air, can be only between the hammer and the outside of the bell. *Bacon.*

Vivification ever consisteth in spirits *attenuate*, which the cold doth congeal and coagulate. *Id.*

The ingredients are digested and *attenuated* by heat; they are stirred and constantly agitated by winds.

Arbutinot,

Of such concernment too is drink and food,
T' encrassate or attenuate the blood.

Dryden's Translation of Lucretius.

ATTENUATION is defined more generally by Chauvin, the dividing or separating of the minute parts of any body, which before, by their mutual nexus or implication, formed a more continuous mass. Accordingly, among alchemists we sometimes find the word used for pulverisation, or the act of reducing a body into an impalpable powder, by grinding, pounding, or the like.

ATTENUATION, in medicine, the lessening the power or quantity of the morbid matter.

ATTERBURY (Bishop Francis), son of Dr. Lewis Atterbury, was born at Milton in Buckinghamshire, in 1662; educated at Westminster, and thence elected to Christ-Church, in Oxford, where he soon distinguished himself by his genius. In 1687 he was made M.A., when he exerted himself in the controversy with the papists, vindicated Luther in the strongest manner, and displayed an uncommon fund of learning, enlivened with great vivacity. In 1690 he married Miss Osborn, a lady of great beauty, but moderate fortune. About 1690 he took orders, and in 1691 was elected lecturer of St. Bride's church in London, and preacher at Bridewell chapel. He was soon after appointed chaplain to king William and queen Mary. The share he took in the controversy against Bentley, (about the authenticity of Phalaris's Epistles) is now clearly ascertained. In 1700 a still larger field of activity opened, in which Atterbury was engaged four years with Dr. Wake (afterwards archbishop of Canterbury), and others, concerning 'the Rights, Powers, and Privileges of Convocations;' in which he displayed so much learning and zeal for the interests of his order, that the lower house of Convocation returned him their thanks, and the university of Oxford complimented him with the degree of D.D. January 29, 1700, he was installed archdeacon of Totness. The same year he was engaged, with some other learned divines, in revising an intended edition of the Greek Testament, with Greek Scholia, collected chiefly from the fathers, by Mr. Archdeacon Gregory. At this period he was popular, as preacher at the Rolls chapel; an office which had been conferred on him by Sir John Trevor, in 1698, when he resigned Bridewell. Upon the accession of queen Anne, in 1702, Dr. Atterbury was appointed one of her chaplains; and in October 1704, was advanced to the deanery of Carlisle. About two years after this, he was engaged in a dispute with Mr. Hoadly, concerning the advantages of virtue, with regard to the present life; occasioned by his sermon, preached August 30, 1706, at the funeral of Mr. Thomas Bennet, a bookseller. In 1707 Sir Jonathan Trelawney, bishop of Exeter, appointed him one of the canons residentiaries of that church. In 1709 he was engaged in a fresh dispute with Mr. Hoadly, concerning 'Passive Obedience;' occasioned by his Latin sermon, entitled 'Concio ad Clerum Londinensem, habita in Ecclesia S. Elphegi.' In 1710 came on the famous trial of Dr. Sacheverell, whose remarkable speech on

that occasion was generally supposed to have been drawn up by our author, in conjunction with Dr. Smalridge and Dr. Freind. The same year Dr. Atterbury was unanimously chosen prolocutor of the lower house of Convocation, and had the chief management of affairs in that house. May 11, 1711, he was appointed by the convocation one of the committee for comparing Mr. Whiston's doctrines with those of the church of England; and in June following, he had the chief hand in drawing up 'A Representation of the present State of Religion.' In 1712 he was made dean of Christ Church, notwithstanding the strong interest and warm applications of several great men in behalf of his competitor, Dr. Smalridge. In the beginning of June, 1713, the queen advanced him to the bishopric of Rochester, with the deanery of Westminster in commendam. He was confirmed July 4, and consecrated at Lambeth next day. The death of the queen, in 1714, put an end to all farther hopes of advancement; for the new king treated him with great coolness, doubtless aware of either the report or the fact of his offer, on the death of Anne, to proclaim the Pretender in full canonicals, if allowed a sufficient guard. This dislike operated like oil on the inflammable mind of Atterbury, who not only refused to sign the loyal declaration of the bishops in the rebellion of 1715, but suspended a clergyman for lending his church for the performance of divine service to the Dutch troops brought over to serve against the rebels. Not content with a constitutional opposition, he entered into a correspondence with the Pretender's party, in favor of the dispossessed family; for which offence he was apprehended in August 1722, and committed to the Tower; and in the March following a bill was brought into the House of Commons, for the infliction of pains and penalties. This measure, which on constitutional grounds can never be defended, and which indeed was supported chiefly on the urgency of the particular time and case, met with considerable opposition in the Lords, and was resisted with great firmness and eloquence by the bishop, who maintained his innocence with his usual acuteness and dexterity. His guilt however has been tolerably well proved by documents since published; and nothing more is necessary to warrant a confirmed moral distaste to his character, than the contemplation of such a scene of smooth dissimulation and hypocrisy. By this bill the bishop was deprived and outlawed, and no British subject was permitted to visit him abroad, without the king's sign manual; which however was not refused to his relatives.

On the 27th, this prelate having that day taken leave of his friends, who, from the time of passing the bill against him to the day of his departure, had free access to him in the Tower, embarked on board the Aldborough man of war, and landed the Friday following at Calais. When he went on shore, having been informed that lord Bolingbroke, who, after the rising of the parliament, had received the king's pardon, was arrived at the same place on his return to England, he said, with an air of pleasantry, 'Then I am exchanged!' When bishop Atterbury first

entered upon his banishment, Brussels was the place destined for his residence; but he was compelled to leave that place, and retire to Paris. He next changed his abode for Montpellier, in 1728; and, after residing there about two years, returned to Paris, where he died February 15, 1731. As a composer of sermons, Dr. Aterbury still retains the highest reputation; his periods are easy and elegant, his style flowing and beautiful; but as a critic or disputant, he is rather dexterous than accurate, and rather popular than profound.

ATTERBURY (Dr. Lewis), eldest son of the Dr. and brother to the bishop, was born at Caldecot, in Bucks, in 1656; educated at Westminster, and sent to Oxford in 1674. In 1679 he entered into orders, and commenced A. M. in 1680; in 1683 he was made chaplain to Sir W. Pritchard; in 1684 rector of Symel; in 1687, L.L.D. and in 1691 lecturer of St. Mary-at-Hill, London. In 1695 he was elected preacher at Highgate, and was appointed one of the six preaching chaplains to the princess Anne of Denmark, at Whitehall and St James's; in which place he was continued after she became queen, and during part of the reign of George I. In 1707 the queen appointed him rector of Shepperton, and in March 1709, the bishop of London collated him to the rectory of Hornsey. He died at Bath, of a paralytic disorder, in 1731. He published, during his life, 2 vols. of Sermons, and four occasional ones, besides other pieces. He was remarkably benevolent and charitable. While he resided at Highgate, observing that the poor in that neighbourhood were much at a loss for medical advice, he studied physic, and practised it gratis among them: he also gave £10 annually to a teacher, to instruct young girls at Newport Pagnel, and burdened his estate with this annual payment for ever. He left 200 volumes of pamphlets to the library of Christ Church, Oxford.

ATTES, in fabulous history, a son of Calaus of Phrygia, who was born impotent. The worship of Cybele was introduced among the Lydians by him, after which he was highly honored by the goddess. His success awakened a jealousy in Jupiter, and he sent a wild boar to lay waste the country, that Attes might be destroyed.

ATTEST, *v. & n.* } Lat. *attestor*; *ad* and
ATTESTER, } *testor*, to call to witness.
ATTESTATION. } To corroborate or strengthen by witness, i. e. by one who has had the evidence of one or more of the senses.

With the voice divine

Nigh thunderstruck, th' exalted man, to whom

Such high *attest* was giv'n, a while survey'd

With wonder.

Paradise Regained.

Many particular facts are recorded in holy writ, attested by particular pagan authors.

Addison.

We may derive a probability, from the attestation of wise and honest men, by word or writing; or the concurring witness of multitudes, who have seen and known, what they relate.

Watts.

Prodivine actions may as well be done

By weaver's issue, as by prince's son.

This arch-attestor of the publick good,

By that one deed embles all his blood.

Dryden's Absalom and Achitophel.

ATTIUS, a daughter of Cranaus, the second king of Athens. According to Apollodorus she gave her name to Attica.

ATTIC, any thing relating to Attica, or Athens, or any thing peculiarly elegant or excellent.

ATTIC BASE, a peculiar kind of base used by the ancient architects in the Ionic order; and by Palladio, and some others, in the Doric.

ATTIC ORDER, or **ATTICS**, in architecture, a kind of order, after the manner of a pedestal, raised upon another larger order, by way of crowning, or to finish the building. See **ARCHITECTURE**, Index.

ATTIC SALT, a delicate, poignant kind of wit, peculiar to the ancient Athenians. The term is applied to any similar piece of humor in modern writings.

ATTIC STORY, in architecture, a story in the upper part of a house, where the windows are usually square.

ATTIC WITNESS, a witness incapable of corruption.

ATTICA, an ancient state of Greece, situated along the north coast of the gulph of Saron, bounded on the west by Megara, mount Cithæron, and part of Bœotia; on the north by the gulph of Euripus (now called Stretto di Negroponte, or the Strait of Negropont), and the rest of Bœotia; and on the east by the Euripus. It extended in length from north-west to south-east, about sixty miles; its breadth from north to south was fifty-six, decreasing as it approached the sea. The soil of this country was naturally barren and craggy, though by the industry of its inhabitants it produced all the necessaries of life. On this account, Attica was less exposed to invasions than other more fertile countries; and hence, it preserved its ancient inhabitants, beyond all the other kingdoms in its neighbourhood; so that they were reputed to be the spontaneous productions of the soil; and as a badge of this, Thucydides tells us, they wore golden grasshoppers in their hair.

The principal mountains of Attica were Laurium, celebrated for its silver mines, and situated near the Sunian promontory; Pentelicus, famous for its quarries of white marble; and Hymettus, near Athens, remarkable for the abundance and fineness of its honey. Other mountains mentioned in history, are Ægialeus, Brilessus, Icarium, Lycabettus, and Parnethus. Its principal rivers were the Cephissus, Eridanus, and Ilissus. Although the mountainous character of the country rendered it unpromising and sterile for grain generally, barley was produced in abundance; and Aristotle observes that the fruits of Attica had a peculiar sweetness. The culture of the olive tree was protected by law, and a fine of 200 drachmæ (upwards of £8 sterling) was paid by any person who rooted up on his grounds more than two trees in a year, unless for the service of the gods. The olives called colymbades, considered larger and of richer flavor than any other, retain their name to this day, and were, until the late civil wars, monopolised for the personal use of the grand signior.

The chief cities of Attica were Athens, the capital. See **ATHENS**. Next to it Eleusis, situated on the same gulph, near the coasts of Megara;

and next to that Rhamnus, famed for the temple of Amphiarus, and the statue of the goddess Nemesis, sculptured by Phidias, from a block of Parian marble, which the Persians had brought thither to assist in erecting a trophy of their proposed victory. It was ten cubits high, and was inscribed with the name of his favorite pupil Agoracritus. Nor ought we to omit to mention the town of Marathon, ten miles north-east of Athens, immortalised by the victory gained there by Miltiades over the Persians. On the plain of the battle the Athenians erected small columns, on which the names of those warriors who fell were inscribed. A monument afterwards raised to Miltiades himself, was set apart, a small distance from the rest: in the intervals between these columns were trophies, bearing the arms of the Persians.

Attica was divided into ten tribes, called *φυλαι*; and these again were subdivided into 174 boroughs, or *δημοι*. The inhabitants were of three classes: 1. Citizens, *πολιται*; whose numbers underwent little change from the time of Cecrops, and averaged about 20,000. They had a right, from a certain property, to vote in the general assembly; about 60,000 others were freemen without this privilege. Those who sprung from parents both of whom were Athenian citizens, were considered freeborn, though occasionally the privilege was extended to such as had one parent only of this class. The honor was conferred on foreigners by a vote of the people, ratified at two solemn assemblies; at the second of which it was requisite that 6,000 citizens should be present. But no one, except a free born Athenian, could hold an archonship. 2. Foreigners settled in Attica, and enrolled in the public registers, *μετοικοι*. They were protected by the state; but were not permitted to hold any public office. Each *μετοικος* selected a citizen as his protector, *προστατης*; who stood to him much in the same relation as the Roman patronus did to his clients. They paid an annual tribute to the state of twelve drachmæ (about nine shillings), and in default of payment they were sold as slaves. Their number (males only) in the time of Demetrius of Phalerum, (307 B. C.) was 10,000. 3. Slaves, *δουλοι*, who, when numbered at the same time, amounted to 400,000. The agricultural, mining, and menial labor was performed by them; as well as the greater part of that of the public works, and of private manufactures. The entire population of ancient Attica may be taken at about half a million, or nearly 900 to a square mile; about one-fourth of that of Middlesex. For the political history of this interesting country, including the details of its recent struggles for liberty, see our article GREECE.

ATTICISE, }
 ATTICISM, } Gr. *Αττικίζω*, to speak or
 ATTICK, } write after the Attic dialect.
 ATTICAL. }

There while they acted and overacted, among other young scholars, I was a spectator; they thought themselves gallant men, and I thought them fools; they made sport, and I laughed; they mispronounced, and I misliked; and to make up the *atticism*, they were out, and I hist. *Milton.*

If any will still excuse the tyrant for *atticising* in those circumstances, it is hard to deny them the glory of being the faithfullest of his vassals.

Bentley. Dissertation on Phalaris.

ATTICUS (Titus Pomponius), one of the most remarkable characters of ancient Rome. He managed himself with such address, that he preserved the esteem and affection of all parties. He sent money to the younger Marius, and yet was a favorite with Sylla. He pleased Cæsar without offending Pompey. He sent supplies to Brutus, while he was doing kind offices to Antony. His strict friendship with Cicero did not hinder him from having great intimacy with Hortensius; and in the contests between Antony and Augustus, he preserved the regard of both. The contests at Rome between the parties of Sylla and Marius, however, induced him to retire to Athens, where he gained the affection of the Athenians so much, that the day he left them was a day of mourning. He was very fond of learning, and kept several librarians and readers. He might have obtained the most considerable posts in the republic; but chose rather not to meddle, because in the corruption and faction which then prevailed, he could not discharge them according to the laws. He wrote annals, which Cicero praises, as having been of great use to him. He married his daughter to Agrippa, and died at the age of 77.

ATTICUS (Herodes), a celebrated orator of antiquity, was born at Marathon. His lectures on elocution were heard with such applause, that he was sent for by Titus Antoninus, to instruct Marcus Aurelius, and Lucius Verus. He was honored with the consulship, and other high offices. He generously erected an aqueduct at Troas, of which he had been made governor, and some other public buildings in different places of the empire, equally useful and magnificent. He was particularly liberal as a benefactor to Athens. He died at Marathon, at the age of 76.

ATTICUS, patriarch of Constantinople, was by birth an Armenian, and flourished in the fifth century. In A. D. 406, he condemned John Chrysostom, by which he got possession of the patriarchate; but Pope Innocent I. being offended at his proceedings, excommunicated him. However, when Chrysostom died, he was allowed to retain his seat. He died in 427.

ATTILA, king of the Huns, lived in the fifth century. He was surnamed 'the Scourge of God,' a title which all offensive conquerors have more or less merited, though none but Attila is said to have assumed and gloried in it. He may justly be ranked among the greatest conquerors, for there was scarcely any province in Europe which did not feel the weight of his victorious arms. Attila deduced his descent from the ancient Huns, who had formerly contended with the monarchs of China. His features, according to the observation of a Gothic historian, bore the stamp of his national origin; and the portrait of Attila exhibits the genuine deformity of a modern Calmuck; a large head, a swarthy complexion, small, deep-seated eyes, a hooked nose, a few hairs in the place of a beard, broad shoulders, and a short square

body, of nervous strength, though of a disproportioned form. The haughty demeanor of this tyrant expressed the idea he entertained of his superiority above the rest of mankind; and he had a custom of fiercely rolling his eyes, as if he wished to enjoy the terror which he inspired. Yet this savage hero was not inaccessible to pity; his suppliant enemies might confide in his assurance of peace or pardon; and he was considered by his subjects as a just and indulgent master. He delighted in war; but, after he had ascended the throne in a mature age, his head, rather than his hand, achieved the conquest of the north; and the fame of an adventurous soldier was usefully exchanged for that of a prudent and successful general. The effects of mere personal valor are indeed so inconsiderable, that victory, even among barbarians, depends on the degree of skill, with which the passions of the multitude are guided for the service of a single man. The arts of Attila were skilfully adapted to his age and country. It was natural that the Scythians should adore the god of war; but as they were incapable of forming either an abstract idea, or a corporeal representation of him, they worshipped him under the symbol of an iron scymitar. One of the shepherds of the Huns perceived that a heifer, who was grazing, had wounded herself in the foot; and curiously followed the tract of the blood, till he discovered among the long grass, the point of an ancient sword; which he dug out of the ground, and presented to Attila. That artful prince accepted with pious gratitude this celestial favor; and, as the rightful possessor of the sword of Mars, asserted his divine and indefeasible claim to the dominion of the earth. Thus this favorite of Mars acquired a sacred character, which rendered his conquests easy and permanent; and the barbarian princes confessed, in the language of devotion or flattery, that they could not presume to gaze with a steady eye on the divine majesty of the king of the Huns. His brother Bleda, who reigned over a considerable part of the nation, was compelled to resign his sceptre and his life. Yet even this cruel act was attributed to a supernatural impulse; and the vigor with which Attila wielded the sword of Mars convinced the world that it had been reserved alone for his invincible arm. But the extent of his empire affords the only remaining evidence of the number and importance of his victories; and the Scythian monarch, however ignorant of the value of science and philosophy, might lament that his illiterate subjects were destitute of the art which could perpetuate the memory of his exploits. Attila, indeed, may claim the title of supreme and sole monarch of the barbarians. He alone, among the conquerors of ancient and modern times, united the two mighty kingdoms of Germany and Scythia. Thuringia, which stretched beyond its actual limits as far as the Danube, was in the number of his provinces: he interposed, with the weight of a powerful neighbour, in the domestic affairs of the Franks; and one of his lieutenants chastised, and almost exterminated, the Burgundians of the Rhine. He subdued the islands of the ocean, the kingdoms of Scandinavia, encompassed and divided by the

waters of the Baltic; and the Huns derived a tribute of furs from that northern region, which has been protected from all other conquerors by the severity of the climate, and the courage of the natives. Towards the east, it is difficult to circumscribe the dominion of Attila over the Scythian deserts; yet we may be assured that he reigned on the banks of the Volga; that he was dreaded, not only as a warrior, but as a magician; that he vanquished the khan of the formidable Geougen; and that he sent ambassadors to negotiate an equal alliance with the empire of China. In the proud review of the nations who acknowledged the sovereignty of Attila, and who never entertained during his lifetime the thought of a revolt, the Gepidæ and the Ostrogoths were distinguished by their numbers, their bravery, and the personal merit of their chiefs. Ardaric, king of the Gepidæ, was the faithful and sagacious counsellor of the monarch; who esteemed his intrepid genius, whilst he loved the mild and discreet virtues of the noble Walamir, king of the Ostrogoths. The crowd of vulgar kings, who served under the standard of Attila, were ranged in the submissive order of guards and domestics round the person of their masters. They watched his nod; they trembled at his frown; and at the first signal of his will they executed without hesitation his absolute commands. In time of peace the dependent princes with their national troops attended the royal camp in regular succession; but when Attila collected his military force he was able to bring into the field an army of five, or according to some, 700,000 barbarians. See HUNS. The circumstances attending Attila's death (about A. D. 453) were remarkable; from the festive throng, which celebrated his nuptials with a beautiful virgin named Ildico, he retired late to bed, oppressed with wine, and during the night a blood-vessel burst and suffocated him. In the morning the bride was found by the bed-side, bewailing his death and her own danger. His body was exposed in the plain, while the Huns marched round it in martial order, singing funeral songs to his praise; and was afterwards enclosed in coffins of gold, silver, and iron, and interred privately in the night. To prevent the violation of his remains, by the discovery of his grave, the slaves who were employed on the occasion were put to death.

ATTILATUS EQUUS, in old law Latin, a horse dressed in his harness, for the plough or cart.

ATTILUS, in ichthyology, a river-fish, of the sturgeon kind, called by some adello, adano, and adeno. It grows to a very large size, and when full grown, casts its scales, and never has any fresh ones, but remains perfectly smooth; in which it differs from the common sturgeon. But it seems not to differ in any essential point from the hussu germanorum. It is an eatable fish, but is greatly inferior in taste to the sturgeon.

ATTINGA, in ichthyology, a species of the diodon.

ATTIR'E, v. & n. } Of uncertain derivation.
ATTIR'ING, } It may be observed, without deciding the question
ATTOUR. } of etymology, that the tiara was an head-dress worn by Phrygian and Persian priests and kings

at sacrifices. Hence the word is found in Greek authors, and is probably derived from the Persic—

Phrygia vestitur bucca tiara. Juvenal.

The high crowned covering for the head, still worn by the natives of Persia, in contradistinction to the low turban of the Turks, is worthy of remark. The word is sometimes applied to the mitres of bishops. The French *attirer*, is to draw to; *attirail*, is the apparatus necessary to an equipage or adorning.

Let it likewise your gentle breast inspire,
With sweet infusion; and put you in mind
Of that proud maid, whom now those leaves *attire*,
Proud Daphne. *Spenser.*

It is no more disgrace to Scripture, to have left things free, to be order'd by the church; than for Nature, to have left it to the wit of man, to devise his own *attire*. *Hooker.*

My Nan shall be the queen of all the fairies;
Finely *attired* in a robe of white.
Shakspeare. Merry Wives of Windsor.
With the linen mitre shall he be *attired*.
Lev. xvi. 4.

After that, the Roman *attire* grew to be in account, and the gown to be in use among them.

Davies on Ireland.

Now the sappy boughs
Attire themselves with blooms. *Philips.*
Whose herbs with milk, whose fields with bread,
Whose flocks supply him with *attire*,
Whose trees in summer yield him shade,
In winter fire. *Pope's Ode on Solitude.*

ATTIRE, in hunting; the attire of a stag, if perfect, consists of bur, pearls, beam, gutters, antler, fur-antler, royal, fur-royal, and crotches; and that of a buck, of the bur, beam, brow-antler, advancer, palm, and spellers.

ATTIRET (John Denis), a French jesuit and painter, was born at Dole, in Franche Comté, in 1702, and died in 1768 at Pekin, whither he had accompanied the mission. He was employed by the emperor Kien Long to paint many battle-pieces, with which he was so much pleased, that he offered him the dignity of a mandarin, and when he declined the honor of the title, he granted him the revenues of the post.

ATTITUDE. Ital. *attitudine*. Supposed to be corrupted from low Latin *aptitudo*, from *apto*, I fit. A term used by the Italians in the art of design, to denote the gesture fitted for the display of grace, beauty, or other quality of form; expressive posture.

Bernini would have taken his opinion, upon the beauty and *attitude* of a figure. *Prior's Ded.*

They were famous originals, that gave rise to statues, with the same air, posture, and *attitudes*.
Addison.

ATTIUM, in ancient geography, a promontory on the north-west of Corsica, now called Punta di Acciuolo.

ATTLEBOROUGH, a town in Norfolk, once the capital of the county, on the road from Thetford to Norwich, about twelve miles from each, and ninety-three from London. It is also called Attlebury. Market, Thursday.

ATTOCK, a river of Asia, which rises in the Tartarian mountains, north of Hindostan, and passing by Cabul, falls into the Indus. By a treaty between Kouli Khan, Shah of Persia, and

the Great Mogul, it was made the boundary between Persia and India.

ATTOCK, Atac, a limit, a town in the province of Lahore, on the east side of the Indus, which is here, in the month of July, from three-fourths to one mile across. Lat. 33° 6' N., long. 71° 15' E. The ancient name of Attock, to this day, is Varanas, or Benares; but it is more generally known by the name of Attock. The fortress was built by Acher, A. D. 1581.

'It is remarkable,' says Mr. Hamilton, 'that the three great invaders of Hindostan, Alexander, Tamerlane, and Nadir Shah, in three distant ages, and with views and talents extremely different, advanced by the same route, with hardly any deviation. Alexander had the merit of discovering the way: after passing the mountains he encamped at Alexandria Paropamisana, on the same site with the modern city of Candahar; and having subdued or conciliated the nations seated on the north west-bank of the Indus, he crossed the river at Taxila, now Attock, the only place where the stream is so tranquil that a bridge can be thrown over it.'

ATTOLLENS, in anatomy, an appellation given to several muscles otherwise called levatores and elevatores.

ATTONITUS MORBUS, **ATTONITUS STUPOR**, an apoplexy; also being planet-struck or blasted.

ATTORN, Fr. *attourner*; *attor-ATTOR'NEY*, v. & n. } *nare*, Du Fresne, to turn
ATTOR'NEYSHIP. } over to, or transfer; to perform service. Ang.-Sax. *tyrnan*, to turn.

As I was then,

Advertising and holy to your business,
Nor changing heart with habit; I am still
Attorned to your service. *Shakspeare.*

But marriage is a matter of more worth,
Than to be dealt in *attorneyship*. *Id.*

I will attend my husband! it is my office;
And will have no *attorney* but myself;
And therefore let me have him home. *Id.*

I am a subject,

And challenge law: *attorneys* are deny'd me;
And therefore personally I lay my claim,
To mine inheritance. *Id.*

The king's *attorney* on the contrary,
Urg'd on examinations, proofs, confessions. *Id.*

Despairing quacks with curses fled the place;
And vile *attorneys*, now an useless race. *Pope.*

An *attorney* at law answers to the procurator, or proctor, of the civilians and canonists. And he is one who is put in the place, stead, or turn of another, to manage his matters of law.

Blackstone's Commentaries.

ATTORNARE PERSONAM, in common law, to depute a representative, or proxy, to appear and act for another.

ATTORNARE REM, to turn over money and goods, that is, to assign and appropriate them to certain persons or uses.

ATTORNATO FACIENDO, vel **RECIPIENDO**, in common law, a writ to command a sheriff, or steward, to receive and admit an attorney to appear for the person that oweth suit of court, to a county or hundred. Every person that owes suit to the county court, court-baron, &c. may make an attorney to do his suit.

ATTORNEY AT LAW is one who is put in the place, stead, or turn of another, to manage his

matters at law. Formerly every suitor was obliged to appear in person, to prosecute or defend his suit (according to the old Gothic constitution,) unless by special licence under the king's letters patent. This is still the law in criminal cases; and an idiot cannot to this day appear by attorney, but in person; for he hath not discretion to enable him to appoint a proper substitute; and, upon his being brought before the court in so defenceless a condition, the judges are bound to take care of his interests, and they shall admit the best plea in his behalf that any one present can suggest. But, as in the Roman law, when it was in use, one person could not act in the name of another; yet, as this was attended with no small inconvenience, men were allowed to litigate by procurators; so with us, on the same principle of convenience, it is now permitted in general, by divers ancient statutes, whereof the first is statute West. 2, c. 10, that attorneys may be made to prosecute or defend any action in the absence of the parties to the suit. Attorneys are now, therefore, formed into a regular profession; they are admitted to the execution of their office by the superior courts of Westminster hall; are in all points officers of the respective courts in which they are admitted; and as they have many privileges on account of their attendance there, so they are peculiarly subject to the censure and animadversion of the judges. No man can practise as an attorney in any of these courts, but such as is admitted and sworn an attorney of that particular court. To practise in the court of chancery, it is also necessary to be admitted a solicitor therein; and by the statute 22 Geo. II. c. 49, no person shall act as an attorney in the court of quarter sessions, but such as has been regularly admitted in some superior court of record. So early as the statute 4 Hen. IV. c. 18, it was enacted that none should be admitted attorneys but such as were virtuous, learned, and sworn to do their duty. And many subsequent statutes have laid them under farther regulations.

By 2 Geo. II. c. 23, all attorneys shall be sworn, administered, and enrolled, before they are allowed to sue writs in the courts of Westminster; and, after the 1st of December, 1730, none shall be permitted to practise but such as have served a clerkship of four years to an attorney, and they shall be examined, sworn, and admitted in open court. Any person duly admitted a solicitor, may be admitted an attorney, and vice versa. An attorney's bill may be taxed, and if it be reduced a sixth part, he is to pay the costs of taxation.

By 34 Geo. III. c. 14, every person bound as clerk to an attorney of the courts at Westminster, pays £100 stamp duty. After admission in one court, no farther duties are required for the others. Nor are farther duties required for new contracts with new masters. An attorney is privileged from being pressed as a soldier, but he may be drawn for the militia. He need not serve any parochial or borough office against his will. They may sue and be sued only in their own courts. Special bail is not required of them as defendants; as plaintiffs they may demand it. Payment to the attorney is payment to the principal. An attorney has a lien on the

money recovered for his client, and he may retain the amount of his bill. Attornies may be summarily punished by an attachment, or by being struck off the rolls of the court for ill-practice, fraud, or corruption; and sometimes (in order to be called to the bar) they are struck off the roll on their own application.

ATTORNEY GENERAL, a great law-officer of the crown, whose business is to exhibit informations, and prosecute for the crown, in matters criminal; also to file bills in the exchequer, for any thing concerning the king in inheritance or profits; and others may bring bills against the king's attorney. His proper place in court, upon any special matters of a criminal nature, wherein his attendance is required, is under the judges on the left hand of the clerk of the crown; but this is only upon solemn and extraordinary occasions; for usually he does not sit there, but within the bar in the face of the court. The queen consort is also privileged to have an attorney-general.

ATTORNEY OF THE DUCHY COURT OF LANCASTER is the second officer in that court; placed as assessor to the chancellor of the court.

ATTORNMENT, attournor, old French, to turn over to; under the feudal system, the assent of a tenant to his lord's alienation of the seignory; thus securing him against having his fealty and services transferred to another without his knowledge. There was a reciprocal obligation on the tenant to obtain the lord's consent to any alienation.

ATTRACT' v. & n.

ATTRACTABILITY,

ATTRACTION,

ATTRACTIVE, n. & adj.

ATTRACTIVELY,

ATTRACTIVENESS,

ATTRACTOR.

Lat. *attraho, attractum*, to draw to; from *ad* and *traho*, from *trans vcho*, to carry over, *Voscius*. To draw to, bring over; to exercise a real but subtle agency in drawing an object to its subject; to conciliate, to win the heart, to gain the affections.

Setting the *attraction* of my good parts aside, I have no other charms. *Shakspeare.*

The drawing of amber and jet, and other electric bodies; and the *attraction* in gold, of the spirit of quicksilver at distance; and the *attraction* of heat, at distance; and that of fire, to naphtha; and that of some herbs to water, though at distance; and divers others, we shall handle. *Bacon.*

What, if the sun

Be centre to the world; and other stars,

By his *attractive* virtue and their own

Incited, dance about him various rounds?

Milton.

Adorn'd

She was indeed, and lovely, to *attract*

Thy love; not thy subjection. *Id.*

Loadstones and touched needles, laid long in quicksilver, have not admitted their *attraction*.

Brown's Vulgar Errors.

If the straws be in oil, amber draweth them not; oil makes the straws to adhere so, that they cannot rise unto the *attractor*. *Id.*

A man should scarce persuade the affections of the loadstone, or that jet and amber *attracteth* straws and light bodies. *Id.*

Shew the care of approving all actions so, as may most effectually *attract* all to this profession.

Hammond.

Feels darts and charms *attracts* and flames,
And woo and contract in their names. *Hudibras.*
There were then the same incentives of desire on
the one side, the same *attractiveness* in riches, the
same relish in sovereignty. *South. Sermon* xiv. 293.

Attraction may be performed by impulse, or some
other means; I use that word, to signify any force
by which bodies tend towards one another.

Newton's Opticks.

Attract, *attracted* to, the next in place,
Form'd and impell'd its neighbour to embrace.

Pope.

Deign to be lov'd, and ev'ry heart subdue!
What nymph could e'er *attract* such crowds, as you?

Id.

Homer hurries and transports us with a command-
ing impetuosity, Virgil leads us with an *attractive* ma-
jesty.

Id.

As the *attractive* power in bodies is the most uni-
versal principle which produceth innumerable effects,
so the corresponding social appetite in human souls
is the great spring and source of moral actions.

Berkeley.

Ah! why was ruin so *attractive* made,

Or, why fond man so easily betray'd?

Why heed we not, while mad we haste along,

The gentle voice of Peace, or Pleasure's song?

Collins.

Forests in every age must have had *attractive* hor-
rors: otherwise so many nations would not have
resorted thither to celebrate the rites of superstition.

Beattie.

ATTRACTION. The word attraction is em-
ployed to express the power by which bodies
approach each other; or rather that which gives
them the tendency to this approximation. It is
considered and designated differently as its opera-
tion is upon greater or less distances, and as
the masses or particles of matter are affected by
it. In the first instance, viz. that of operation
through distance, and upon mass, the power is
termed *gravitation*, while *contiguous attraction*
denotes the agency of the power as exerted upon
minute particles, and as operating upon dis-
tances that are not sensible.

All bodies composing the material system of
the universe are considered as having a mutual
disposition to approach each other, what-
ever may be the distances at which they are
placed. The nature or absolutely essential prin-
ciple of this gravitating tendency is of course
unknown; but many of its laws have been in-
vestigated and satisfactorily applied to the expla-
nation of phenomena. The main and leading
circumstances which characterise gravitation are
these, that its action on bodies is directly as the
mass or quantity of matter, and inversely as the
square of the distance. These, then, are the
laws of gravitation generally. (See GRAVITA-
TION.) But there are other species of attractions
which likewise seem to be in operation upon
mass and at distance, but which are apparently
peculiar in modification. Such are the *magnetic*
and *electric attractions*, which some philosophers,
however, are disposed to generalize into an iden-
tity with the power just adverted to. See MAG-
NETISM and ELECTRICITY.

But masses of matter are necessarily composed
of minute particles, and the power by which
this combination of separate particles into a whole
or mass is effected, is termed, as we have above

stated, contiguous attraction; this being again
subdivided into the attraction of cohesion or
aggregation; and into chemical attraction or
affinity; the former being exerted between par-
ticles of different kinds of matter: the first unites
bodies so as to form aggregates, the essential
properties of which are the same as that of the
particles which compose it; the second forming
substances which have qualities different from
those of the bodies that have entered into com-
bination.

These two varieties of contiguous attraction
may perhaps be viewed as ultimately the same
power, the difference of their effects being rather
referrible to the difference of the material operated
upon; but it is necessary to consider them dis-
tinctly, as the effects which they respectively pro-
duce, are themselves so different.

The attraction of cohesion or aggregation is
exerted with the greatest force and effect when
the body is at its maximum of solidity. In this
case the particles which compose the mass are
united by a reciprocal attraction of such energy,
that they oppose mechanical attempts at separa-
tion, as is instanced in the force required to
break a solid compact stone; but the attractive
energy seems in different states of solidification
to be exerted with different degrees of strength;
then, again, from loose solid, the gradation pro-
ceeds to absolute liquid, and ultimately to gaseous
and vaporous existence; in the ratio indeed of
departure from solidity does the attraction of
cohesion become weaker and weaker. In the
condition of fluidity 'it is only exerted under
such a modification, that a slight impulse is suffi-
cient to disunite the parts, and scarcely any re-
sistance is now opposed to any force, the opera-
tion of which is to bring these into new arrange-
ments;' and, when vaporous existence obtains,
this resistance is entirely overcome, 'the parti-
cles instead of attracting, now repel each other;
they are made to approximate only by pressure,
and they recede when this is withdrawn. Bodies,
therefore, exist in the aëiform, the liquid, or the
solid state, according as this attraction is exerted
between their particles, and it is this power which
unites their particles.'

It was supposed by the earlier philosophers,
that as the attraction of gravitation influences
bodies with a force inversely as the squares of the
distance, so the laws of attraction between the
particles themselves follow the same ratio; but
the adhesion of bodies is found to be much
greater than could be inferred from this source,
and it was therefore conceived that cohesive
attraction is governed by a much higher ratio,
and probably the cube of the distances. 'The
moderns on the contrary, among whom are
Bergman, Guyton Morveau, and others, have
remarked that these deductions are too general,
because for the most part drawn from the con-
sideration of spherical bodies, which admit of
no contact but such as is indefinitely small, and
exert the same powers on each other, whichever
side may be obverted. They remark likewise,
that the consequence depending upon the sum
of the attractions in bodies not spherical, and at
minute distances from each other, will not follow
the inverted ratio of the square of the distance'

taken from any point assumed as the centre of gravity, admitting the particles to be governed by that law; but that it will greatly differ according to the sides of the solids which are presented to each other, and their respective distances; inasmuch that the attractions of certain particles indefinitely near each other will be indefinitely increased, though the ratio of the powers acting upon the remote particles, may continue nearly the same.'—*Ure*.

Much however is requisite in application to the rationale of minute attraction, if it may be so expressed, before a generalisation of its laws can be admitted, in the same manner as is done with respect to the principle of gravitation generally. 'Speculation on these heads (says the same able author from whom we have above extracted,) may be regarded in the present state of science as standing much in the same situation as the theory of gravity, which is minutely described in Plutarch, did with regard to astronomy before the time of Newton. As the celestial phenomena were formerly arranged from observation merely, but are now computed from the physical cause, gravitation, so, at present, the science now referred to, is the science of matter of fact duly arranged, without the assistance of any extensive theory, immediately deduced from the figures, volumes, densities, or mutual actions of the particles of bodies.'

As matter of fact, however, it is necessary to observe that to the power of cohesive attraction is opposed those influences which alter the forms of bodies from solids to fluids, and from fluids to vapor; and that aggregation is thus weakened or overcome by three opposing influences, viz. mechanical violence, heat, and chemical agency. The first is instanced in the operation of powdering or pulverising, and other processes by which separation to a greater than natural distance is effected of the constituent particles of matter. With respect to heat it is to be observed, that if a solid substance be exposed to it under circumstances favorable to its action, the volume of the substance is enlarged, the particles composing it are therefore separated from each other, and the attraction by which they were kept in union is counteracted. The enlargement of volume continuing to proceed as the heat is increased, until the point is reached, at which the attraction is so far modified that the body passes into a fluid form. If the application of heat be continued, the particles are still further separated from each other; and this still continues increasing until the attraction between them is overcome, a repulsion is established, and the fluid passes into the aerial form. Chemical action, as we have above remarked, is capable of effecting the same formative change. If a liquid be poured on a solid, it often happens that from the mutual attraction exerted between them, the aggregation of the solid is subverted, its particles are detached and diffused through the liquid so as to be no longer perceptible, and not even to impair the transparency. This constitutes the chemical process named solution, which is merely a case of chemical combination, differing from others in the circumstance that one of the bodies exists in the fluid form, and communicates that form

to the other. It is the result of the predominance of the mutual affinity of the liquid and solid over the cohesion of the solid. The affinity exerted to a solid by a substance in the aerial form may in like manner overcome its cohesion and cause it to pass into the aeriform state. And even the mutual attraction exerted between two solids is sometimes such as to diminish the power of cohesion in each so as to admit of their union and their transition to a liquid state.

We have now to notice those changes in bodies, which, as opposed to their mere formative existence, may be regarded as the manifestation more directly and unequivocally of what would be called chemical agency; viz. that, in which the power is exerted between the particles or atoms of different kinds; the result of the union effected by this affinity not being a mere aggregate, having the same essential properties, though perhaps different in form, but being altogether a new material.

It is remarkable that Sir Isaac Newton was the first to indicate with precision, the nature and extent of this power, as well as that of gravitation. In his letter to Mr. Boyle, containing observations on the nature of acids, and in other publications, he speaks of bodies combining in some cases, and refusing to unite in others, because in the one instance an attraction exists, in the other it does not; and he further talks of compounds being again decomposed by the agency of another body, owing to an attraction exerted by that body to one of the principles of the compound, superior in force to the first attraction.

Since the time of Newton, the subject of chemical attraction, or the attraction of affinity, has been investigated with abundant ardor, and with great success; minute observation of its laws and the phenomena it produces, has developed a multitude of most interesting facts and principles which will fall to be noticed under the head of CHEMISTRY, and in other parts of this work. But there is one leading principle by which it is regulated that demands to be noticed in the present article; it is this, that there is a general reciprocity of saturating proportions in uniting bodies; or, in other words, that combination is effected in definite proportions; the full development of this law was made by Mr. Dalton, who has thus overturned the doctrine of indefinite affinity taught by the celebrated Berthollet, and has been successful in showing 'that the different compounds of the same principles do not pass into each other by imperceptible gradations, but proceed in successive proportions, each a multiple of the first.'

So far indeed as the fact of definite proportions goes, we ought to give the credit of discovery and detection to Richter of Berlin. Mr. Higgins too, in his Comparative View of the Phlogistic and Antiphlogistic Theory, published in the beginning of the year 1789, had plainly indicated the doctrine of multiple proportion, with respect to the successive compounds of the same constituents; but to Mr. Dalton is due the merit of having, to use the language of Dr. Wollaston, shown, 'that in all cases the simple elements of bodies are disposed to unite atom to atom singly;

or if either is in excess, it exceeds by a ratio to be expressed by some multiple of the number of its atoms.'

In the course of our researches, undertaken for the purpose of giving the reader a correct notion of this theory, we have found no statement more clear and explicit on the subject than that which we have met with in the last edition of Dr. Henry's Elements of Chemistry. We proceed, therefore, to extract largely from that section of this work which is devoted to the consideration of the atomic theory; the several objections that have been proposed to this theory, we purpose canvassing in the article CHEMISTRY, under which head many opportunities will necessarily occur of repeatedly adverting, both in direct and incidental ways, to the doctrine under notice. We shall here, however, take occasion to say, with the author from whom we are about to extract, that the instances in which the theory agrees with the results of analysis are too numerous to be considered as accidental coincidences; and no phenomena have hitherto been shown to be irreconcilable with the hypothesis. Its value and importance, if not contradicted by new facts, will be scarcely less felt as a guide to further investigations into the constitution of bodies, than as a test of the accuracy of our present knowledge; and the universality of its application to chemical phenomena, will be scarcely inferior to that of the law of gravitation, in explaining the facts of natural philosophy.

In the chemical combination of bodies with each other, says Dr. H. a few leading circumstances deserve to be remarked.

1st. Some bodies unite in all proportions; for example, water and sulphuric acid, or water and alcohol.

2dly. Other bodies combine in all proportions, as far as a certain point, beyond which, combination no longer takes place. Thus water will take up successive portions of common salt, until at length it becomes incapable of dissolving any more. In cases of this sort, as well as in those included under the first head, combination is weak and easily destroyed, and the qualities, which belonged to the components in their separate state, continue to be apparent in the compound.

3dly. There are many examples in which bodies unite in one proportion only; and in all such cases the proportion of the elements of a compound must be uniform for the species. Thus hydrogen and chlorine unite in no other proportions than those constituting muriatic acid, which, by weight, are 1 of the former to 36 of the latter. In cases of this sort, combination is generally energetic; and the characteristic qualities of the components are no longer observable in the compound.

4thly. Other bodies unite in several proportions; but these proportions are definite, and, in the intermediate ones, no combination ensues. Thus six parts by weight of charcoal combine with 8 of oxygen, or with 16, but not with intermediate quantities; 64 parts copper combine with 8 of oxygen, or with 16, and with those proportions only.

It is further remarkable, that when one body enters into combination with another, in several

different proportions, the numbers indicating the greater proportions are exactly simple multiples of that denoting the smallest proportion. In other words, if the smallest proportion in which B combines with A, be denoted by 10, A may combine with twice 10 of B, or with three times 10, and so on: but with no intermediate quantities. There cannot be more striking instances of this law than those above mentioned, of the compounds of copper and charcoal with oxygen; in which the oxygen of the last compound may, in both cases, be observed to be a multiple of that of the first by the number 2. Examples, indeed, of this kind have, of late, so much increased in number, that the law of simple multiples, first discovered by Mr. Dalton, bids fair to become universal with respect at least to chemical compounds, the proportions of which are definite.

Facts of this kind are not only important in themselves, but also on account of the generalisations that have been deduced from them; for on them Mr. Dalton has founded what may be termed the atomic theory of the chemical constitution of bodies. Till this theory was proposed, we had no adequate explanation of the uniformity of the proportions of chemical compounds; or of the nature of the cause which renders combination, in other proportions, impossible. In this place I shall offer only a brief illustration of the theory; for in the course of the work I shall have occasion to apply it to the explanation of a variety of phenomena.

Though we appear, when we effect the chemical union of bodies, to operate on masses, yet it is consistent with the most rational view of the constitution of bodies to believe, that it is only between their ultimate particles, or atoms, that combination takes place. By the term atoms, it has been already stated, we are to understand the smallest parts of which bodies are composed. The infinite divisibility of matter, indeed, against which powerful arguments before existed, has been rendered still less probable by Dr. Wollaston, in his essay on the 'Finite Extent of the Atmosphere' (Phil. Trans. 1822); all the phenomena according with the supposition that the earth's atmosphere 'is of finite extent, limited by the weight of ultimate atoms of definite magnitude, no longer divisible by repulsion of their parts.' An atom, therefore, must be mechanically indivisible, and of course a fraction of an atom cannot exist, and is a contradiction in terms.

The atoms of all bodies probably consist of a solid corpuscle, forming a nucleus, and of an atmosphere of heat, by which that corpuscle is surrounded; for absolute contact is never supposed to take place between the atoms of bodies. The figure of a simple atom may readily, therefore, be conceived to be spherical. But in compound atoms, consisting of a single central atom, surrounded by other atoms of a different kind, it is obvious that the figure (contemplating the solid corpuscles only) cannot be spherical; yet if we include the atmosphere of heat, the figure of a compound atom may be spherical, or some shape approaching to a sphere. To determine the relative diameters of the atoms of bodies is a

problem of considerable difficulty. With respect to those of elastic fluids, it was some time ago effected by Mr. Dalton (*New Syst.* p. 226), and the same principle has been lately extended by Mr. Emmett to solid and liquid bodies. (*Ann. Phil. N. S.* ix. 110).

Taking for granted that combination takes place between the atoms of bodies only, Mr. Dalton has deduced, from the relative weights in which bodies unite, the relative weights of their ultimate particles, or atoms, which is all that we are likely to determine respecting them;

1 atom of A + 1 atom of B	= 1 atom of C, binary.
1 atom of A + 2 atoms of B	= 1 atom of D, ternary.
2 atoms of A + 1 atom of B	= 1 atom of E, ternary.
1 atom of A + 3 atoms of B	= 1 atom of F, quaternary.
3 atoms of A + 1 atom of B	= 1 atom of G, quaternary.

A different classification of atoms has been proposed by Berzelius, viz. 1st, elementary atoms; 2dly, compound atoms. The compound atoms he divides again into three different species, viz. 1st, atoms formed of only two elementary substances united, or compound atoms of the first order: 2dly, atoms composed of more than two elementary substances; and these, as they are only found in organic bodies, or bodies obtained by the destruction of organic matter, he calls organic atoms: 3dly, atoms formed by the union of two or more compound atoms; as for example, the salts. These he calls compound atoms of the second order.

If elementary atoms of different kinds were of the same size, the greatest number of the atoms of A that could be combined with an atom of B would be 12; for this is the greatest number of spherical bodies that can be arranged in contact with a sphere of the same diameter. But this equality of size, though adopted by Berzelius, is not necessary to the hypothesis of Mr. Dalton, and is, indeed, supposed by him not to exist.

As an illustration of the mode in which the weight of the atoms of bodies is determined, let us suppose that any two elementary substances, A and B, form a binary compound; and that they have been proved experimentally to unite in the proportion, by weight, of 5 of the former to 4 of the latter; then, since, according to the hypothesis, they unite particle to particle, those numbers will express the relative weights of their atoms. But besides combining atom to atom singly, 1 atom of A may combine with 2 of B, or with 3, 4, &c. Or 1 atom of B may unite

1. In water, the hydrogen is to the oxygen as 1 to 8.
2. In olefiant gas, the hydrogen is to the carbon as 1 to 6.
3. In carbonic oxide, the oxygen is to the carbon as 8 to 6.

Whether, therefore, we determine the weight of the atom of carbon, from the proportion in which it combines with hydrogen, or with oxygen, we arrive at the same number 6: an agreement which, as it occurs in various other instances, can scarcely be an accidental coincidence. In a similar manner, 8 is deducible, as representing the atom of oxygen, both from the combination of that base with hydrogen and with carbon; and 1 is inferred to be the relative weight of the atom of hydrogen from the two principal compounds into which it enters.

for it is not probable that our knowledge will ever extend beyond the ratios of these weights. When only one combination of any two elementary bodies exists, he assumes, unless the contrary can be proved, that its elements are united atom to atom singly. Combinations of this sort he calls binary. But if several compounds can be obtained from the same elements, they combine, he supposes, in proportions, expressed by some simple multiple of the number of atoms. The following table exhibits a view of some of these combinations:

with 2 of A, or with 3, 4, &c. When such a series of compounds exists, the relative proportion of their elements ought necessarily, on analysis, to be proved to be 5 of A to 4 of B; or 5 to (4 + 4 =) 8; or 5 to (4 + 4 =) 12, &c.; or contrariwise, 4 of B to 5 of A; or 4 to (5 + 5 =) 10; or 4 to (5 + 5 + 5 =) 15. Between these there ought to be no intermediate compounds: and the existence of any such (as 5 of A to 6 of B, or 4 of B to 7½ of A) would, if clearly established, militate against the hypothesis.

To verify these numbers, it may be proper to examine the combinations of A and B with some third substance, for example, with C. Let us suppose that A and C form a binary compound, in which analysis discovers 5 parts of A and 3 of C. Then, if C and B are also capable of forming a binary compound, the relative proportion of its elements ought to be 4 of B to 3 of C; for these numbers denote the relative weights of their atoms. Now this is precisely the method by which Mr. Dalton has deduced the relative weights of oxygen, hydrogen, and nitrogen; the two first from the known composition of water, and the two last from the proportion of the elements of ammonia. Extending the comparison to a variety of other bodies, he has obtained a scale of the relative weights of their atoms.

In several instances, additional evidence is acquired of the accuracy of the weight, assigned to an element, by our obtaining the same number from the investigation of several of its compounds. For example:

In selecting the body, which should be assumed as unity, Mr. Dalton has been induced to fix on hydrogen, because it is that body which unites with others in the smallest proportion. Thus, in water, we have 1 of hydrogen by weight to 8 of oxygen; in olefiant gas, 1 of hydrogen to 6 of carbon; and in sulphureted hydrogen, 1 of hydrogen to 16 of sulphur. Taking for granted that all these bodies are binary compounds, we have the following scale of numbers, expressive of the relative weights of the atoms of their elements:

Hydrogen	1
Oxygen	8
Carbon	6
Sulphur	16

Drs. Wollaston and Thomson, and Professor Berzelius, on the other hand, have assumed oxygen as the decimal unit (the first making it 10, the second 1, and the third 100), chiefly with a view to facilitate the estimation of its numerous compounds with other bodies. This, it appears to me, is to be regretted, even though the change may be in some respects for the better, because it is extremely desirable that chemical writers should employ an universal standard of comparison for the weights of the atoms of bodies. It is easy, however, to reduce their numbers to Mr. Dalton's by the rule of proportion. Thus as 8 (Mr. Dalton's number for oxygen, corrected by the latest experiments), is to 1 (his number for hydrogen), so is 10 (Dr. Wollaston's number for oxygen), to 1.25, the number for hydrogen.

Sir H. Davy has assumed, with Mr. Dalton, the atom of hydrogen as unity: but that philosopher, and Berzelius also, have modified the theory, by taking for granted that water is a compound of one proportion (atom) of oxygen, and two proportions (atoms) of hydrogen. This is founded on the fact, that two measures of hydrogen gas, and one of oxygen gas, are necessary to form water; and on the supposition, that equal measures of different gases contain equal numbers of atoms. And as, in water, the hydrogen is to the oxygen by weight as one to eight, two atoms or volumes of hydrogen must, on this hypothesis, weigh one, and one atom or volume of oxygen eight; or if we denote a single atom of hydrogen by one, we must express an atom of oxygen by sixteen. It is objectionable, however, to this modification of the atomic theory, that it contradicts a fundamental proposition of Mr. Dalton, the consistency of which with mechanical principles he has fully shown; namely, that that compound of any two elements, which is with most difficulty decomposed, must be presumed, unless the contrary can be proved, to be a binary one.

It is easy to determine, in the manner already explained, the relative weights of the atoms of two elementary bodies, which unite only in one proportion. But when one body unites, in different proportions, with another, it is necessary, in order to ascertain the weight of its atom, that we should know the smallest proportion in which the former combines with the latter. Thus, if we have a body A, 100 parts of which, by weight, combine with not less than thirty-two of oxygen, the relative weight of its atom will be to that of oxygen as 100 to thirty-two; or, reducing these numbers to their lowest terms, as twenty-five to eight; and the number twenty-five will, therefore, express the relative weight of the atom of A. But if, in the progress of science, it should be found, that 100 parts of A are capable of uniting with sixteen parts of oxygen, then the relative weight of the atom of A must be doubled; for as 100 is to sixteen, so is fifty to eight. This example will serve to explain the changes that have been sometimes

made in the weights of the atoms of certain bodies; changes which, it may be observed, always consist either in the multiplication or division of the original weight by some simple number.

There are, it must be acknowledged, a few cases in which one body combines with another in different proportions; and yet the greater proportions are not multiples of the less, by any entire number. For example, we have two oxides of iron, the first of which consists of 100 iron and about thirty oxygen; the second of 100 iron and about forty-five oxygen. But the numbers thirty and forty-five are to each other as one to one and one-half. It will, however, render these numbers (one and one-half) consistent with the law of simple multiples, if we multiply each of them by two, which will change them to two and three; and if we suppose that there is an oxide of iron, though it has not yet been obtained experimentally, consisting of 100 iron and fifteen oxygen; for the multiplication of this last number by two and three, will then give us the known oxides of iron.

In some cases, the peroxide of iron for instance, where we have the apparent anomaly of one atom of one substance, united with one and one-half of another, it has been proposed by Dr. Thomson, *Annals of Philosophy*, p. 87, to remove the difficulty, by multiplying both numbers by two; and by assuming that, in such compounds, we have two atoms of the one combined with three atoms of the other. Such combinations, it is true, are exceptions to a law deduced by Berzelius; that in all inorganic compounds, one of the constituents is in the state of a single atom. But they are in no respect inconsistent with the views of Mr. Dalton; and are, indeed, expressly admitted by him to be compatible with his hypothesis, as well as confirmed by experience.

The reader is referred to an able account of the atomic theory, published by Mr. Ewart, in the sixth volume of Thompson's *Annals*. Under the word *Equivalents* too, in *Ure's Dictionary of Chemistry*, the subject will be found handled in a masterly manner.

On elective affinity, or the unequal, and selecting attraction of bodies, and on the causes which modify this action, both in a simple and complex manner, let the reader consult the article *CHEMISTRY*, in the present work.

ATTRACTIVES, or ATTRACTIVE REMEDIES, medicines which are to be externally applied, and which by their activity and warmth penetrate the pores, mix with, and rarefy, any obstructed matter, so as to render it fit for discharge, upon laying open the part by a caustic or incision.

ATTRAHENTS, in medicine, are the same with maturants, digestives, &c.

ATTRAP'. Fr. *attraper*, to catch, seize, apprehend, over-reach; used as we now use *entrap*. See *TRAP*.

But Richard his brother being an expert and politique man, so craftily conveyed, and so wisely ordered himself in his stormy tempest, that he was not *atrapped* either with net or snare. *Grafton*, v. 2.

For, all his armour was like salvage weed
With oaken mosse bedight, and all his steel
With woody leaues *atrapped*, that seemed fit
For salvage weight. *Spenser's Faerie Queene*.

ATTRIBUTE,
ATTRIBUTABLE,
ATTRIBUTION,
ATTRIBUTIVE, n. & adj. } Lat. *attribuo*, from
ad and *tribuo*, to lay
 a thing to. To ap-
 portion, to give a
 proper share; to yield as due, to impute, to
 ascribe, assign, charge.

It (*envy*) is also the vilest affection, and the most depraved; for which cause it is the *attribute* of the Devil, who is called the envious man, that soweth tares amongst the wheat by night: as it always cometh to pass, that Envy worketh subtly, and in the dark, and to the prejudice of good things, such as is the wheat.

Lord Bacon's Essays.

It takes

From our achievements, tho' perform'd at height,
 The pith and marrow of our *attribute*. *Shakspeare.*

If speaking truth,

In this fine age, were not thought flattery;
 Such *attribution* should the Douglas have,
 As not a soldier of this season's stamp,
 Should go so general current through the world.

Id.

We suffer him to persuade us we are as gods; and never suspect, these glorious *attributions* may be no more than flattery. *Decay of Piety.*

We *attribute* nothing to God, that hath any repugnancy or contradiction in it. Power and wisdom have no repugnancy in them. *Tillotson.*

Much of the origination of the Americans seems to be *attributable* to the migrations of the Seres. *Hale.*

Your vain poets after did mistake,

Who ev'ry *attribute* a god did make. *Dryden.*

All the perfections of God are called his *attributes*; for he cannot be without them. *Watts's Logick.*

I have observed a *campania determino*, contrary to appearances, by the caution and conduct of a general, which were *attributed* to his infirmities. *Temple.*

The imperfection of telescopes is *attributed* to spherical glasses; and mathematicians have propounded, to figure them by the conical sections. *Newton's Opticks.*

As to be perfectly just is an *attribute* of the Divine Nature; to be so, to the utmost of our abilities, is the glory of a man. *Addison.*

Perhaps it may appear upon examination that the most polite ages are the least virtuous. This may be *attributed* to the folly of admitting wit and learning as merit in themselves, without considering the application of them. *Steele.*

Benevolence, would the followers of Epicurus say, is all founded on weakness; and whatever is pretended the kindness between men and men, is by every man directed to himself. This, it must be confessed, is of a piece with that hopeful philosophy which having patched man up out of the four elements, *attributes* his being to chance. *Grove.*

ATTRIBUTE, in physics, a quality determining something to be after a certain manner. Thus understanding is an attribute of mind, and extension an attribute of body. That attribute which the mind conceives as the foundation of all the rest is called its essential attribute; thus extension is by some, and solidity by others, esteemed the essential attributes of body or matter.

ATTRIBUTES, in logic, the predicates of any subject, or what may be affirmed or denied of any thing.

ATTRIBUTES, in painting and sculpture, symbols added to several figures to intimate their particular office and character. Thus the eagle

is an attribute of Jupiter; a peacock, of Juno; a caduceus, of Mercury; a club, of Hercules; and a palm, of Victory.

ATTRIBUTES, in grammar, are words which are significant of attributes; and thus include adjectives, verbs, and particles, which are attributes of substances; and adverbs, which denote the attributes only of attributes. Mr. Harris, who has introduced this distribution of words, denominates the former attributes of the first order, and the latter attributes of the second.

ATTRITE, } Lat. *attero*, *attritum*, to rub
ATTRITION. } against; *ad* and *tero*, to beat
 small, to wear out by rubbing. The act of rubbing used figuratively by theological writers.

Or, by collision of two bodies, grind

Their air *attrite* to fire. *Milton.*

From these premises it follows, that if the priest can absolve him that is *attrite*, he may pardon him who hath affections to sin still remaining; that is, one who fears hell, but does not love God.

Taylor's Polemical Discourses.

Attrition is a trouble for sin, merely for fear of the punishment of it. *Tillotson.*

This vapour, ascending incessantly out of the abyss, and pervading the strata of gravel and the rest, decays the bones and vegetables lodged in those strata; this fluid, by its continual *attrition*, fretting the said bodies. *Woodward.*

The change of the aliment is effected, by *attrition* of the inward stomach, and dissolvent liquor, assisted with heat. *Arbuthnot.*

ATTROW, in botany, a name given by the people of Guinea to a plant which they use in cases of swellings, boiling the leaves in water, and using the decoction by way of a fomentation. It is a species of kali, and is called by Petiver, kali Guineense foliis polygoni, floribus verticilli in modum dispositis, from its leaves resembling the common knot-grass, and its flowers growing in rundles round the stalks.

ATTRUMAPHOC, in botany, a name given by the people of Guinea to a shrub which they boil in water, and give the decoction in the venereal disease. The juice, when fresh pressed out, is snuffed up the nostrils to promote sneezing, and cure disorders of the head and eyes. It is a species of colutea. Dr. Heriman calls it astragalus.

ATTUAL, a town of Arabia, in Tehama, in the province of Yemen. Long. 42° 10' E., lat. 15° 57' N.

ATTUDSJE, a town of Arabia, in Yemen, between Kusma and Sai-id. Long. 43° 25' E., lat. 14° 40' N.

ATTUE, a fort of Arabia, in Tehama, seated on the coast of the Arabic Gulf. Long. 41° 40' E., lat. 17° 37' N.

ATTUNE. To tune, to set to a tune.

Airs, vernal airs,

Breathing the smell of field and grove, *attune*
 The trembling leaves. *Milton.*

Th' ethereal glow that stimulates thy frame,
 When all th' according powers harmonious move,
 And wake to energy each social aim,
 Attuned spontaneous to the will of Jove;
 Be these, O man, the triumphs of thy soul.

Beattie. Judgment of Paris.

ATTURNATUS, in old law Latin, an attorney.

ATURÆ, a town of ancient Gaul, in the district of Novempopulana in Aquitania, on the Aturus; now called Aire. Long. 0° 16' E., lat. 43° 42' N.

ATURUS, a river of ancient Gaul in Aquitania, now called the Adour.

ATWAINĒ,
ATWĒ'N,
ATWIXT,
ATWO. } In twain, in two. Gothic
 } twos, two.

And Jhesus gaf out a great cry and diede. And the veyl of the temple was to rend a two from the higheste to bynethe. *Wiclif. Mark, c. xv.*

And with that word he gan sigh as sore,
Like as his heart rive would atwaine,
And held his peace, and spake no more.

Chaucer. The Complaint of the Black Knight.

Her loose long yellow locks (like golden wire,
Sprinkled with pearl, and perling flowers atween)
Do, like a golden mantle, her attire. *Spenser.*

With them an hideous storm of wind arose
With dreadful thunder, and lightning atwixt,
And an earthquake, as if it straight would loose,
The world's foundations from its centre fixt.

Id. Faerie Queene, b. ii.

ATWOOD (George), a celebrated author in mathematical and mechanical investigations, was born in the early part of the year 1746. He was educated at Westminster school, where he was admitted in 1759. Six years afterwards he was elected to Trinity college, Cambridge, and took his degree of Bachelor of Arts in 1769, with the rank of third wrangler. This distinction was amply sufficient to give him a claim to further advancement in his own college, on the list of which he stood foremost of his contemporaries; and, in due time, he obtained a fellowship, and was afterwards one of the tutors. He became Master of Arts in 1772; and, in 1776, was elected a Fellow of the Royal Society of London. The higher branches of the mathematics having previously made some important advances at Cambridge, under the auspices of Dr. Waring, Mr. Atwood delivered, for several successive years, a course of lectures in the observatory of Trinity college, which were very generally attended. In 1784, or soon afterwards, Mr. Pitt, who had become acquainted with his merits by attending his lectures, bestowed on him a patent office, which required but little of his attendance, in order to have a claim on the employment of his mathematical abilities in financial calculations. He died universally respected in 1807. The following, we believe, is a correct list of Mr. Atwood's publications:—
1. A Description of Experiments to illustrate a Course of Lectures, 8vo. 1775, or 1776. 2. This work was reprinted with additions, under the title of An Analysis of a Course of Lectures on the Principles of Natural Philosophy, 8vo. Cambridge, 1784. 3. A General Theory for the Mensuration of the Angle subtended by two objects, of which one is observed by Rays after two Reflections from plane Surfaces, and the other by Rays coming directly to the Spectator's Eye. Phil. Trans. 1781, p. 395. 4. A Treatise on the Rectilinear Motion and Rotation of

Bodies, with a Description of Original Experiments relative to the Subject, 8vo. Cambridge, 1784. 5. Investigations founded on the Theory of Motion, for determining the Times of Vibration of Watch Balances. Phil. Trans. 1794. p. 119. 6. The Construction and Analysis of Geometrical Propositions, determining the positions assumed by homogeneous bodies, which float freely, and at rest, on a fluid surface; also Determining the Stability of Ships, and of other Floating Bodies. Phil. Trans. 1796, p. 46. 7. A Disquisition on the Stability of Ships. Phil. Trans. 1798, p. 201. 8. A Review of the Statutes and Ordinances of Assize, which have been established in England from the 4th year of King John, 1202, to the 37th of his present Majesty, 4to. London, 1801. 9. A Dissertation on the Construction and Properties of Arches 4to. London, 1801. 10. A Supplement to a Tract entitled a Treatise on the Construction and Properties of Arches, published in the year 1801; and containing Propositions for Determining the weights of the several sections which constitute an arch, inferred from the angles. Also containing a Demonstration of the angles of the several sections, when they are inferred from the weights thereof. To which is added, a Description of original experiments to verify and illustrate the principles in this treatise. With occasional remarks on the construction of an iron bridge of one arch, proposed to be erected over the river Thames at London. Part II. By the author of the first part, 4to. London, 1804. Dated 24th Nov. 1803. 11. A Treatise on Optics is mentioned by Nichols, as having been partly printed by Bowyer, in 1776, but never completed.

ATYCHIA, in entomology, a genus of insects of the order lepidoptera, and family zygænidæ. Its generic characters are: palpi ring considerably beyond the clypeus, anteriorly very hirsute with long hairs, wings short; posterior tibiæ with scales and elongated spurs.

ATYPOS; from α negative, and τυπος, form; irregular, a word used by the old writers in medicine, for such diseases as did not observe any regularity in their periods. Others have used the word for deformities in the limbs; and others for defects in the organs of speech.

ATYPUS, in entomology, a genus of the class arachnides, order acera, and family araneides. Its generic characters are: eyes on each side geminate; labium inserted under the base of the maxillæ, very small, quadrate; palpi placed at the base of the external dilatation of the maxillæ. The A. sulzeri has been found in this country by Dr. Leach, and inhabits turfey declivities, where it forms a deep cylindrical excavation, seven or eight inches long, in which it weaves a kind of funnel of white silk. The cocoon in which the eggs are deposited, is fixed at the bottom of this cavity by means of threads attached to each end.

ATYS, the son of Cræsus, king of Lydia, is reported to have been born tongue-tacked, and of consequence to have been dumb for many years; till observing one of Cyrus's soldiers going to kill his father, his passion suddenly broke the membrane that held his tongue, and he cried out 'Save the king!'

ATYS, in fabulous history, a celebrated shepherd of Phrygia, with whom Cybele, commonly called the mother of the gods, fell passionately in love. She gave him the care of her temple, at the same time making him vow he would always live in celibacy. He afterwards violated his promise by an amour with the nymph Sangaris, on which account the goddess brought upon him such a species of insanity which made him castrate himself with a sharp stone. The same operation was purposely performed by his sacerdotal successors, in the service of Cybele, that their vows of perpetual chastity might not be broken. This is the most generally received account; though, according to some writers, the cause of the fondness of the goddess for Atys, was his introducing her festivals into the greatest part of Asia Minor; and that she herself mutilated him. From Pausanias we learn that Atys was the son of a nymph of the Sangar, who became pregnant by placing the branch of an almond tree in her bosom. According to the passage (Achaic. c. 17), Jupiter having had an amorous dream, some of the impurity of the god dropt upon the earth, from which a monster of an human form was produced, with the parts of both sexes. This monster was named Agdistis, and was by the gods deprived of the characteristics of the male sex. The mutilated parts having been thrown on the ground, an almond tree sprung from them, a branch of which one of the daughters of the Sangar took and put in her bosom. As soon as Atys was born, he was exposed in a wood, where a she-goat nourished and preserved him. While in the wood, he was observed by Agdistis, who was captivated with his beauty; and when Atys was about to celebrate his nuptials with the king of Pessinus's daughter, Agdistis, jealous of a rival, infused into the king and his intended son-in-law such a spirit of madness as led them to attack and mutilate one another in the struggle. We farther learn from Ovid, that as Atys was going to his violent hands upon himself, he was changed by Cybele into a pine-tree; and that from that time the pine-tree was held sacred to the mother of the gods. Divine honors were paid to Atys after his death, and temples erected to his memory, among which that at Dymæ was the most famous.

ATYS, a Trojan, who accompanied Æneas to Italy, and from whom it is supposed the family of the Atii at Rome descended.

AVA, or ANGWA, a city of the Birman empire, four miles west of Ummurapura, the metropolis. It is in lat. 21° 51' N., and long. 95° 58' E.; and was once the capital, but is now in ruins. Here are two large temples, one of which contains an image of Gaudma, Gautama, or Buddha, twenty-four feet in height, and ten feet across the breast. There are also the reliques of many other temples in decay. For AVA, as an empire, see BIRMAN EMPIRE, its more usual and modern designation.

AVA-AVA, a plant, so called by the inhabitants of Ouhente, from the leaves of which they express an intoxicating juice. It is drunk very freely by their chiefs, who mix with each other in drinking the greatest number of draughts, each draught being about a pint; but they keep it constant from their women.

AUACII, or AVACH, the ancient name of Avach.

AUAD, a mountainous district of Arabia, in the province of Yemen, near the city of Udden. Long. 44° 10' E., lat. 14° 5' N.

AVACHIA, AWATSCHIA, a considerable river of Kamschatka, falling, after a course of ninety miles from west to east, into a bay which bears the same name. Its mouth is rather narrow, but deep enough to admit ships of the greatest burden, and abounding in good anchorage; the best of which is the harbour of St. Peter and St. Paul. On the north side of the bay is the Volcano of Avacha, which constantly smokes, though it has had no considerable eruption since 1734, and that only lasted twenty-four hours. A small town called the Avachinski Ostrog was begun in 1740; it is in a tolerably flourishing state, and principally supported by the trade in beaver skins. The river Avacha has a course of about ninety miles.

AVADOUTAS, a sect of Indian Brahmins, who in austerity surpass all the rest. The other sects retain earthen vessels to hold their provisions, and a stick to lean on: but none of these are used by the Avadoutas; they only cover their nakedness with a piece of cloth, and some of them even lay that aside, and go stark naked, besmearing their bodies with cow-dung! When hungry, some go into houses, and, without speaking, hold out their hand; eating on the spot whatever is given them. Others retire to the sides of holy rivers, and there expect the peasants to bring them provisions, which they generally do very liberally.

AVAIL, *v. & n.* } Fr. *valoir*, to be worth;
 AVAIL'ABLE, } Lat. *valeo*, to be strong, to
 AVAIL'ABLENESS. } be in health. To possess
 advantageous properties; to be of force or signification. The *a* is intensive.

All things subject to action, the will does so far incline unto; as reason judges them more *available* to our bliss.

Hooker.

Laws human are *available* by consent.

Id.

Drake put one of his men to death, having no authority nor commission *available*.

Raleigh.

For all that else did come, were sure to fail;

Yet would he further none, but for *avail*.

Spenser.

I charge thee,

As heav'n shall work in me for thine *avail*,

To tell me truly.

Shakspeare

We differ, from that supposition of the efficacy, or *availableness*, or *suitableness*, of these to the end.

Hale.

Those excellent means God has bestowed on us, well employed, cannot but much *avail* us: but if otherwise perverted, they ruine and confound us.

Burton's Anatomy of Melancholy.

Truth light upon this way, is of no more *avail* to us than error.

Loche.

Nor can my strength *avail*; unless, by thee

Endu'd with force, I gain the victory.

Dryden.

When real merit is wanting; it *avails* nothing, to have been encouraged by the great.

Pope's Preface to his Works.

Mean time he voyag'd, to explore the will

Of Jove, on high Dodona's holy hill;

What means might best his safe return *avail*.

Pope.

Ah! what *avails* the lore of Rome and Greece,
All that art, fortune, enterprise can bring,
If envy, scorn, remorse, or pride, the bosom wring.

Beattie.

AVAIL OF MARRIAGE, in ancient Scot's law, that casualty in inward-holding, by which the superior was entitled to a certain sum from his vassal, upon his attaining the age of puberty, or fourteen years, as the avail and value of his tocher.

AVAL, or **BAHREIN**, the largest of the Bahrein islands in the gulf of Persia. It is about thirty miles in length, and twelve wide, where it is broadest. Besides the fortified town of Bahrein, it contains about sixty poor villages. Long. 48° 4' E., lat. 26° 36' N.

AVALANCHES, prodigious masses of snow and ice that roll down the mountains in Savoy, particularly mount Blanc, to the extreme danger of travellers.

'Oft rushing sudden from the loaded cliffs,
From steep to steep, loud thund'ring down they come,
A wintry waste in dire commotion all;
And herds and flocks, and travellers and swains,
And sometimes whole brigades of marching troops,
Or hamlets sleeping in the dead of night,
Are deep beneath the smothering ruin hurl'd.'

Some of them are 150 or 200 feet diameter; being fragments of the ice-rocks which break by their own weight from the tops of the precipices. See **BLANC**, MOUNT.

AVALON, or **AVALLON**, the chief town of an arrondissement in the department of the Yonne in France, situated, with its strong castle, on the river Cousin. Population 4200; that of the arrondissement is 42,800. It is twenty leagues west of Dijon.

AVALON, or **AVOLON**, a peninsula of Newfoundland.

AVALON, or **AVALONIA**, the ancient name of Glastonbury, where king Arthur was buried. See **ARTHUR**, and **GLASTONBURY**.

AVALOS (Ferdinand Francis d'), marquis of Pescara, was born in the kingdom of Naples. He entered into the service of Charles V. and accompanied the army to the battle of Ravenna, where he was made prisoner. During his captivity he amused himself in writing a Dialogue on Love, and dedicated it to his wife. After his release he again entered into the emperor's service, and was present at the taking of Milan, where he died in 1525, aged thirty-six.

AVALOS (Alphonso d'), marquis del Vasto, was born in 1502. He was a near relation of the above; and was likewise a zealous officer in the armies of Charles V. He died in 1546.

AVANIA, in the Turkish legislature, a fine for crimes, and on deaths, paid to the governor of the place. In the places wherein several nations live together under a Turkish governor, he takes this profitable method of punishing all crimes among the Christians or Jews, unless it be the murder of a Turk.

AVANT, the front of an army. See **VAN**.

AVANT is defined by Mr. Chalmers, a French preposition, signifying before, or any priority in respect of time or place; sometimes used in composition, in our language, but more usually contracted, and wrote vaunt, vant, or van.

AVANT FOSSE, &c. See **VAN FOSSE**.

AVANT-GUARD, *avantgarde*, French. The van or the first body of an army.—The horsemen might issue forth without disturbance of the foot, and the *avant-guard* without shuffling with the *battail* or *arriere*.—*Hazard*.

AVANT MURE, an outward wall.

AVANT PEACH, a peach early ripe.

AVANT WARD, the van of an army.

AVANTE, among ancient medical authors, a name given to a disease, seeming, from their accounts of it to be the same with *hypochondriasis*.

AVANTIO (John Mario), an Italian lawyer of great eminence, born in 1564. He displayed his abilities first at Ferrara, and afterwards at Padua; at which last place he died in 1622. Besides several other pieces, he wrote an ecclesiastical history, from the commencement of the reformation.

AVANTIO (Charles), a celebrated physician, was a son of the above. He was author of a commentary on the work of Bapt. Fiera, printed at Padua, in 1649.

AVANTURINE, in mineralogy, a species of common quartz, containing a number of minute fissures, and sometimes crystals of mica. These lie in parallel, or nearly parallel planes: so that when the stone is cut into a double convex figure, the imaginary plane of junction of the two spherical segments being parallel to the planes in which the fissures lie, a play of light is produced on the surface of the stone. The most beautiful varieties have been found in Spain.

AVARA, a river of Gallia Celtica, mentioned by Cæsar, in the county of Brituriges, now called *Aruon*.

AVARES, one of the predatory tribes in the north of Asia Minor, who made great ravages in the eastern empire. Having penetrated the Slavonian and Greek territories, they first appeared on the banks of the Danube, A. D. 560, and established themselves at Sirmium, and in Upper Hungary. Their riches, and their alliance with Thassilo, chief of the Baii, alarmed Charlemagne, who, in A. D. 803, attacked them in person, and drove them into Corinthia. They have been conjectured to be the Aorsi, or Adorsi, of Strabo.

There is still on the banks of the Kóijú, in Lezgistan, and on the eastern side of Mount Caucasus, a tribe called Aor or Avar, whose language is a peculiar one, but has an affinity with several others used in the neighbouring districts. There is also a city of this name consisting of about 600 houses, the residence of a hereditary prince or chief. He has considerable influence; and, on a late occasion, a neighbouring potentate purchased his sister in marriage for £25,000. In his palace, the only one with glass windows in eastern Caucasus, there is a large hall, well provided with provisions, constantly open to all strangers. In the city of Avar fine shawls are manufactured from the wool of Caucasian sheep; one of which, an ell and a half long, may be drawn through a ring. These people are warlike and courageous; and their chief, the Avar Khán, is much courted by the Russians. He was raised to the rank of a lieutenant-general, with a pension of 10,000 silver rubles (£2000)

in 1807. He can bring 20,000 men into the field, and his dependant khan 10,000 more.

AVARIA, in the Turkish and Persian dominions, a sum of money exacted from the Christians or Europeans, to be quit of some false accusation framed on purpose.

AV'ARICE, } Lat. *avaritia*, *avarus* ;
 AVARIC'IOUS, } from *avare*, to covet, to
 AVARIC'IOUSLY, } desire greedily. Applied
 AVARIC'IOUSNESS, } to one whose ruling pas-
 AV'AROUS. } sion is the acquisition of
 wealth for its own sake.

Now good men ! God forgive you your trespass,
 And ware you fro the sinne of *avarice*,
 Min holy pardon may you all warice ;
 So that ye offre nobles or starlings,
 Or elles silver broches, spones, ringes.

Chaucer. Pardeneres Tale.

But father I herde you say
 How the *avorous* hath yet some way
 Whereof he maie be glad. For hee
 Maie, whan hym list, his tresure see,
 And grope, and fele it all aboute.

Gower. Con. A. book v.

This speech has been condemned as *avaricious* ; and Eustathius judges it to be spoken artfully.

Broome on the Odyssey.

Luxurious, *avaricious*, false, deceitful.

Shaksp. Macbeth.

There grows
 In my most ill-compos'd affection, such
 A staunchless *avarice* ; that, were I king,
 I should cut off the nobles for their lands.

Shakespeare.

This *avarice* of praise in times to come ;
 Those long inscriptions, crowded on the tomb.

Dryden.

Nor love his peace of mind destroys,
 Nor wicked *avarice* of wealth.

Id.

Avarice is insatiable ; and so he went, still pushing
 on for more.

L'Estrange.

Though the apprehensions of the aged may justify
 a cautious frugality, they can by no means excuse a
 sordid *avarice*.

Blair.

An insatiable thirst of riches renders Pygmalion
 every day more wretched and detestable. In his do-
 minions it is a crime to be wealthy : *avarice* makes
 him jealous, suspicious, and cruel : he persecutes
 the rich, and he dreads the poor.

Hawkesworth's Telemachus.

AVARICE, of all the various passions by which
 mankind is governed, is the least to be accounted
 for, as it precludes its subject from all pleasure
 except that of hoarding. The ambitious man,
 the gamester, or even the prodigal, have all
 something to plead, by way of palliative for their
 inordinate affections to their respective objects
 and pursuits ; but the subject of avarice gratifies
 his passion at the expense of every conveniency,
 indulgence, or even necessary of life. And
 though convinced that money is only the means
 of enjoyment, not the end, and that it is only
 valuable as far as it is useful for attaining that
 end, yet such is his infatuation, that the images
 of his bags and shining metal, with all the an-
 nexed ideas of property, enjoyment, security
 against want, independence, &c. prevent him
 from using the means, and make him appear
 wretched, in misery, in want, and de-
 pendent. No passion is more opposite to the
 hope of a future life than avarice.

AVARICUM, an ancient town of the Bituriges
 in Gallia Celtica, situated on the Avara, in a very
 fertile soil ; now called Bourges. Long, 2° 28' E.,
 lat. 47° 5' N.

AVAROMO Temo, in botany, a siliquose
 tree, which grows in the Brasils. The bark is
 externally of a cineritious, and internally of a
 deep red color, and is the only part of the plant
 used for medicinal purposes, though some indeed
 use the leaves. But the bark, which is bitter,
 whether reduced to a powder, or boiled and used
 as a fomentation, cures inveterate ulcers, and, it
 is said, has been found to cure even cancers. It
 is also used as a corroborant, on account of its
 astringent quality, by way of bath.

AVAST, from *basta*, Ital. it is enough : enough ;
 cease. A word used among seamen. It always
 precedes some orders, or some conversation, and
 answers the same purpose as—*harkye*, list, attend,
 take heed, hold. Like the Ital. *avacci*, I think
 it means—be attentive, be on the watch, &c.
 awake.—*Tooke*, ii. 362.

AVATAR, in the Hindoo mythology, an incar-
 nation of the Deity. Ten of these are incarna-
 tions of Vishnú, the supreme God, in his cha-
 racter of preserver. Four are the subjects of
 Puranas, or sacred poems. Nine of them are
 believed to be past, and the tenth is yet to come.

The first is the Matsya Avatár, or descent of
 the deity in the form of a fish. Of what species
 this fish was, the sages have not determined ; but
 Vishnú's object was the recovery of the holy Vedas
 from the ocean, in which they remained after
 one of the periodical dissolutions of the universe.

The second is the Kachyapa, or Kúrma Avatár,
 in which the same god appeared in the form of a
 tortoise, in order to sustain and give stability to
 the newly created earth.

The third is the Varáha Avatár, when he ap-
 peared in the shape of a boar, and plunging into
 the waters which had overwhelmed the earth, in
 one of its periodical destructions, fixed his tusks
 in it and drew it up.

The fourth is the Nara-sing'ha, or man-lion
 Avatár. Kas'yapa, one of the descendants of
 Daksha, the first created man, had two wives,
 whose characters, to judge from their children,
 were very different, for one produced the gods,
 and the other the giants. Among the latter
 were two Hiranyáksha and Hiranyakas'ipu, who
 it seems stole a march on Brahmá, and almost
 compelled him, by dint of their austerities, to
 grant what he had no mind to give them—im-
 mortality. Their strength was already quite
 terrific, so that to give it an endless duration
 was more than the god thought prudent. How-
 ever, he could not resist the claim of austerities
 practised for some thousands of years, and,
 therefore, to release himself from this dilemma,
 he engaged that no ordinary being should destroy
 them ; and that they should not die either by
 day or by night, in earth or in heaven, by fire,
 by water, or by the sword. Satisfied with this
 assurance, they immediately began to show how
 well they understood the value of their powers,
 they conquered the whole earth, and then
 dethroned Indra, king of heaven. He immedi-
 ately carried his complaint to Brahmá, who
 very coolly answered that he could take no part

against those upon whom he had bestowed a blessing; but that perhaps Vishnú would. This latter deity kindly undertook to settle the business, and restore Indra to his kingdom. To effect that purpose he assumed a mixed form, half man and half lion; he concealed himself in a column in Hiranya-kas'ipu's palace, and, when that gigantic monster struck the column in a fit of rage and profaneness, out started Nerasing'ha, seized the giant by his thigh, and ripped him up in an instant. This was certainly the action neither of fire, water, nor the sword; it was certainly not done by any ordinary being; neither was it done by day or night, for it was in the evening, and it was also under the eaves, and consequently between earth and heaven. Thus was Brahma's promise fulfilled. How the other worthy Hiranyáksha, or Gold-eye, was killed we are not told; but Vishnú consoled Pralháda, Hyranya-kas'ipu's pious son, by assuring him that his father would ascend to heaven.

The fifth, or Vámana incarnation, was occasioned by the same family. Pralhád'ha had a very audacious son, named Bali, who daringly made offerings to himself, and performed the as'wa-méd'ha, or sacrifice of a horse so often, that scarcely any thing could be refused to him, and he demanded the throne of heaven. Vishnú, having been applied to for relief against this troublesome giant, conveyed himself into the body of Aditi, the wife of Kas'ypa, the grandfather of the giants, and was born a dwarf—Vámana. His diminutive size charmed the tyrant Bali, who, to gratify him, promised to give whatever he should ask. He modestly demanded as much land as could be measured, by three steps: and, placing one foot on earth and another on heaven, out started a third from his belly, for which he demanded a resting-place; the king's head was the only one that could be found, and to make up matters with the god, whose power was now indisputable, Bali consented to go down to Patala, or hell, on a promise of Vishnú's protection. Thus did a dwarf repress the turbulence of a giant.

In the sixth, or Parasú-Ramá Avatár, Vishnú came into the world, as the son of Jamadagni, a descendant of the sage B'hrigu, in order to chastise the military caste, or Kshatriyas, whose insolence and disorder had become insufferable. One of them, a king, named Arjuna, took a fancy to a marvellous cow, named Káma-d'hénu, the property of Jamadagni, and attacking her possessor with a large army, routed and slew him. Ráma, the son of the luckless sage, determined to avenge his father's death, and going to Kailása (Olympus), knocked down Siva's porters, who refused admittance to him, presented himself to the god, and received from him a paras'u, or weapon with which he slew Arjuna. These incarnations all took place in the Satya Yuga, or Golden Age: the remainder are more modern.

The seventh, or Ráma-chandra Avatár, was Vishnú's descent for the purpose of subduing another giant Ravana, who reigned in Lankà, or Ceylon, and carried off Sità, the wife of Ramá, in his absence from home. Their contests and the final victory of Ráma are the subject of the celebrated epic poem called the Ramáyana.

VOL. III.

Pralamba, and other troublesome giants, who, it appears, were not confined to the golden age of the Hindoo mythology, made an eighth incarnation requisite, and Vishnú again descended in the form of Bala-Ráma. This took place in the Dwápar, or Brazen Age, and brings us nearer to the period of something like genuine history.

Budd'ha, the ninth, overcame the giants, his adversaries, by a very singular artifice; he produced, by his preaching, an universal scepticism, so that the gods, no longer compelled to grant prayers, had no difficulty in ridding the world of its scourges, these all-powerful giants.

The Kalki, or tenth Avatár, is yet to come! He will be the son of a Bráhma, and be born in the city of Samb'hala at the close of the Kali Yuga, or Iron age. He will appear, say the Bráhmans, mounted, like a crowned conqueror, on a white steed, with a scymitar blazing like a comet, to mow down all his foes. Plates of the incarnations of Vishnú from Indian drawings, were first given by Athanasius Kircher, in his *China Illustrata*, in 1667. They are to be found also in Baldæus (Churchill's collection), whence they were copied in Mr. Maurice's *Indian Antiquities*: which see.—*Ward's View of Hindoo Literature, &c.*

AVAUNCHERS, among hunters, the second branches of a deer's horns.

AVAUNT. Fr. *avant*, a word of abhorrence, by which any one is driven away.

O, he is bold, and blushes not at death;

Avant, thou hateful villain, get thee gone!

Shakespeare.

AVAUX, a town of Champagne, in France, with 1500 inhabitants, belonging to the department of the Ardennes, arrondissement of Rhétel. It is seated on the Aisne, not far from Rheims, and formerly belonged to the family of de Memes, from whom sprung the celebrated diplomatist Claudius comte d'Avaux, ambassador of France at the treaty of Westphalia.

AUB, or Auw, a balliwick and town of Franconia, on the Gollach, between Uffenheim and Ochsenfurt. It had, in 1804, about 160 houses, and 1120 inhabitants, and belonged to the district of Rottingen, in the principality of Wurtzburg, but was united to Bavaria in 1815. The hospital is well endowed. It is seventeen miles south of Wurtzburg. Long. 10° 10' E., lat. 49° 37' N.

AUBAINE, in the ci-devant customs of France, was a right vested in the king of being heir to all foreigners that died within his dominions. By this right the French king claimed the whole inheritance of foreigners, notwithstanding any testament the deceased could make. But an ambassador was not subjected to it; and the Swiss, Savoyards, Scots, and Portuguese, were also exempted.

AUBE, a department of France, so named from the river bounded on the north by that of Marne; on the east by Upper Marne; on the south by those of the Cote d'Or and Yonne; and on the west by that of Seine and Marne. Its chief town is Troyes.

AUBE, a river of France, which rises in the department of Upper Marne, and, running through

that of Aube, passes by Bar-sur-Aube and Arcis, and falls into the Seine, near Nogent.

AUBENAS, a town of France, in the Lower Vivarais, in Languedoc, now included in the department of the Ardeche, arrondissement of Privas. It was for some time the capital of an arrondissement, but is now only the head of a canton. The population is about 3315. Aubenas is a manufacturing place of some consequence, containing silk-mills and extensive cloth-works. The twisted silk, called organzin, is wrought here by a mill, constructed by the ingenious Vaucanson; the average quantity manufactured in a year being 550 cwt. Here also are made handkerchiefs, neckcloths, chintzes, and stuffs, partly consumed in the country, and partly exported to the Levant. The raw material is brought chiefly from Spain. The cloths dyed here are also in great repute. In the neighbourhood is a famous medicinal spring, and mines of coal. It lies on the Ardeche, five leagues S. W. of Privas, and 135 S. E. of Paris.

AUBERT (Peter), an eminent French lawyer, born at Lyons in 1642. He appeared very early in the world as an author, by the publication of a romance, called *Récit d'Isle d'Amour*. He filled several important stations in the city of Lyons, and established an extensive public library. In 1710 he published two volumes of Cases, and, in 1723, a new edition of Richelet's Dictionary, three volumes, folio.

AUBERTIN (Edmund), a French Protestant divine,—was born in 1595, and in 1631 was chosen minister of the reformed church at Paris. In 1633 he published a work on the Eucharist of the ancient church, which was attacked by Arnauld and other Catholic writers. He died at Paris in 1652.

AUBERY (Anthony), a French lawyer, and historical writer, born in 1617. He was very much given to study, taking no pleasure in the bustle of public business, but preferring a retired life. The following are the principal fruits of his labours: 1. *The History of the Cardinals*, five volumes, 4to. 1612. 2. *Memoirs of the Cardinal de Richelieu*, two volumes, folio, 1660; in which the character of the cardinal is more respected than truth, which is sometimes sacrificed to his praise. 3. *The History of Cardinal Mazarin*, four volumes, 12mo. 1751. 4. *On the Pre-eminence of the kings of France*, 4to. 1649. 5. *A Treatise on the Pretensions of the king of France to the Empire*, 4to. 1667. He died in 1695.

AUBRY (John), a French physician of the seventeenth century. He was author of an *Apology for Physic*, in Latin, 8vo. printed at Paris in 1608, and an *Antidote to Love*, in French, 12mo. 1559.

AUBRY (Louis de Maurier), a French writer. In 1682 he published *Memoirs for a History of Holland*, two volumes, 12mo. He died in 1687, leaving *Memoirs of Hamburg, Lubeck, Holstein, Denmark, and Sweden*, which were published at Amsterdam, in 1737.

AUBESPINE (Claude de l'), baron of Chateau-Neuf. He was a descendant of a noble family at Châtinais, and filled the office of secretary of state under several of the kings of France. He died in 1567.

AUBESPINE (Charles de l'), marquis of Chateau-Neuf. He was chancellor of France, but was imprisoned ten years. After his liberation he was taken into favor by Henry IV. He died in 1653.

AUBESPINE (Gabriel de l'), was of the same family with the above. He became bishop of Orleans, in which station he showed himself a man of great learning. He died in 1630, aged fifty-two.

AUBESPINE (Magdalen de l'), a celebrated French lady. She was the wife of de Neuville, seigneur de Villeroi, and author of several excellent pieces in prose and verse. She died in 1596.

AUBIER, or **AUBOUR**, the French name for that soft whitish substance which lies round a tree between the bark and the solid wood. Mr. Barkley thinks it performs the office of veins. It may be considered as a third bark, whose fibres are less compact than those of the others, and is properly the fat of the tree. It hardens gradually, and becomes imperceptibly a part of the woody substance. There are few trees without some aubier, which is more or less thick according to the situation in which the trees are planted, for the more they are exposed to the rays of the sun the less aubier will be found in them. In the oak it is seldom above an inch, or an inch and a half thick. When a tree is cut down, or dies in the ground, the aubier remains always of the same consistency without being turned into solid wood. It is liable to rot, and therefore merchants ought to take care that as little aubier is left on their wood as possible.

AUBIGNAN, a town of France, in the Venaissin, with the title of marquise, and 1320 inhabitants, now included in the department of Vaucluse, arrondissement of Orange. It is famed for its oil. Five leagues and a half N. E. from Avignon.

AUBIGNE (D' Theodore Agrippa), an illustrious French author, was born in 1550. He made such an early progress in letters, that he is said to have translated Plato's *Crito*, from the Greek into French, when he was only eight years old. His father dying when he was thirteen, he attached himself to the cause of Henry IV. under whom he fought, and who made him gentleman of his bedchamber. He soon became a favorite with Henry, who raised him to several other high offices; but he at length lost his favor, partly by refusing to comply with his passions, and partly by a democratic kind of inflexibility. Quitting France, he took refuge in Geneva, where he was highly honored, and spent the remainder of his days in writing different works. His chief production is his *Histoire Universelle*, from 1550 to 1601; with a short *Account of the Death of Henry IV.* three volumes, folio. The first volume was scarcely published when the parliament of Paris condemned it to be burnt, as 'a work wherein kings are treated not only with little respect, but even outraged!' He died at Geneva, in 1630, aged eighty.

AUBIGNE, or **AUBIGNY**, a small town of France, in the department of Cher, seated on the Nerre, in a fine plain, twenty-four miles north of Bourges.

It is surrounded with strong walls, wide ditches, and high counterscarps. The castle is within the town, and is very handsome. Long. 2° 28' E., lat. 47° 31' N.

AUBIGNY, a ci-devant dukedom in France, belonging to the duke of Richmond in England, as descendant of the duchess of Portland, the favorite mistress of Charles II., at whose solicitation it was given her. It was confirmed to the duke of Richmond and registered in the Parliament of Paris in 1777, but abolished with other French titles in 1790.

AUBIN, in horsemanship, a broken kind of gait, between an amble and a gallop,—accounted a defect.

AUBIN (St.), sometimes called Hodiere, a market town, situated on a bay of the same name, in the island of Jersey, three miles from St. Hilier's. The port is defended by a pier, which runs out into the sea, in the same manner as that at Guernsey. The town is well built, and much frequented by merchants. The parish church being at some distance, there is here a chapel of ease. Market on Mondays. Latitude 49° 7', N. long. 2° 15' W.

AUBLETIA, in botany, a genus of the class and order polyandria monogynia. The essential characters are, calyx five-leaved, corolla, five-petalled, capsule many celled, echinate, with many seeds in each cell. There are three species, all trees, and natives of South America.

AUBONNE, a district or bailiage of Switzerland, in the canton of Bern, and territory of Vaud, which contains several villages, mostly at the foot of mount Jura.

AUBONNE, a rapid river of Switzerland, which runs through the above district, and falls into the lake of Geneva. In mount Jura there is a very deep cave, which is a natural and perpetual ice-house. At the bottom is heard a great noise, like that of a subterraneous river, which is supposed to be that of the Aubonne, because it first appears with several sources, about a hundred paces from the foot of that mountain.

AUBONNE, a town of Switzerland, in the above district, situated near the river, seven miles north of the lake of Geneva, upon an eminence which has a gentle declivity, at the foot of which runs the river, with an impetuous torrent. It is built in the form of an amphitheatre; on the upper part of which stands a castle with a court, and a portico supported by pillars of a single stone each. The castle stands high, and there is a most delightful prospect, not only of the town and neighbouring fields, but of the whole lake of Geneva and the land that surrounds it. Aubonne is situated eighteen miles W. of Lausanne. Long. 6° 15' E., lat. 46° 30' N.

AUBREY (John), F. R. S. a famous English antiquary, born at Eston-Piers, in Wiltshire, in 1626, and educated at Trinity college, Oxford. In 1646 he was entered of the middle Temple, but quitted the study of the law on account of some embarrassments in his private affairs. He contracted an intimacy with several learned men, and was one of the first members of the Royal Society. He made the history and antiquities of England his peculiar study; and contributed considerable assistance to the famous Monasticon

Anglicanum. He succeeded to several good estates, but law-suits and other misfortunes consumed them all, so that he was reduced to absolute want. In this extremity he found a valuable benefactress in lady Long, of Dracot, who gave him an apartment in her house, and supported him till his death, which happened about A. D. 1700. He was a good Latin poet, and an excellent naturalist, but somewhat credulous, and tainted with superstition. He wrote, 1. Miscellanies. 2. A Perambulation of the county of Surry, in five volumes, 8vo. 3. The Life of Mr. Hobbes of Malmsbury. 4. Monumenta Britannica, or a Discourse concerning Stonehenge, and Roll-Rich Stones in Oxfordshire. 5. Architectonica Sacra. 6. The Natural History of Wiltshire. 7. Universal Education, and several other works still in MS.

AUBRIOT (Hugo), a French reformer, from whom the appellation Hugonots. He was treasurer of the finances, and mayor of Paris; and under his magistracy the Bastile was built, in 1369. Soon after he was accused of heresy, and sentenced to confinement between two walls, from which the Maillotins, a set of insurgents, released him, in 1381. He however left them, and retired into Burgundy, where he died the following year.

AUBUSSON (Peter d'), grand master of the knights of Rhodes, was born in La Marche, in 1423. Having entered into the order of St. John of Jerusalem, he was elected grand master, in 1476; and, in 1480, when the Turks made an attack upon the island, it was by his vigorous conduct they were repulsed. He obtained a cardinal's hat by very dishonorable means—the delivering up to the pope prince Zizim, brother of Bajazet, who had taken refuge in Rhodes, from the vengeance of the sultan. He died in 1503.

AUBURN. Sometimes written *ABRON*, which it is suggested may be the past participle of *to bren*, or *brin*, to burn; *quasi*, browned. Others contend for *alburn*, from whiteness, regarding it as a color inclining to white.

His faire *auberne* haire had nothing upon it but white ribbin. *Pembroke's Arcadia.*

Not wanten white, but such a manly colour

Next to an *abron*, tough, and nimble set;

Which shows an active soul.

Beaumont and Fletcher. The Two Noble Kinsmen.

These curious locks so aptly twin'd,

Whose every hair a soul doth bind,

Will change their *auburn* hue and grow

White and cold as winter snow.

Carew. Persuasions to Love.

Close to her side, in radiant arms, a youth,

Who like the brother of the Graces moves,

His head uncas'd, discovers *auburn* locks

Curl'd thick, not flowing.

Glover's Leonidas, book ii.

And not a year but pilfers as he goes

Some youthful grace that age would gladly keep,

A tooth, or *auburn* lock. *Cowper's Poems.*

AUBUSSON, a small town of France, in the department of Creuse, thirty-seven miles north-east of Limoges. Its situation is very irregular, on the river Creuse, in a bottom surrounded with rocks and mountains.

AUCAGUREL, the capital of the kingdom of Adel, in Africa, seated on a mountain. Long. 44° 25' E., lat. 9° 10' N.

AUCH, a town of France, in the department of the Gers. It has a beautiful cathedral, and is sixteen leagues west of Toulouse.

AUCH, or ACH, in the Gaelic, signifies a field of some extent, generally arable and horizontal. In composition, Auchan, Auchin, or, as it ought rather to be spelt, Auch-an, signifies the field of, the particle an, in Gaelic, being always the sign of the genitive, when placed between two substantives; although when prefixed to one substantive, it implies only the definite article the.

AUCHABER, or ACHABER, a hill in Aberdeenshire, in the parish of Forgue, on the south-east declivity, of which there are the remains of an elegant circular Roman redoubt.

AUCHINLECK, in Gaelic, a field of rock; a parish of Scotland, in Ayrshire, eighteen miles in length, and two in breadth; memorable for being the birth-place, as well as the property, of the late James Boswell, Esq. The soil, except upon the rocks and banks of the rivers, is poor; but this is compensated by its abounding in excellent coals, free-stone, a black stone, which is fire-proof, used for building ovens, and other minerals. It has also a lead mine, which some think rather a silver mine, but it has never been wrought; and two mineral wells. It has the ruins of an ancient castle, of whose age there is no tradition; and is ornamented with an elegant mansion-house, built by the late lord Auchinleck.

AUCHINLILLY LASS SPURT, a cataract in the parish of Fintry, in Stirlingshire, over which the Carron rushes in its course from Carron bog to the cascade of Falkirk.

AUCHLOSSEN, Loch of, a lake in the parish of Lumphanan, in Aberdeenshire, nearly a mile in length, and above half a mile broad at the south end. It produces eels and pikes; some of the latter six feet long, and twenty-five pounds in weight. It often overflows its banks in summer.

AUCHMUTY (Sir Samuel), lieutenant-general, G. C. B. and colonel of the 78th regiment of foot, entered the army in 1776, as a volunteer in the 45th regiment; and served with Sir W. Howe in North America, the three following campaigns. In 1783 he held a company in the 75th foot in the East Indies, and was present at the first siege of Seringapatam, under lord Cornwallis. In 1801 he was appointed adjutant-general to the expedition against Egypt. He was ordered out to South America in 1806, where he assumed the command of the troops, with the rank of brigadier-general; and in February, 1807, carried Monte Video by assault, after a most determined resistance; for which services he received the thanks of parliament. In 1809 he was appointed commander-in-chief of the Carnatic; and in 1811 reduced the settlements of Java and Batavia under the dominion of Great Britain, for which he again obtained the thanks of both houses. On his return to Europe, Sir Samuel succeeded Sir D. Baird, as chief of the staff in Ireland. His death, occasioned by apoplexy, took place August 11, 1822, in the sixty-sixth year of his age. His remains, after lying in state at Kilmainham hospital, were in-

terred in the royal vault in Christ Church Cathedral, Dublin.

AUCHTER, a Gaelic word, signifying high, or upper, which in composition makes part of many ancient names of places.

AUCHTERMUCHTY, a town of Scotland, in Fifeshire, which was constituted a royal burgh by James IV. confirmed by James VI. and still enjoys all the privileges, except that of electing a representative in parliament. It has three bailies, fourteen counsellors, a treasurer and clerk; and four fairs, viz. on 21st August, first Tuesday of November and April, and 13th July, which last is one of the most considerable in Fifeshire, for horses, cattle, &c. The church was built in 1780, and an elegant manse in 1792. The chief manufacture is white and brown linens.

AUCKLAND, Bishop, a market town in the county palatine of Durham, with a population of near 2000. Here is the palace of the Bishop of Durham, began in 1283, by bishop Beck, and is a noble, though irregular, structure. It is 257 miles north-west of London, and ten miles and a half south-west of Durham.

AUCKLAND (William Eden, lord), was the third son of Sir Robert Eden, bart. of West Auckland, in the county of Durham. Educated at Eton and Oxford, he was called to the bar by the society of the Middle Temple in 1769, and accompanied the earl of Carlisle, in 1778, to negotiate terms with the revolted colonies of America. He was chief secretary during the same nobleman's viceroyalty in Ireland. In 1785 he was sent ambassador extraordinary to negotiate a commercial treaty with France; and in 1788 performed a similar service with Spain. In 1789 he concluded, at the Hague, a treaty between Great Britain, the emperor, and the king of Prussia, in settlement of the affairs of the Netherlands; and the same year he was created baron Auckland, of the kingdom of Ireland. In 1793 he was advanced to the English peerage by the same title. Lord Auckland was considered an able diplomatist, and is the author of the following works: The Principles of Penal Law, 8vo. 1771; Five Letters to the earl of Carlisle, 8vo.; On the Population of England, in Answer to Dr. Price, 8vo.; View of the Treaty of Commerce with France, 8vo.; The History of New Holland, 8vo.; Remarks on the War, 8vo. 1795; and various speeches in the House of Lords. He died in 1814.

AUCTION, } Lat. *augeo, auctum*. Gr.
AUCTIONARY, } *Αυξω*, increase; *auctio*, an in-
AUCTIONEER, } creasing. Auction is a selling to those who will give the highest price for the article offered. After successive biddings at a price constantly advancing, the last bidder is the buyer.

And much more honest, to be hir'd, and stand
With auctionary hammer in thy hand;
Provoking, to give more, and knocking thrice,
For the old household stuff, or picture's price.

Dryden's Juvenal.

Estates are landscapes, gaz'd upon awhile,
Then advertis'd, and auctioneer'd away.

Cowper's Poems. The Task, book iii.

AUCTION, in old medical writings, the nourishment of an animal body, whereby it is increased in size.

AUCTION, in Roman antiquity, was originally a kind of sale, performed by the public crier sub hasta, i. e. under a spear stuck up on the occasion, and by a magistrate, who delivered the goods. It was termed *auctio*, q. d. increase, because the goods were sold to him, qui plurimum rem auget, who bid most for them. The auctioneer was called *Auctor*; and the term *auctoritas* denoted the right of property which the sale vested in the purchaser. A spear being set up in the forum as the sign of an auction, the phrase sub hasta venire; (literally, to be sold under the spear) denoted a sale by auction.

The civil law, according to Huber, *Prælectiones*, xviii. 2. 7. held private biddings, by or on behalf of the seller, to be fraudulent: and this principle was adopted by the courts of law in this country, in the days of Lord Mansfield, whose inclination to adopt the maxims of the civil code is well known; but latterly the legislature seems to recognise the practice, by exempting such private biddings from the duty imposed on sales by auction. A sale, however, cannot be supported where the purchaser was the only real bidder, and public notice was not given of the owner's intention to bid; but that public notice is not essential to the validity of a sale, if there be a contest between one or more real bidders. (See Sugden's Law of Vendors). In a Dutch auction, the auctioneer commences by naming a high price, and gradually reduces it, until some person closes with his offer.

AUCTORATI, in Roman antiquity, persons who entered the lists as gladiators, and received wages, or hired themselves to perform in the public games.

AUCTORATI MILITES, soldiers bound by oath, and the receipt of wages, to serve in war. They stood opposed to the *exauctorati*, who were disbanded. The payment they received for their service was denominated *auctoramentum*.

AUDA'CIOUS, } Lat. *audax*, daring; from
AUDA'CIOUSLY, } *audeo*, I dare. These words
AUDA'CIOUSNESS, } describe that bold enter-
AUDA'CIOUSLY, } prising incautious spirit,
 which, without deliberation, undertakes to try to
 vanquish.

Your reasons at dinner have been sharp and sententious; pleasant without scurrility, witty without affectation, *audacious* without impudency.

Shakspeare. Love's Labour Lost.

Excusing, cavilling upon mandates and directions, is a kind of shaking off the yoke and assay of disobedience; especially, if in those disputing they which are for the direction speak fearfully and tenderly, and those that are against it, *audaciously*.

Lord Bacon's Essays.

Annibal took his losse and damage nothing neere the heart, but rather made full reckning, that he had caught (as it were) with a bait, and fleshed the *audaciousness* of the foolchastie consull, and of the souldiours especially.

Holland's Livy.

As when the wolf has torn a bullock's hide,

At unawares, or ranch'd a shepherd's side;

Conscious of his *audacious* deed he flies,

And claps his quiv ring tail between his thighs.

Dryden's Virgil. Æn. 11.

As knowledge without justice ought to be called cunning rather than wisdom, so a mind prepared to

meet danger, if excited by its own eagerness, and not the public good, deserves the name of *audacity* rather than of fortitude.

Steele.

AUDE, a department of France, bounded by that of Arriège on the west, Upper Garonne on the north-west, Tarn on the north, Herault on the north-east, the Mediterranean on the east, and the eastern Pyrenees on the south. It is named from the river.

AUDE, a river in France, which rises in the Cerdagne among the Pyrenees, and, running north by Alet, visits Carcassone, and, directing its course by Quillan and Limouse, falls into the Mediterranean, a little to the north-east of Narbonne. The Romans dug up gold from its banks and channel.

AUDEANISM, the same with anthropomorphism. See **ANTHROPOMORPHITE**.

AUDEBERT, Germain, a counsellor of Orleans, on whom the senate of Venice conferred the order of knight of St. Mark, for a panegyric in verse, upon the republic, written by him while at that city. Henry II. honored him with a patent of nobility. He died in 1598; and his poems were collected and published in 1602.

AUDEBERT, John Baptist, a French naturalist, and a celebrated engraver of natural history, was born at Rochefort, in 1759. So much did he excel in the just and elegant representation of animals, that his productions are accounted among the most valuable in the line. His first piece was *L'Hist. Nat. des Singes des Makis et des Galeopithèques*; a folio volume, published in 1800. This work drew the attention of the professors of the museum of natural history at Paris, who recommended it and the author in honorable terms to the minister of the interior. He did not live to enjoy the fruits of his labors: but died in 1800, while engaged in other works of equal splendor.

AUDEUS, or **AUDIUS**, the chief of the Audeans, obtained the name of a heretic, and the punishment of banishment, for celebrating easter in the manner of the Jews, and attributing a human form to the Deity. He died in the country of the Goths, about A. D. 370.

AUDIENISM, the system of Audius and his followers; particularly as to the belief of the human figure of the Deity. See **ANTHROPOMORPHITES**.

AU'DIBLE, *n.* & *adj.* } Lat. *audio*, I hear;
AU'DIBLY, } that which may be
AU'DIENCE, } heard. Loud enough
AU'DIENT, } to be heard; sounding.

But when this lady comen was
 To th' emperour, in his presence,
 She said aloud in *audience*.

Gower. Con. A. book ii.

Visibles are swiffler carried to the sense than *audibles*; as appeareth in thunder and lightning, flame and report of a piece.

Bacon's Works, vol. i.

Therefore the Omnipotent

Eternal Father (for where is not he Present), thus to his Son *audibly* spake.

Milton. Paradise Lost, b. vii.

Don Quixote did prosecute his discourse, in such sort, and with so pleasing terms, as he had almost induced his *audients* to esteem him to be at that time at least exempt from his frenzie.

Shelton's Trans. of Don Quixote.

AUDIENCE COURT; a court belonging to the archbishop of Canterbury, of equal authority with the arches court, though inferior both in dignity and antiquity. The original of this court was, because the archbishop of Canterbury heard several causes extrajudicially at home in his own palace; which he usually committed to be discussed by men learned in the civil and canon laws, whom he called his auditors; and so in time it became the power of the man, who is called *causarum negotiorumque audientiæ Cantuariensis auditor, seu officialis*. Cowel.

AUDIENSCE COURTS are chiefly concerned in deciding differences arising upon elections, consecrations, institutions, marriages, &c.

AUDIENSCE is also the name of a court of justice established in the West Indies by the Spaniards, answering in effect to the parliament under the old government of France. These courts take in several provinces, called also audiences, from the names of the tribunal to which they belong.

AUDIENSCE OF AMBASSADORS: a ceremony observed in courts at the admission of ambassadors or public ministers to a hearing. In England, audience is given to ambassadors in the presence chamber: to envoys and residents, in a gallery, closet, or in any place where the king happens to be. Upon being admitted, as is the custom of all courts, they make three bows; after which they cover and sit down; but not before the king has covered and sat down, and has given them the sign to put on their hats. When the king does not wish to have them covered, and sit, he himself stands uncovered; which is taken as a slight. At Constantinople, ministers usually have audience of the prime vizier.

AUDIENDO ET TERMINANDO, a writ, or rather a commission to certain persons, when any insurrection or great riot is committed in any place, for the appeasing and punishment thereof.

AUDIENTES, or AUDITORES, in church history, an order of catechumens, consisting of those newly instructed in the mysteries of the Christian religion, and not yet admitted to baptism.

AUDIERET (John Baptist), an eminent French geographer born in 1657. He was employed on embassies to the courts of Mantua, Parma, and Modena; and was author of *Ancient and Modern Geography*, 3 vols. 4to. Paris, 1689. He died at Nancy, in 1733.

AUDIERER (Vital d'), a French nobleman, born at Menor, near Ville-franche de Rouergue, about 1595. Besides several other pieces, he wrote a treatise on Duels, printed at Paris in 1647; and *Poems* on different subjects, 2 vols. 8vo. 1644. He died in 1630.

AUDIRE, & n. } Lat. *audio*, I hear.
AUDIRE, & n. } To audit is to hear
AUDIRE, & n. & adj. } whatever may be said
AUDIRE, & n. } on the subject in hand
 with a view of passing a judgment; generally applied to the examination and passing of accounts by persons denominated auditors, but who are, perhaps, in these transactions, more properly, inspectors. Auditory applies to persons who hear, and sometimes to the place in which they are assembled.

In vain shall this be expected from our younger years; which the wise philosopher excludes from being meet *auditors*, much less judges of true morality.

Bp. Hall's Balm of Gilead.

Yet went she not; as, not with such discourse
 Delighted; or not capable her ear,
 Of what was high: such pleasure she reserv'd,
 Adam relating, she sole *auditress*. *Milton.*

Met in the church, I look upon you, as an *auditory*,
 fit to be waited on (as you are) by both universities.

South.

Several of this *auditory* were, perhaps, entire
 strangers to the person whose death we now lament.

Atterbury.

Foh! 'twas a bribe that left it; he has touch'd
 Corruption! whoso seeks an *audit* here
 Propitious, pays his tribute, game or fish,
 Wild fowl or ven'son; and his errand speaks.

Cowper's Poems.

Will make your very heart strings ake
 With loud and everlasting clam,
 And beat your *auditory* drum,
 Till you grow deaf, or they grow dumb.

Beattie. The Wolf and Shepherds.

AUDITA QUERELA, a writ which lies against him who has taken a recognizance in the nature of a statute-staple, or the like, and has asked, or obtained, execution from the mayor and bailiffs, or judges, before whom it was entered, &c. It is granted by the lord chancellor, upon view of the exception suggested, to the judges of either bench, willing them to grant summons to the sheriff of the county where the creditor is, for his appearance at a certain day before them. But the indulgence now shown by the courts in granting a summary relief upon motion, in cases of evident oppression, has almost rendered this writ useless, and driven it quite out of practice. A late learned judge, Ch. J. Eyre, i. B. and p. 428, states that the court will grant relief upon motion in all cases where a party would have been entitled to relief by *auditâ querelâ*. The legal student will find this subject clearly expounded in Mr. Serjeant Williams's notes to Saunders's Reports, in the case of Turner v. Davies, vol. ii. p. 137, d.

AUDITIONALIS SCHOLASTICUS, in writers of the middle age, an advocate who pleads causes for his clients in audiences.

AUDITORS OF THE REVENUE, or of the exchequer, officers who take the accounts of those who collect the revenue and taxes raised by parliament, the accounts of the sheriffs, escheators, collectors, tenants, customers, &c. The auditor of the exchequer, an office enjoyed for life, is one of considerable trust. He is to file the teller's bills, by which they charge themselves with all the monies received; and by warrant from the lord treasurer, or the commissioners of the treasury, he draws all orders to be signed by him or them, for issuing forth all monies, by virtue of privy seals, which are recorded in the clerk of the Pells' office, and entered and lodged in the auditor's office. He also, by warrant of the lord treasurer, or commissioners of the treasury, makes debentures to such as have fees, annuities or pensions, by letters patent from the king, out of the exchequer, and directs them for payment to the tellers. He daily receives the state of the account of each teller, and weekly

certificates the whole to the lords of the treasury. At Michaelmas and lady-day the auditor of the exchequer makes a declaration; that is, he delivers an abstract of all accounts and payments made in the preceding half year, one for the lords of the treasury, and the other for the chancellor of the exchequer. The office is holden for life.

AUDITORES, in church history, a branch of the Manichean sect, who were divided into electi and auditores; corresponding, according to some writers, to clergy and laity; and according to others, to the faithful and catechumens among the catholics. By the Manichean rule, a different course of life was prescribed to the elect from that of the auditors. The latter might eat flesh, drink wine, bathe, marry, traffic, possess estates, bear magistracy, and the like; all which things were forbidden to the elect. The auditors were obliged to maintain the elect, and knelt down to ask their blessing. Beausobre observes, that the elect were ecclesiastics, and in general such as made profession of observing certain counsels, called evangelic; such as the clergy and monks, and they were called the perfect by Theodoret. The auditors were the laity, and so denominated because they heard in the church, while others taught and instructed. See **AUDIENTES**.

AUDITORIUM, in the ancient churches, was that part where the audientes stood to hear and be instructed. The auditorium was the part now called *navis ecclesiæ*. See **NAVE**. In the primitive times, the church was so strict in keeping people together in that place, that the person who went from thence in sermon-time was ordered by the council of Carthage to be excommunicated.

AUDITORIUS MEATUS, the auditory passage or entrance of the ear, called also *aurium alveare*, on account of the wax collected in it.

AUDITORY, in ancient churches. See **AUDITORIUM**.

AUDITORY is also used for the bench whereon a magistrate, or judge, hears causes. At Rome, the magistrates had auditories, according to their dignity. Those of the superior officers were called tribunals; those of the inferior, *subsellia*. The *pedanei* had their auditories in the portico of the imperial palace. Those of the Hebrews, at the gates of cities. The judges appointed by the ancient lords distributed justice under an elm, which was usually planted before the manor-house, and served them for an auditory.

AUDITORY NERVES, the seventh pair, arising from the medulla oblongata, and distributed, the one to the ear, the other to the tongue, eye, &c.

AUDLEY (Edmund), the son of Lord Audley, bishop of Rochester and Hereford, under Henry VII., was a man of great learning and generosity. He gave £400 to Lincoln College, to purchase lands, and was also a benefactor to St. Mary's Church, Oxford. He died in 1524.

AUDLEY (James, Lord Audley), one of the English heroes who fought under Edward III. was born about 1314. In 1343 he was made governor of Berwick. In 1353 he reduced a great part of the country of Valois in France; and was present at the famous battle of Poitiers

in 1356; where, having obtained leave of Edward the Black Prince, to charge in front (in consequence of a vow he had made), he performed extraordinary feats of personal valor: but being at last dangerously wounded, was carried out of the field. In 1360 he again attended Edward III. to the wars in France; and after the peace, in 1361, was made constable of Gloucester Castle, governor of Aquitain, and seneschal of Poictou. He died April 1, 1386.

AUDLEY (Sir Thomas), descended of an ancient family in Essex, was born in 1488; and, having the advantage of an university education, was taken notice of by Henry VIII. and appointed speaker of the House of Commons in 1529. Having pleased the king in this station, he promoted him farther next year; and in 1532, appointed him Lord keeper of the Great Seal, on the resignation of the famous Sir Thomas More. In 1533 he made him Lord Chancellor, with suitable emoluments. In 1535 Audley sat in judgment, and pronounced sentence of death upon Sir Thomas More, as guilty of high treason, in refusing to acknowledge the king's supremacy in the church! Upon receiving sentence, Sir Thomas More said 'he had studied this subject for seven years, but could find no authority for a layman being head of the church;' to which Audley gave this decisive answer; 'Sir, will you be reckoned wiser, or of a better conscience, than all the bishops, the nobility, and the whole kingdom?' For these and the like services, Henry created Audley a baron and a knight of the garter in 1538. He died in 1544.

AUDLEY CASTLE, a fort of Ireland, built on a promontory in the county of Down, which has a prospect of the whole lake of Strangford.

AUDLEY ROAD, a part of Strangford Bay, on the west side, on the coast of Down in Ulster, where ships may lie in safety.

AUDRAN (Benoit, or Benedict), the second son of Germain Audran, was born at Lyons in 1661, where he learned the first principles of design and engraving under his father. But soon after going to Paris, his uncle Gerard Audran took him under his tuition; and he profited so greatly by his instructions, that though he never equalled the sublime style of his tutor, yet he deservedly acquired great reputation. Abbe Fontenai says, 'We admire in his works a share of those beauties which we find in the engravings of the illustrious Gerard.' He was appointed the king's engraver, received the royal pension, was made an academician, and admitted into the council, in 1715. He died unmarried at Louzouer, where he had an estate, in 1721. His manner was founded upon the bold clear style of his uncle. His outlines were firm and determined; his drawing correct; the beads of his figures are in general very expressive; and the other extremities well marked. His works, compared with those of his uncle, appear to want that mellowness and harmony so conspicuous in the latter; and the round dots with which he finishes his flesh upon the lights are often too predominant. In his most finished plates the mechanical part of the engraving is extremely neat, and managed with great taste. One of his neatest prints is that of Alexander sick, drinking

from the cup which his physician presents to him; a circular plate, from Le Sueur.

AUDRAN (Benoit), the second engraver of that name, the son of John Audran, and nephew to the former Benoit; was also established at Paris. A little attention will easily distinguish his works, which are vastly inferior to those of his uncle. One of the best of his plates is the descent from the cross, from a picture of Poussin.

AUDRAN (Carl), an eminent French engraver, brother, or cousin to Claude, was born at Paris in 1594. In his infancy he discovered much taste for the arts; and to perfect himself in engraving he went to Rome, where he produced several prints that did him great honor. At his return, he adopted that species of engraving which is performed with the graver only. He settled at Paris, where he died in 1674, unmarried. The abbé Marolles, who speaks of him with great praise, attributes 130 prints to him: amongst which, the annunciation, a middling sized plate, upright, from Annibale Caracci; and the assumption, in a circle, from Dominichino, are the most esteemed. In the early part of his life he marked his prints with C, for Carl, till his brother Claude published some plates with the same initial, when, for distinction sake, he used the letter K, or wrote his name Karl.

AUDRAN (Claude), a French engraver, the first of the celebrated artists of that name, was the son of Lewis Audran, an officer belonging to the wolf hunters in the reign of Henry IV. of France; and was born at Paris in 1592. Although he never made any great progress in the art, yet he had the honor to be the father of three great artists, Germain, Claude, and Gerard. The last of whom has immortalised the name of the family. He died at Lyons, in 1677.

AUDRAN (Claude), the second son to Claude, was born at Lyons in 1639, and went to Rome to study painting; where he succeeded so well, that at his return he was employed by Le Brun to assist him in the battles of Alexander, which he was then painting for Louis XIV. He was received into the Royal Academy in 1675, and died unmarried at Paris in 1684. His virtues (says abbé Fontenai) were as praise-worthy as his talents.

AUDRAN (Gerard), the most celebrated artist of his family, was the third son of Claude, and born at Lyons in 1640. He learned from his father the first principles of design and engraving at Lyons; and went to Paris, where his genius soon began to manifest itself. Le Brun employed him to engrave the battle of Constantine, and the triumph of that emperor; and for these works he obtained apartments at the Gobelins. At Rome he is said to have studied under Carlo Maratti, to perfect himself in drawing; and in that city he engraved several fine plates. M. Colbert was so struck with the beauty of Audran's works while he resided at Rome, that he persuaded Louis XIV. to recall him. On his return, he was appointed engraver to the king. In 1681 he was named counsellor of the Royal Academy; and died at Paris in 1703. He had been married, but left no male issue. The greatest excellency of this artist, above that of any other engraver, was, that though he drew

admirably himself, yet he contracted no manner of his own; but transcribed on copper simply, with great truth and spirit, the style of the masters whose pictures he copied. On viewing his prints, we lose sight of the engraver, and naturally say, it is Le Brun, Poussin, Mignard, or Le Sueur, &c. as we turn to the prints which he engraved from those masters. 'This sublime artist,' says the abbé Fontenai, 'far from conceiving that a servile arrangement of strokes, and the too frequently cold and affected clearness of the graver, were the great essentials of historical engraving, gave worth to his works by a bold mixture of free hatchings and dots, placed together apparently without order, but with an inimitable degree of taste; and has left to posterity most admirable examples of the style in which grand compositions ought to be treated. His greatest works, which have not a very flattering appearance to the ignorant eye, are the admiration of true connoisseurs and persons of fine taste. He acquired the most profound knowledge of the art, by the constant attention he bestowed upon the science of design, and the frequent use he made of painting from nature. He knew how to penetrate into the genius of the painter he copied from; often improved upon, and sometimes even surpassed him. Without exception, he was the most celebrated engraver that ever existed in the historical line. We have several subjects which he engraved from his own designs, that manifested as much taste as character and facility. But, in the battles of Alexander, he surpassed even the expectations of Le Brun himself.' These consist of three very large prints, length-ways, each consisting of four plates, which join together, from Le Brun, viz. The passage of the Granicus; The battle of Arbela; and Porus brought to Alexander, after his defeat. To this set are added two large prints, length-ways, on two plates each, also from Le Brun, viz. Alexander entering the tent of Darius, and the triumphal entry of Alexander into Babylon. The former was engraved by Gerard Edelinck, and the latter by Gerard Audran. Of all these plates, those impressions are most esteemed which have the name of Goyton the printer marked upon them.

AUDRAN (Germain), the eldest son of Claude, was born in 1631 at Lyons, where his parents then resided. Not content with the instructions of his father, he went to Paris, and perfected himself under his uncle Carl. Upon his return to Lyons, he published several prints which did him great honor. His merit was in such estimation, that he was made a member of the academy, and chosen a professor. He died at Lyons in 1710, and left behind him four sons, all artists; namely, Claude, Benoit, John, and Lewis.

AUDRAN (John), the third son of Germain Audran, was born at Lyons in 1667; and, after being instructed by his father, went to Paris to perfect himself in the art under his uncle Gerard. At the age of twenty he began to display his genius in a surprising manner; and his success was such, that in 1707 he obtained the title of engraver to the king, and had a pension allowed him, with apartments in the Gobelins;

and the following year he was made a member of the Royal Academy. He was eighty years of age before he quitted the graver; and near ninety when he died, at the apartments assigned him by the king. He left three sons, one of whom was also an engraver. 'The most masterly and best prints of this artist (in Mr. Strutt's opinion) are those which are not so pleasing to the eye at first sight. In these the etching constitutes a great part; and he has finished them in a bold rough style. The scientific hand of the master appears in them on examination. The drawing of the human figure, where it is shown, is correct. The heads are expressive and finely finished; the other extremities well marked. He has not, however, equalled his uncle. He wants that harmony in the effect; his lights are too much and too equally covered; and there is not sufficient difference between the style in which he has engraved his back grounds and his draperies. This observation refers to a fine print by him of Athaliah, and such as he engraved in that style. At other times he seems almost to have quitted the point, and substituted the graver. But here I think he has not so well succeeded. The effect is cold and silvery: see for example, the Andromache from Sylvestre. One of his best finished prints, in this neat style, seems to be Cupid and Psyche from Ant. Coyvel.'

AUDRAN (Lewis), the last son of Germain Audran, was born at Lyons in 1670; from whence he went to Paris in 1712, before he had produced any great number of prints. The most esteemed are his seven acts of mercy, on seven middling-sized plates, from Sebastian Bourdon.

AUDREY, or ETHELREDA, an Anglo-Saxon princess, wife of Egfrid, king of Northumberland. She turned abbess, and was canonized after her death.

AVE, } A corruption of the Latin
AVE MARY. } *Ave Maria*, Hail Mary! A reverential address used by Catholics to the Virgin Mary.

All his mind is bent on holiness,
To number *Ave Marias* on his beads. *Shakspeare.*

AVE MARY. In the Romish church, their chaplets and rosaries are divided into so many *ave-marias* and so many paternosters. It has been observed by Bingham and others, that among all the short prayers used by the ancients before their sermons, there is not the least mention of an *ave-mary*; and that its original can be carried no higher than the beginning of the fifteenth century, when Vincentius Ferrerius, who was a celebrated preacher, first used it before his discourses; from his example it obtained such authority, as not only to be prefixed to all the sermons of the Romish preachers, but to be joined with the Lord's Prayer in their breviary.

AVEIRO, a considerable town of Portugal, in Beira, seated near the head of a small gulf at the mouth of the Vouga; which forms a haven with a bar, over which vessels may pass that do not draw above eight or nine feet water. The city stands in a long plain, well watered, and very fertile. This plain is nine miles broad, from Porto to Coimbra; and is bounded on the east

by a chain of mountains called Sierra d'Alcoba, which reach from the one town to the other. Near this city salt is made in sufficient quantity to serve two or three provinces. It has a nunnery, where none are admitted but the daughters of the nobility. Many English are settled here, on account of the thriving trade in oil, salt, and fish, especially sardels. It lies thirty miles S. of Oporto. Long. 8° 30' W. lat. 40° 40' N.

AVEIRON, a department of France, bounded by that of Cantal on the north, by those of Lozere and Gard on the east, Hérault and Tarn on the south, and Lot on the west. It is named from the river.

AVEIRON, a river of France, which rises near Severac, and flowing by Rhodes and Villefranche, falls into the Garonne below Montauban.

AVEL, *avello*, Lat. to pull away.

The beaver in chase makes some divulsion of parts, yet are not these parts *avelled* to be termed testicles.

Brown.

AVELLA, a town of Campagni di Roma.

AVELLA. See AQUILA.

AVELLANA, in botany, *nux pontica*, filbert, a sort of nut, anciently so called, from Avellanum, a town of Campania, where they abounded. See AVELLINO. It is the *corylus avellana* of Linnaeus. Plin. l. 25, c. 23.

AVELLANA PURGATRIX, in the materia medica, the fruit of a species of ricinus.

AVELLANDA, in botany, a name given by the Spaniards to the roots of the Torsi, or sweet cyperus. These are esculent, and of a very delicious taste: they seem to have had the name from their likeness to the *avellana*, or hazel nut. Garcias, and some others, have thought that the *curcas* of Malabar was the same with the *avellanda* of Europe. But this does not seem to be the case; for the *curcas*, though of the same size and shape with the *avellanda*, has a hard coat like the common filbert.

AVELLANE, in heraldry, a cross, the quarters of which somewhat resemble a filbert-nut. Sylvanus Morgan says, that it is the cross which ensigns the sovereign's globe.

AVELLINO, a city of Italy, in the kingdom of Naples, with a bishop's see. It was almost ruined by an earthquake in 1694. It is, however, at present a pretty considerable place, extending a mile in length down the declivity of a hill, with ugly streets, but tolerable houses. The churches have nothing to recommend them, being crowded with monstrous ornaments in the barbarous style, which the Neapolitans seem to have borrowed from the Spaniards. The cathedral is a poor building, in a wretched situation, with little to attract the eye. The good catholics need not run to Naples to see the blood of St. Januarius; for they have a statue of St. Lawrence, with a phial of his blood; which, for eight days in August, entertains them here with a similar miraculous liquefaction. The only edifice of note is a public granary, of the Composite order, adorned with antique statues, and a very elegant bronze one of Charles II. of Spain, while a boy, cast by Cavalier Cosimo. The number of inhabitants amounts to 8000, some say 10,000. The bishop's revenue is

about 6000 ducats (£1125) a-year. The magistracy consists of a syndic and four eletti, all annual; which offices are engrossed by a certain number of families of distinction. Avellino has a considerable manufacture of cloth of various qualities and colors, but chiefly blue. Many wealthy merchants have a concern in this business. The second article of trade is maccheroni, and paste of many kinds, which, being of an excellent quality, are in high repute all over the country. Wooden chairs are also made and sold in great quantities. Avellino abounds with provisions of every sort; each street is supplied with wholesome water; but the wine is indifferent. The soil of this district, which consists chiefly of volcanic substances, produces little corn, but fruit in abundance, of which the apple is deservedly held in great esteem. The most profitable, however, of all its fruit-trees is the hazel. Nut-bushes cover the face of the valley, and in good years bring in a profit of 60,000 ducats (£11,250). The nuts are mostly of the large round species of filbert, which we call Spanish. These bushes were originally imported into Italy from Pontus, and known among the Romans by the appellation of *nux Pontica*, which, in process of time, was changed into that of *nux Avellana*, from the place where they had been propagated with the greatest success. The proprietors plant them in rows, and by dressing, form them into large bushes of many stems. Every year they refresh the roots with new earth, and prune off the straggling shoots with great attention. Between Avellino and Benevento is the Val di Garzano, better known in history by the name of Furca Condina, where the Romans were blocked up by the Samnites, and compelled to pass under the yoke, in the 433d year of Rome. Avellino is situated twenty-five miles N. E. of Naples. Long. 15° 20' E., lat. 41° 11' N.

AVELTON. See AITON.

AVEN, one of the Orkney Islands, better known by the name of Sunda.

AVEN, the Scriptural name of several ancient places; particularly, 1. of Bethel, by way of metaphor, Hos. x. 8. 2. of Heliopolis, a city of Egypt, Ezek. xxx. 17. See HELIOPOLIS. 3. of a plain in Syria, between Lebanon and Antilibanus, Amos, i. 5; supposed to be the same with Bad-beck, or the valley of Lebanon. See BANI-BECK.

AVENA, OATS, in botany, a genus of the diuymia order, and triandria class of plants; ranking in the natural method under the fourth order, gramina. The calyx has a double valve, and the awn on the back is contorted. There are thirteen species, of which the first six following are natives of Britain: viz. 1. *A. elatior*, the tall oat-grass. 2. *A. fatua*, the bearded oat-grass. 3. *A. flavescens*, the yellow oat-grass. 4. *A. nuda*, the naked oat. 5. *A. pratensis*, the meadow oat-grass. 6. *A. pubescens*, the rough oat-grass. 7. *A. sativa*, the common oat cultivated in our fields. It is remarkable, that the original native place of this plant is almost totally unknown. Anson says, that he observed it growing wild or spontaneously in the island of Juan Fernandez; but a vague observation from a single author is not to be depended on.

For the culture, see HUSBANDRY. Oats are an article of the *materia medica*. Gruels made from them have a kind of soft mucilaginous quality; by which they obtund acrimonious humors, and prove useful in inflammatory diseases, coughs, hoarseness, and exulcerations of the fauces.

AVENACEOUS, something belonging to, or partaking of the nature of oats.

AVENANT, agreeable; beautiful.—*Chauc.*

AVENCHE, an ancient city of Switzerland, in the canton of Bern, formerly the capital of all Switzerland, but now greatly decayed. It lies four miles S. W. of Murat, and fifteen W. of Bern. Long. 6° 52' E., lat. 46° 50' N.

AVENGE, *v. & n.* Fr. *venger*, Lat. *vim dicare* (*vim dicere*, Vos *dicere*), to repel force with force. To deal out the measure allowed by the Jewish law—'a tooth for a tooth,' &c.; to denounce vengeance, to retaliate an injury, to exact punishment not sanctioned by good laws, or the benign spirit of Christianity.

That he might work th' *avengement* for his shame,
On those two caitives, which had bred him blame.

Spenser

All those great battles (which thou boasts to win
Through strife and bloodshed, and *avengement*
Now praised) hereafter thou shalt repent.

Id. Faerie Queene

There that cruel queen *avengeress*
Heap on her new waves of weary wretchedness.

Id

This neglected, fear
Signal *avengance*; such as overtook
A miser.
I will *avenge* me of mine enemies.
They stood against their enemies, and were
avenged of their adversaries. *Philips.*
Isaiah.
Wisdom.
I will *avenge* the blood of Jezreel, upon the house
of Jehu. *Hosea.*

Till Jove, no longer patient, took his time,
T' *avenge* with thunder your audacious crime. *Dryden.*

The just *avenger* of his injured ancestors, the victorious Louis, was darting his thunder. *Id.*

But just disease to luxury succeeds;
And ev'ry death its own *avenger* breeds. *Pope.*
Too daring bard! whose unsuccessful pride
Th' immortal Muses in their art defied;
Th' *avenging* Muses of the light of day
Depriv'd his eyes, and snatch'd his voice away. *Id.*

The day shall come, that great *avenging* day,
When Troy's proud glories in the dust shall lay. *Id.*

Send thy arrows forth,
Strike, strike these tyrants and *avenge* my tears. *Cumberland.*

Little did I dream that I should have lived to see such disasters fallen upon her [the queen of France] in a nation of gallant men—in a nation of men of honour and of cavaliers. I thought ten thousand swords must have leaped out of their scabbards to *avenge* even a look that threatened her with insult.—But the age of chivalry is gone. *Burke.*

AUENHEIM, a town of Germany, in the circle of Suabia, near Offenbourg.

AVENIO an ancient town of Cavares, and one of the most opulent in Gallia Narbonensis; now called Avignon.

AVENPACE, a Spanish Moor of the twelfth century, who wrote a commentary upon Euclid; but having adopted the peripatetic philosophy, he attempted to explain the Koran, by the system of Aristotle, for which he was imprisoned at Corduba.

AVENS, in botany. See **CARYOPHYLLUS**.

AVENTINE (John), was born in 1466, in Abensperg, in Bavaria. He studied first at Ingolstadt, and afterwards at Paris. In 1503 he taught eloquence and poetry at Vienna; and in 1507 he taught Greek at Cracow, in Poland. In 1509 he read lectures on Cicero, at Ingolstadt; and in 1512 was appointed preceptor to the princes Lewis and Ernest, sons of Albert the Wise, duke of Bavaria; and travelled with the latter. After this he wrote the *Annals of Bavaria*, being encouraged by the dukes, who settled a pension on him. This work, which gained great reputation, was first published in 1534, by Jerome Ziegler, professor of poetry in the university of Ingolstadt; and afterwards at Basil, in 1580, by Nicolas Cisner. In 1529 he was forcibly taken out of his sister's house at Abensperg, and hurried to a jail; the true cause of which violence was never known; but it would probably have been carried to a much greater length, had not the duke of Bavaria interposed, and taken this learned man under his protection. Mr Bayle remarks, that the incurable melancholy, which from this time possessed Aventine, was so far from determining him to lead a life of celibacy, as he had done till he was sixty-four, that it induced him to think of marrying. He advised, however, with two of his friends, and consulted certain passages of the Bible relative to marriage. The result was, that it was best for him to marry; and having lost too much time, considering his age, he took the first woman he met with, who happened to be his own maid, ill-tempered, ugly, and extremely poor. He died in 1534, aged sixty-eight; leaving one daughter, who was then but two months old.

AVENTINE, or **AVENTINUS**, one of the seven hills on which Rome was built. It was also called *Murcius*, from Murcia, the goddess of sloth, who had a little chapel there; *Collis Dianæ*, from the temple of Diana; and *Remonius*, from Remus, who was buried there. It was taken within the compass of the city by Ancus Marcus. To the east it had the city walls; to the south the *Campus Figulinus*; to the west the Tiber; and to the north *Mons Palatinus*; in circuit two miles and a quarter.

AVENTURE, in our ancient writers, signify tournaments, or military exercises on horseback.

AVENUE. Fr. *venir*, *venir*; participles *venu*, *avenu*; Lat. *venire*, to come. Approach, opening, passage.

Good guards were set up, at all the *avenues* of the city; to keep all people, from going out.

Clarendon.

The regulations that are established at Thebes for keeping the *avenues* free from incumbrances, maintaining the aqueducts and rendering the baths convenient, for the cultivation of arts, and for the security of the public, are the most excellent that can be imagined.

Hawkesworth's Telemachus.

Truth is a strong hold, and diligence is laying siege to it: so that it must observe all the *avenues* and pass to it. *South.*

AVENUE, in fortification, an opening or inlet into a fort, bastion, or the like place, or the passes and ways to and from it.

AVENUE, in gardening, a walk planted on each side with trees, and leading to a house, garden-gate, wood, &c. and generally terminated by some distant object. All avenues that lead to a house ought to be at least as wide as the whole front of the house; if wider, they are better still; and avenues to woods and prospects ought not to be less than sixty feet wide. The trees should not be planted nearer to one another than thirty-five feet, especially if they are of a spreading kind; and the same ought to be the distance, if they are for a regular grove. The trees most proper for avenues with us, are the English elm, the lime, the horse-chestnut, the common chestnut, the beech, and the abele. The English elm will do in all grounds, except such as are very wet and shallow; and this is preferred to all other trees, because it will bear cutting, heading, or lopping, in any manner, better than many others. The rough or smooth Dutch elm is approved by some, because of its quick growth; this is a tree which will bear removing very well; it is also green almost as soon as any plant whatever in spring, and continues so as long as any. It makes an incomparable hedge, and is preferable to all other trees for lofty espaliers. The lime is valued for its natural growth and fine shade. The horse-chestnut is proper for all places that are not much exposed to rough winds. The common chestnut will do very well in a good soil; and rises to a considerable height when planted somewhat close; though, when it stands single, it is rather inclined to spread than to grow tall. The beech is a beautiful tree, and naturally grows well with us in its wild state; but it is less to be chosen for avenues, because it does not bear transplanting, and is very subject to miscarry. The abele is fit for any soil, and is the quickest grower of any forest-tree. It but seldom fails in transplanting; and succeeds very well in wet soils, in which the others are apt to fail. The oak is little used for avenues, because of its slow growth. The old method of planting avenues was with regular rows of trees, and this has been the practice till of late: but we have now a much more magnificent method, by setting the trees in clumps, making the opening much wider, and placing the clumps at about 300 feet distant from one another. In each of these clumps there should be planted either seven or nine trees; but this is only proper where the avenue is to be of some considerable length; for in short walks single rows of trees look better. The avenues made by clumps are fittest of all for parks. The trees in each clump should be planted about thirty feet asunder; and a trench should be thrown up round the whole clump, to prevent the deer from coming to the trees to bark them.

AVENZOAR, or **EBN-ZOAR**, Abu Merwan Abdalmalec, an eminent Arabian physician, who flourished about the end of the eleventh and beginning of the twelfth century. He was of noble

descent, and born at Seville, where he exercised his profession with great reputation. His grandfather and father were both physicians. The large estate he inherited, set him above practising for gain: he therefore took no fees from the poor, or from artificers, though he refused not the presents of princes and great men. His liberality was extended even to his enemies; for which reason he used to say, that they hated him not for any fault of his, but rather out of envy. Dr. Friend writes, that he lived to the age of 135; that he began to practise at forty, others say twenty, and had the advantage of a longer experience than almost any one ever had, for he enjoyed perfect health to his last hour. Avenzoar was contemporary with Averroes, who, according to Leo Africanus, heard the lectures of the former, and studied physic under him; this seems the more probable, because Averroes more than once gives Avenzoar a very high and deserved encomium, calling him 'admirable, glorious, the treasure of all knowledge, and the most supreme in physic, from the time of Galen to his own.' Avenzoar, notwithstanding, is by the generality of writers reckoned an empiric: but Dr. Friend observes, that this character suits him less than any of the Arabians. 'He was bred,' says he, 'in a physical family, his father and grandfather being both practitioners. He had a regular education; and not only learned what properly belongs to a physician, but every thing which relates to pharmacy or surgery.' Dr. Friend adds, 'that he was averse to quackery, rejected the idle superstition of astrologers; and throughout all his work professes himself so much of the dogmatical sect, that he has a great deal of reasoning about the causes and symptoms of distempers; and as in his theory he chiefly follows Galen, so he quotes him upon all occasions. Notwithstanding he is so Galenical, there are several particulars in him which seldom or never occur in other authors; and there are some cases which he relates from his own experience, which are worth perusing.' He wrote a book entitled *Tayassir fi'l-madawât w'altadbâr*, i. e. The method of preparing medicines and diet; which is much esteemed. This work was translated into Hebrew, A.D. 1280, and thence into Latin by Paravicinus, whose version has had several editions. The author added a supplement to it, under the title of *Jâmî*, or a collection. He also wrote a treatise *Filadwiyat w'al-hajhiyat*, i. e. Of Medicines and Food; wherein he treats of their qualities.

AVENZOAR, or EBEN-ZOAR, the son of the former, followed his father's profession; was in great favor with Almanzor, emperor of Morocco, and wrote several treatises on physic.

AVERT, *v* Fr. *avert*; Lat. *vercor*, to AVERTMENT, *v* fear with reverence. Compounded of *re pro valide*, greatly, and *vercor*, to think. To declare positively, solemnly.

The reason of the thing is clear;
Would Jove the naked truth *avert*.

Prior.

Then vainly the philosopher *averts*,
That reason guides our deeds, and instinct theirs;
How can we justly dif'rent causes frame,
When the effects entirely are the same? *Id.*

To avoid the oath, for *avertment* of the continuance of some estate, which is eigne, the party will sue a pardon. *Bacon.*

We may *aver*, though the power of God be infinite, the capacities of matter are within limits. *Bentley.*

That which Bucer and his associates *averred* above a hundred years ago, we still say and maintain; that which was the truth then, hath been so ever since, and shall be to all eternity. *Bp. Hall's Peace-maker.*

AVERA, in our ancient customs, a day's work of a ploughman, or other laborer, which the king's tenants in his demesne lands were obliged to pay the sheriff.

AVÉRAGE. Low Lat. *averagium*, to make or obtain a mean proportion by collecting the maxima and minima, or the highest and lowest prices.

AVERAGE, in commerce and navigation, is divided into three kinds. 1. The simple average, which consists in the extraordinary expences incurred for the ship alone, or for the merchandizes alone; such as the loss of anchors, masts, and rigging, occasioned by the common accidents at sea; the damages which happen to merchants by storm, prizes, shipwreck, wet, or rotting; all which must be paid and borne by the thing which suffered the damage. 2. The large and common average, being those expences incurred, and damages sustained, for the common security of the merchandizes and vessels, consequently to be borne by the ship and cargo, and to be regulated upon the whole. Of this number, are the goods or money given for the ransom of the ship and cargo, things thrown overboard for the safety of the ship, the expences of unloading, for entering into a river or harbour, and the provisions and hire of the sailors, when the ship is put under an embargo. 3. The small averages, which are the expences for towing and piloting the ship out of or into harbors, creeks, or rivers, one-third of which must be charged to the ship, and two-thirds to the cargo.

AVERAGE, in agriculture, a term used by the farmers in many parts of England, for the breaking of corn-fields.

AVÉRANI (Benedict), a native of Florence, who became Greek professor at Pisa, and wrote several critical tracts on classical authors. He died in 1707. After his death, his works were collected and printed at Florence, in 3 vols. 8vo 1717.

AVÉRANI (Joseph), brother to Benedict, was born in 1662. He became professor of law at Pisa, but was particularly devoted to the study of mathematics and natural philosophy. He died in 1738. Two volumes of his orations in the academy at Florence, and some other tracts, were printed after his death.

AUERBACH, a town of Upper Saxony, in Voigtland, fourteen miles south of Zwickau, and sixty W. S. W. of Dresden. On a high rock, about four miles from this place, is found a species of topaz, called kings-crown, which is said to excel the Spanish and Bohemian in hardness, and to equal the oriental in brilliancy.

AVER-CORN, in ancient writings, such corn as by custom is brought by the tenant's cart-riages to the lord's granary.

AVERDUPOIS. See VOIRDUPOIS.

AVERDY (Clement Charles de l'), an eminent French statesman, was born at Paris in 1720. He was counsellor of parliament, minister, and comptroller general of the finances under Louis XV. His reputation was so great, that his appointment gave general satisfaction to the people, but falling into some mismanagement, he requested his dismissal in 1764. He afterwards retired to his estate, and occupied himself in agricultural pursuits. Though he took no part in the revolution, but kept perfectly neutral, yet he was arrested and brought to the guillotine in 1793. He wrote, 1. *Suite des Experiences de Gambais sur le bleds noirs ou caries*, 8vo. 2. *Memoire sur le Procès criminal de Robert d'Artois, Comte de Beaumont pair de France*.

AVERIA, in our old law books, properly signify oxen or horses used for the plough; but in a general sense any cattle. When mention is made of one beast, they say 'quidam equus, vel quidam bos'; when of two or more they do not say equi or boves, but averia.

AVERIA, in commerce, a branch of the Spanish revenue, signifying a tax paid for convoys to guard the ships trading to America. It was first imposed when Sir Francis Drake made his voyage to the South Sea.

AVERIIS CAPTIS IN WITHERNAM, a writ for taking cattle when unlawfully distrained and driven out of the country, so that they cannot be relieved by the sheriff.

AVER-LAND, in our old writers, such lands as the tenants ploughed with their cattle, and manured cum averis suis, for the use of a monastery, or the lords of the soil.

AVERNAT, a sort of grape. See VINE.

AVERNI; from the privative *a*, and *ορνις*, a bird, as intimating that birds could not fly over them, but dropped down dead; among the ancient naturalists certain lakes and other places which infect the air with poisonous steams or vapors; called also mephites. Avernì are said to be common in Hungary, on account of its abundance of mines. The Grotto del Cani, in Italy, is a famous one. See AVERNUS.

AVERNO, the ancient Avernus, a lake of Lavoro in Naples, lying in a narrow valley, two miles long and one broad. It is 180 feet deep in some places, and the old walls standing upon its banks are supposed to be the ruins of a temple of Apollo. Vibus Sequester, and other ancient authors represented it as bottomless. Mr. Chambers says the modern Italians call it Lago di Tripergola. See the next article.

AVERNUS, a lake of Campania in Italy, near Baia, famous among the ancients for its poisonous qualities. It is described by Strabo as lying within the Lucrine bay, deep and darksome, surrounded with steep banks that hang threatening over it, and only accessible by one narrow passage. Black, aged groves stretched their boughs over the watery abyss, and with impenetrable foliage excluded almost every ray of wholesome light; mephitic vapors ascending from the hot bowels of the earth, being denied free passage to the upper atmosphere, floated along the surface in poisonous mist; and killed even the birds that

attempted to fly over it. These circumstances produced horrors fit for the gloomy votaries of the infernal deities. A colony of Cimmerians, as well suited to the rites as the place itself, cut dwellings in the bosom of the surrounding hills, and officiated as priests of Tartarus. Superstition, always delighted in dark ideas, early and eagerly seized upon this spot, and represented a cavern near it called the Sybil's cave, as the mouth of the infernal regions. Hither she led her trembling votaries to celebrate her dismal orgies; here she evoked the manes of departed heroes—here she offered sacrifices to the gods of hell, and attempted to dive into the secrets of futurity. Poets enlarged upon the popular theme, and painted its awful scenery with the strongest colors of their art. Homer brings Ulysses to Avernus, as to the mouth of the infernal abodes, and, in imitation of the Grecian bard, Virgil conducts his hero to the same ground. Whoever sailed thither, first did sacrifice, and endeavoured to propitiate the infernal powers, with the assistance of some priest, who attended upon the place, and directed the mystic performance. Within, a fountain of pure water broke out just over the sea, but which nobody tasted, as it was fancied to be a vein of the river Styx; near this fountain was the oracle; and the hot waters, frequent in these parts, were supposed to be branches of the burning Phlegethon. The holiness of these shades remained unimpeached for many years. Hannibal marched his army to offer incense at this altar; though it may be suspected he was led to this act of devotion rather by the hopes of surprising the garrison of Puteoli, than by his piety. After a long reign of undisturbed gloom and celebrity, a sudden glare of light was let in upon Avernus; the horrors were dispelled, and with them vanished the sanctity of the lake: the axe of Agrippa brought its forest to the ground, disturbed its sleepy waters with ships, and gave vent for all its malignant effluvia to escape. The virulence of these exhalations, as described by ancient authors, has appeared so very extraordinary, that modern writers, who know the place in a cleared state only, charge these accounts with exaggeration; but Swinburn thinks them entitled to more credit; for even now, he observes, the air is feverish and dangerous, as the jaundiced faces of the vine-dressers, who have succeeded the Sybils and the Cimmerians in the possession of the temple, most ruefully testify. Boccaccio relates, that during his residence at the Neapolitan court, the surface of this lake was suddenly covered with dead fish, black and singed, as if killed by some subaqueous eruption of fire. The changes of fortune in these lakes, is singular: in the splendid days of imperial Rome, the Lucrine was the chosen spot for the brilliant parties of pleasure of a voluptuous court: now, a slimy bed of rushes covers the scattered pools of this once beautiful sheet of water; while the once dusky Avernus is clear and serene, offering a most alluring surface and charming scene for similar amusements. Opposite to the temple is a cave usually styled the Sybil's grotto; but apparently more likely to have been the mouth of communication between Cuma and Avernus, than the abode of a pro-

phetess; especially as the Sybil is positively said by historians to have dwelt in a cavern under the Cumæan citadel. Mr. Eustace (Classical Tour) describes the Avernus as a circular sheet of water, about a mile and a half in circumference, and in many places nearly 190 feet deep; surrounded by ground low on the one side, on the other high, but not steep, in rich cultivation, and slightly wooded. On the southern bank stands a large and lofty octagonal building, vaulted, and of brick, with halls adjoining. This probably was the temple of Proserpine, or of Avernus itself. It is surrounded by vineyards. On the northern bank, under a steep, overhung with shrubs and brambles, is a subterraneous gallery, still called the Grotto della Sibilla. The first gallery runs under the Monte Grillo, in the direction of Baiæ. It opens into a second on the right, tending towards Cumæ; after some distance, a piece of water crosses it, called the Sybil's bath. The ground then rises rapidly, and all farther progress is stopped by the fallen walls. The situation and appearance of the cavern agree very closely with the description of Virgil. It branched out into several other galleries; and probably furnished him with much of the scenery in the sixth book. The Lago di Trippegola, as it is called at present, has lost all claim to its former appellation, since in winter it abounds in water-fowl. There can be no doubt that the lake is the crater of an exhausted volcano.

AVER-PENNY, *q. d.* AVERAGE PENNY, money contributed towards the king's sees; or money given to be freed thereof. See AVERAGE.

AVERHIOA, in botany, a genus of the decandria order, belonging to the pentagynia class of plants; ranking in the natural method under the fourth order, gymnales. The calyx has five leaves, the petals are five, opening at top; and the apple or fruit is pentagonous, and divided into five cells. There are three species, viz. 1. *A. acida*; 2. *A. Himbi*; and 3. *A. carambola*, called in Bengal the cumru or cumrunga. This plant is remarkable for possessing a power somewhat similar to those species of mimosa which are termed sensitive plants; its leaves on being touched moving very perceptibly. In the mimosa the moving faculty extends to the branches; but from the hardness of the wood this cannot be expected in the carambola. The leaves are alternately pinnated with an odd one; and their most common position in the day-time is horizontal, or on the sun's plane with the branch from which they come out. On being touched they move themselves downwards, frequently in so great a degree that the two opposite almost touch one another by their under sides, and the young ones sometimes either come into contact, or even pass each other; the whole of the leaves of one pinna move by striking the branch with the nail of the finger, or other hard substance; or each leaf can be moved singly, by making an impression that shall not extend beyond that leaf. In this way the leaves of one side of the pinna may be made to move one after another, whilst the opposite ones continue as they were; or they may be made to move alternately in any

order, by touching properly the leaf intended to be put in motion. But if the impression even on a single leaf be strong, all the leaves on that pinna, and sometimes on the neighbouring ones, will be affected by it. Notwithstanding this apparent sensibility of the leaf, however, large incisions may be made in it with a pair of sharp scissars, without occasioning the smallest motion; nay, it may even be cut almost entirely off, and the remaining part still continue unmoved, when by touching the wounded leaf with the finger or point of the scissars, motion will take place as if no injury had been offered. The reason is, that although the leaf be the ostensible part which moves, the petiolus is the seat both of sense and action: for although the leaf may be cut in pieces, or squeezed with great force, provided its direction be not changed without any motion being occasioned; yet if the impression on the leaf be made in such a way as to affect the petiolus, the motion will take place. When, therefore, it is wanted to confine the motion of a single leaf, either touch it so as only to affect its own petiolus, or without meddling with the leaf, touch the petiolus with any small pointed body, as a pin or knife. By compressing the universal petiolus near the place where a partial one comes out, the leaf moves in a few seconds in the same manner as if the partial petiolus had been touched. Whether the impression be made by puncture, percussion, or compression, the motion does not instantly follow; generally several seconds intervene, and then it is not with a jerk, but regular and gradual. Afterwards when the leaves return to their former situation, which is commonly in a quarter of an hour or less, it is in so slow a manner as to be almost imperceptible. On sticking a pin into the universal petiolus, as its origin, the leaf next it, which is always on the opposite side, next the second leaf on the outer, and so on. But this regular progression seldom continues throughout; for the leaves on the outer side of the pinna seem to be affected both more quickly, and with more energy, than those of the inner; so that the fourth leaf on the outer side frequently moves as soon as the third on the inner, and sometimes a leaf, especially on the inner side, does not move at all, whilst those above and below it are affected in their proper time. Sometimes the leaves at the extremity of the petiolus move sooner than several others, which were nearer the place where the pin was put in. On making a compression with a pair of pincers on the universal petiolus, between any two pair of leaves, those above the compressed part, or nearer the extremity of the petiolus, move sooner than those under it, or nearer the origin; and frequently the motion will extend upwards to the extreme leaf, whilst below it perhaps does not go farther than the nearest pair. If the leaves happen to be blown by the wind against one another, or against the branches, they are frequently put in motion; but when a branch is moved gently, either by the hand or the wind, without striking against any thing, no motion of the leaves take place. When left to themselves in the day-time, shaded from the sun, wind, rain, or any disturbing cause, the appearance of the leaves is different from that of other

pinuated plants. In the latter a great uniformity subsists in the respective position of the leaves on the pinna; but in the carambola, some will be seen on the horizontal plane, some raised above it, and others fallen under it; and in an hour or so, without any order or regularity which can be observed, all of them will have changed their respective positions. Cutting the bark of the branch down to the wood, and even separating it about the space of half an inch all around, so as to stop all communication by the vessels of the bark, does not for the first day affect the leaves, either in their position or their aptitude for motion. In a branch, which was cut through in such a manner as to leave it suspended only by a little of the bark no thicker than a thread, the leaves next day did not rise so high as the others; but they were green and fresh, and, on being touched, moved, but in a much less degree than formerly. After sun-set the leaves go to sleep, first moving down so as to touch one another by their under sides; they therefore perform more extensive motion at night of themselves than they can be made to do in the day-time by external impressions. With a convex lens the rays of the sun may be collected on a leaf, so as to burn a hole in it, without occasioning any motion. But upon trying the experiment on the petiolus, the motion is as quick as if from strong percussion, although the rays be not so much concentrated as to cause pain when applied in the same degree on the back of the hand. The leaves move very fast from the electrical shock, even although very gentle.

AVERRHOISTS. See **AVERROISTS.**

AVERROES, one of the most subtle of the Arabian philosophers, flourished about the end of the eleventh and beginning of the twelfth centuries. He was the son of the high-priest and chief judge of Cordova in Spain; and educated in the university of Morocco, in which he was afterwards a professor; and studied natural philosophy, medicine, mathematics, law, and divinity. After the death of his father he enjoyed his posts; and was farther promoted by Almanzor, emperor of Morocco, to be judge of Morocco and Mauritania, with leave to appoint delegates, and remain at Cordova. But notwithstanding his great emoluments, his liberality to men of letters in necessity, whether they were his friends or his enemies, made him always in debt. He was afterwards stripped of all his posts, and thrown into prison for heresy; but the judge who succeeded him, being convicted of oppression, he was restored to his former employments. He died at Morocco in 1206. Averroes was excessively corpulent, though he eat but once a-day. He spent his nights in the study of philosophy; and when fatigued, amused himself with poetry or history. But was never seen to play at any game, or to partake in any diversion. He was extremely fond of Aristotle's works, and wrote commentaries on them, whence he was styled the commentator, by way of eminence. He likewise wrote *Colliget*, i. e. Universal; or, *The Whole Art of Physic*; and many amorous verses; but these he burnt when he grew old. His other poems are lost. As to religion, his opinions were, that Christianity is absurd; Ju-

daism, the religion of children; and Mahomedanism, the religion of swine.

AVERROISTS, a sect of peripatetic philosophers, who appeared in Italy some time before the restoration of learning, and attacked the immortality of the soul. They took their denomination from Averroes, the celebrated interpreter of Aristotle, above mentioned. Although they held the soul to be mortal, according to reason or philosophy, yet they submitted to the Christian theology, which declares it immortal. But their distinction was held suspicious; and this divorce of faith from reason was condemned by the last council of Lateran, under Leo X.

AVERRUNCATE, } Lat. *averrunco*, I turn
AVERRUNCATION. } or take away whatever hurts. To weed, to avert an evil, to cut off what is superfluous.

I wish myself a pseudo-prophet,
But sure some mischief will come of it,
Unless by providential wit,
Or force, we *averruncate* it. *Butler's Hudibras.*

AVERRUNCI DEI; from *averrunco*, to avert; gods, whose business it was, according to the Pagan theology, to avert misfortunes. Apollo and Hercules were of the number, among the Greeks; Castor and Pollux among the Romans, and Isis among the Egyptians.

AVERSA, a town of Naples, in the Terra di Lavoro, anciently called Atella. It is situated in a fine plain, covered with vineyards and orange trees, and is the seat of a bishop (who holds immediately of the pope), of a royal governor and a judge. There are here sixteen cloisters of different orders, exclusive of nine parish churches. Population 13,800. Eight miles north of Naples. Long. 14° 1' E., lat. 41° N.

AVERSION, according to lord Kames, is opposed to affection, and not to desire, as it commonly is. We have an affection to one person; we have an aversion to another; the former disposes us to do good to its object, the latter to do ill.

AVERSIONE LOCARE, AVERSIONE VENIRE, in the civil law, the selling, or letting things in the lump, without fixing particular prices for each piece.

AVERT,	} <i>A</i> , and <i>verto</i> , <i>versum</i> , to turn away or from. Averse expresses the state of having the mind turned from a thing. It signifies also unwilling, loath, reluctant.
AVERTER,	
AVERTSE,	
AVERTSELY,	
AVERTSE'NESS,	
AVERTSATION,	
AVERTSIVE,	

It is most true, that a natural and secret hatred, and *aversion* towards society in any man, hath somewhat of the savage beast; but it is most untrue, that it should have any character at all of the Divine Nature, except it proceed not out of a pleasure in solitude, but out of a love and desire to sequester a man's self for a higher conversation.

Lord Bacon's Essays.

When people began to espy the falsehood of oracles, whereupon all gentility was built; their hearts were utterly *averted* from it.

Hooker.

Even cut themselves off from the opportunities of proselyting others, by *averting* them from their company.

Government of the Tongue.

There is such a general *aversion* (in human nature) to contempt, that there is scarce any thing more exasperating: I will not deny, but the excess of the *aversion* may be levelled against pride. *Id.*

I beseech you,

T' *avert* your liking a more worthy way,
Than on a wretch. *Shakespeare. King Lear.*

At this, for the last time, she lifts her hand;
Averts her eyes, and half unwilling drops the brand. *Dryden.*

Averters and purgers must go together, as tending all to the same purpose, to divert this rebellious humour and turn it another way.

Burton's Anatomy of Melancholy.

Has thy uncertain bosom ever strove,

With the first tumults of a real love?

Hast thou now dreaded, and now bless'd his sway,
By turns *averse* and joyful to obey? *Prior.*

Averse alike, to flatter or offend;

Not free from faults, nor yet too vain to mend. *Pope.*

The corruption of man is in nothing more manifest, than in his *averseness* to entertain any friendship or familiarity with God. *Atterbury.*

Hatred is the passion of defiance; and there is a kind of *aversion* and hostility included in its essence. *South.*

The jealous man's disease is of so malignant a nature that it converts all it takes into its own nourishment. A cool behaviour is interpreted as an instance of *aversion*: a fond one raises his suspicions. *Addison.*

AVERTI, in horsemanship, is applied to a regular step or motion enjoined in the lessons. In this sense they say *averté*.

AVERY, a place where oats, or provender, are kept for the king's horses.

AVES, birds, the name of Linnæus's second class of animals. See ORNITHOLOGY and ZOOLOGY.

AVES, or the ISLE OF BIRDS, 1. One of the Carribee Islands, 451 miles south of Porto Rico, with a good harbour for careening ships. It is so called from the great number of birds that frequent it; 2. another lying northward of this. Lat. 15° 0' N.; and a third near the eastern coast of Newfoundland. Lat. 50° 5' N.

AVESBURY Robert, an English historian, of whom little more is known, than that he was keeper of the registry of the court of Canterbury, in the reign of Edward III. and consequently that he lived in the fourteenth century. He wrote *Memorabilia gesta magnifici regis Angliæ domini, Edwardi tratii post conquestum, procerumque; tactis primitus quibusdam gestis de tempore patris sui domini Edwardi secundi, quæ in regnis Angliæ, Scotiæ, et Franciæ, ac in Aquitannia et Britannia, non humana sed Dei potentia, contigerunt, per Robertum Avesbury.* This history ends with the battle of Poitiers, about A. D. 1356. It continued in MS. till 1720, when it was printed by the industrious Thomas Hearne at Oxford, from a MS. belonging to Sir Thomas Seabright. It is now very scarce.

AVESI, or AVAST, a river of the United States of America, in the north-western territory, which runs into the Mississippi, in a south-west direction, about sixty miles above the Ohio. It is navigable in boats for upwards of sixty miles.

AVESNES, or AVENNES, an irregular, but well fortified town, on the Helles, in Hainault,

on the frontier of France, towards the Netherlands, and three leagues distant from Maubeuge. It is the head of an arrondissement, in the department of the north; population about 3000. In the neighbourhood there are excellent quarries, and several iron foundries and smelting-houses. This was one of the frontier towns retained for a definite period by the allies, in fulfilment of the treaty of Paris in 1815. Long. 4° E. lat. 50° 7' N.

AVEYRON, or AVEIRON, a department of France, having its name from the river, which running from east to west, separates it into two parts. Its boundaries are to the north, the department of the Cantal; north-east, the Lozere; east, the Gard; south-east, Hérault; south-west, Tarn, and west, Lot. It corresponds to the ancient province of Rouergue, and is divided into five arrondissements; viz. those of Rodez (which is the capital of the department), Ville Franche, Millau, St. Afrique, and Espalion. It contains 474 square leagues, equal to about 3740 square miles, and had at the last enumeration 318,047 inhabitants. They paid in direct taxes in 1803, £140,000 sterling. It constitutes, with the department of Lot, the spiritual jurisdiction of the bishop of Cahors. This department is watered by the Aveyron, the Lot, the Tarn, and the Vieur, and is covered with high and craggy mountains. Hence it abounds in game, fish, and wood, and is more adapted for grazing than for the cultivation of grain. Corn and wine, however, are raised in tolerable quantity. The mineral productions are copper, iron, lead, sulphur, alum, coal, and vitriol. There is also a considerable trade in cattle, wool, woollen stuffs, and in excellent cheese. The climate is reckoned fine, though occasionally severe in winter.

AVEZZANO, a town of Naples in Abruzzo. It is built on an almost imperceptible declivity, one mile from the lake of Celano, to which an avenue of poplars leads from the baronial castle. This edifice stands at a little distance from the town, is square, and flanked with towers; it was erected by Virginio Orsini, to which family this and many other great lordships belonged, before they were wrested from them in times of civil war, and transferred to the Colonas. Avezano was founded in 860, and contains 2800 inhabitants, and two religious communities within its walls, which are indeed in a ruinous condition. The houses are in general mean; but there are some large buildings and opulent families of the class of gentlemen, not possessed of fees held in capite.

AUF. Sometimes written oaf and elf. For definition, see ELF.

These when a child haps to be got,
Which after proves an idiot,
When folk perceive it thriveth not;
The fault therein to smother,
Some silly doating brainless calf,
That understands things by the half,
Says, that the fairy left this *auf*,
And took away the other. *Drayton.*

AUGA, AUGÉ, or AGEA, in fabulous history, the daughter of Aleus, king of Tegea, by Neaira, she was ravished by Hercules, and brought forth a son, whom she left in the woods to conceal her

amors from her father; but the child was preserved, and was named Telephus. When Aleus was informed of his daughter's shame, he delivered her to Nauplius to be put to death; but instead of executing the father's cruel purpose, Nauplius gave Auga to Teuthras, king of Mysia, who, having no children of his own, adopted her as his daughter. The dominions of Teuthras being soon after invaded by an enemy, he promised his crown and daughter to the man who could deliver him from the threatening danger; and Telephus having been directed by the oracle to go to the court of Teuthras, if he desired to find his parents, made an offer of his services, which was accepted. Having obtained a victory, he was about to unite himself to Auga, when she rushed from him with secret horror, and the gods sent a serpent to separate them. Auga implored the assistance of Hercules, by whom her son was made known to her, and she returned with him to Tegea. According to Pausanias, Auga was shut up in a coffer with her infant son, and thrown into the sea, where they were preserved and protected by Minerva, till found by king Teuthras.

AUGEAN CODEX, *Codex Augiensis*, a Greek and Latin MS. of St. Paul's Epistles; supposed by Michaelis to have been written in the ninth century, and so called from Augia major, the name of a monastery at Rheinau, to which it belonged. It came, in 1718, into the hands of the celebrated Dr. Bentley, who purchased it for 250 Dutch florins; it is now in the library of Trinity College, Cambridge. This MS. (noted F. in the second part of Wetstein's New Testament), is written in uncial letters, and without accents, not continua serie, as is common with the more ancient copies, but with intervals between the words, and a dot at the end of each. The Greek text is in capitals, and the Latin in Anglo-Saxon letters; whence it is tolerably clear that it must have been written in the west of Europe, where that formation of the Latin letter was in general use between the seventh and twelfth centuries. The MS. is defective from the beginning to Romans, iii. 8; and the epistle to the Hebrews is only found in the Latin version.

AUGEAS, in fabulous history, king of Elis, famed for his stable, which contained 3000 oxen, and had not been cleaned for thirty years. Hercules was desired to clear away the filth in one day; and Augeas promised, if he performed it, to give him a tenth part of the cattle. This task Hercules is said to have executed, by turning the course of the river Alpheus, or, as some say, the Peneus, through the stable, which immediately carried away the dung and filth. Augeas not only refused to stand by his engagement, pretending that Hercules had used artifice, and experienced no labor or trouble, but banished his own son Phyleus from his kingdom, for supporting the claims of the hero. Upon this a war commenced, and Hercules conquered Elis, put Augeas to death, and gave his kingdom to Phyleus. Augeas has been called the son of Sol, because Elis signifies the sun. After his death, the honors usually paid to heroes, were paid to Augeas.

AUGER. Teutonic *Auegher*; Ang.-Sax. *Vol. III.*

Aeg. From the same root we have edge, a tool used in the mechanic arts.

AUGER (Athanasius), a learned classic, and professor of rhetoric at Rouen, and vicar-general of Lescar, published a splendid edition of the works of Isocrates, from the press of Didot, Paris, 3 vols. 4to. 1782; and the works of Lysias in 1783, in 2 vols. 4to. afterwards reprinted together in 5 vols. 8vo. He died at Paris in 1792.

AUGEREAU, (Pierre François Charles), duke of Castiglione, marshal of France; son of a fruit merchant; born at Paris, 1757; served as a carabinier in the French army; went from thence into the Neapolitan service, established himself at Naples, in 1787, as a fencing-master, and was banished thence, in 1792, with the rest of his countrymen. He served, afterwards, as a volunteer in the army of Italy, in which his talents and courage soon gained him promotion. He distinguished himself, in 1794, as general of brigade in the army of the Pyrenees, and, in 1796, as general of division in the army of Italy. He took the pass of Millesimo; made himself master, April 16, of the entrenched camp of the Piedmontese at Ceva, afterwards of that at Casale; threw himself on the bridge of Lodi, and carried it with the enemy's intrenchments. June 16, he passed the Po, and made prisoners the papal troops, together with the cardinal legate and the general's staff. Aug. 1, he came to the assistance of Masséna; maintained, during a whole day, a most obstinate struggle against a superior number of troops, and took the village of Castiglione, from which he derived his ducal title. Aug. 25, he passed over the Adige, and drove back the enemy as far as Roveredo. In the battle of Arcole, when the French columns wavered, Augereau seized a standard, rushed upon the enemy, and gained the victory. The directory bestowed this standard on him Jan. 27, 1797. Aug. 9, he was named commander of the 17th military division (division of Paris), in place of general Hatry. He was the instrument of the violent proceedings of the 18th of Fructidor, and was saluted, by the decimated legislative body, as the saviour of his country. In 1799, he was chosen member of the council of five hundred, and, therefore, resigned his command. He then obtained from the consul, Buonaparte, the command of the army in Holland. He led the French and Batavian army on the Lower Rhine to the support of Moreau, passed the river at Frankfort, and fought with the imperial general, with various success, until the battle of Hohenlinden ended the campaign. In October of 1801, being superseded by general Victor, he remained without employment till 1803, when he was appointed to lead the army, collected at Bayonne, against Portugal. When this enterprise failed, he went back to Paris, and, May 19, 1804, was named marshal of the empire, and grand officer of the legion of honor. In July of this year, the king of Spain sent him the order of Charles III. At the end of 1805, he was at the head of a corps of the great army in Germany, formed of troops collected under his command at Brest. He contributed to the successes which gave birth to the peace of Presburg, and, in March, 1806, had possession of Wetzlar

and the country around, until, in the autumn of this year, a new war called him to Prussia. The wounds which he received in the battle of Eylau compelled him to return to France. Early in 1811, Napoleon gave him the command of a corps in the army of Spain. Afterwards he returned from thence, and remained without any employment until July, 1813, when he led the army in Bavaria against Saxony, where he took part in the battle of Leipsic. At the entrance of the allies into France, his duty was to cover Lyons. Louis XVIII named him a peer. After the fall of Napoleon, Augereau used reproachful language respecting him in a proclamation to his army. Napoleon, therefore, on his landing in 1815, declared him a traitor. Augereau, however, expressed himself in his favour, but took no active part in the new order of things. After the return of the king, he took his place again in the chamber of peers, sat among Ney's judges, was for a while unoccupied, and died, June 11, 1816, at his estate La Houssaye, of the dyspepsy.

AUGES, in astronomy, two points in a planet's orbit, otherwise called apsides, the one denominated the apogee, the other perigee. See **APSES**.

AUGETTE, in fortification, the wooden pipe which contains the powder by which a mine is fired.

AUGHT. Ang-Sax. hwit, a whit or owhit. See **WAIT**.

AUGLIA, a district and town of Africa, between Siwah and Fezzan. It is included under the dominion of Tripoli, though the subjection is but nominal. This city is of great antiquity, being known in the time of Herodotus. It is about a mile in circumference, but dirty and ill-built; the apartments are dark, there being no aperture for light, except the door. The buildings are also very mean. Dates of excellent quality are produced abundantly. The inhabitants are employed partly in agriculture, but still more in following the caravans which pass through this territory. Long. 22° 25' E., lat. 29° 35' N.

AUGITES, among ancient naturalists, a kind of gem, of a pale green color, inferior in value to the topaz. This mineral is crystallised in small six or eight-sided prisms, with dihedral summits. Its colors are green, brown, and black. Internal lustre shining. Uneven fracture. Translucent. Easily broken. It scratches glass. Specific gravity 3.3. Melts into a black enamel. Its composition, according to Klaproth, is forty-eight silica, twenty-four lime, twelve oxide of iron, 8.75 magnesia, five alumina, and one manganese.

AUGMENT, *v. & n.* } *Lat. augmentum, from*
AUGMENTATION, } *augere, to increase. To*
AUGMENTATIVE, } *put a smaller quantity*
AUGMENTER, } *to a greater, to enlarge,*
 to make greater, and so to strengthen.

AUGMENTED, a musical term, used in contradistinction to perfect, major, minor, and diminished: thus, an augmented note forms an interval of three chromatic degrees; as C, d-sharp; E, flat, f-sharp; F, g-sharp. See **INTERVALS**. Augmented intervals become, by inversion, diminished.

AUGMENTATION OF LIVINGS. The shamefully

poor livings of many of the inferior clergy of the church of England, attracted the attention of the legislature so long ago as the reign of queen Anne. The governors of the bounty of queen Anne, for the augmentation of the maintenance of the poor clergy, by virtue of several acts of parliament made for that purpose, are empowered to augment all livings not exceeding £50 per annum; and the number of livings following were certified to be capable of augmentation:

No. of livings.	Rate per annum.	May be augmented.	No. of augmentations.
1071	Under £10	6 times	6426
1467	From £10 to 20	4 —	5868
1126	— 20 to 30	3 —	3378
1049	— 30 to 40	twice	2098
884	— 40 to 50	once	884

5597 Total of augmentations to be made by the bounty before these 5597 livings will exceed £50 a-year. } 18,654

Mr. Chalmers observes, that computing the clear amount of the bounty to make fifty-five augmentations yearly, it will be 339 years, from 1714 (which was the first year in which any livings were augmented), before all the small livings above certified can exceed £50 per annum; and even if one-half of such augmentations should be made, in conjunction with other benefactors (which is not probable) it will still require 226 years before all the above livings will exceed £50 per annum! This is the more disgraceful, considering the immense incomes enjoyed by the superior clergy.

AUGMENTATION, in heraldry, a particular mark of honor, borne either on an escutcheon, or a canton, as argent, a hand, gules, borne by every baronet not being of higher dignity, as in the annexed example.

AUGSBURG, the second place in the kingdom of Bavaria, both in population and celebrity, was formerly one of the free and imperial cities of Germany. It is situated at the confluence of the Wertach and the Lech. Though less flourishing than in former times, it contains a population of about 30,000 individuals, and is well fortified, in the ancient style, having four principal gates and six smaller ones. Augsburg partakes largely in the manufactures and commerce of the country, and has long been distinguished for its engravings; and its considerable bookselling trade, especially in Catholic literature. By means of its agents and bankers, Augsburg is the general medium of exchange with other countries, as well as a central depot for the Neckar, Tyrolese, Greek and Italian wines. This city is venerable from its antiquity, and interesting from its connexion, both with the civil and ecclesiastical history of Germany. In the diet of the empire, Augsburg was originally called Vindelicia, as being the capital of the Vindelicia. When it subsequently fell under the dominion of the Romans, and a colony was settled there by Drusus, it was called Augusta-Vindelicorum and Rhetorum. It is mentioned

by Tacitus (Germ. xli.) as a very splendid city of the province of Rhetiæ. From the Romans it passed to the Alemanni, and subsequently to the Goths and the Franks. Under these its importance declined. It was subsequently in a precarious condition, but revived after Rodolph was elected emperor; several of its former privileges being confirmed by him, and new ones granted. Augsburg is forty miles north-west of Munich. Long. 10° 53' E., lat. 48° 17' N. from Greenwich.

AUGSBURG, a secularised bishopric of Germany, now forming part of the kingdom of Bavaria. It took its name from the imperial city of Augsburg, and was founded so early as the sixth century. The territory of which it was composed contained 1012 square miles, and lay partly along the banks of the Lech, in the direction of the Tyrol, in the margraviate of Beocgau, and partly beyond the Danube, in the principality of Neuburg. The population was computed at 86,000, and the total revenue at 500,000 dollars. The only towns of note are Dillingen and Fussen, with eleven market towns and a number of villages, mostly situated in the northern part of the bishopric, which is by far the most fruitful and populous. The chapter was composed of forty prebendaries, each of whom had a salary of from 1000 to 1700 florins. The bishopric came into the possession of Bavaria in 1802.

AUGSBURG, or AUGUSTAN CONFESSION, a celebrated confession of faith drawn up by Luther and Melancthon, on behalf of themselves and other ancient reformers, and presented, in 1550, to the emperor Charles V. at the diet of Augusta or Augsburg, in the name of the evangelic body. This confession contains twenty-eight chapters; of which the greatest part is employed in representing, with perspicuity and truth, the religious opinions of the Protestants, and the rest in pointing out the errors and abuses that occasioned their separation from the church of Rome. A civil war followed, that lasted upwards of twenty years, but which only spread the new opinions, as they were then called, instead of extirpating them.

AUGUR, *v. & n.* } *Augurium quasi avig-*
 AUGURATE, } *urium, to see; quo modo*
 AUGURATION, } *aves se gererent in volan-*
 AUGURER, } *do, what direction birds*
 AUGURIAL, } *take in flying, Vossius.*
 AUGUROUS, } *Auguries were also taken*
 AUGURY. } *from their singing and*
 feeding. Hence it signifies to notice the movements of birds, and thereby to predict, to foretell future events. We now apply the words generally to predictions of the future by means of any signs or tokens.

Thy face and thy behaviour,
 Which, if my *augury* deceive me not,
 Witness good breeding. *Shakspeare.*

Calchas, the sacred seer, who had in view
 Things present and the past, and things to come,
 foreknew :

Supreme of *augurs.* *Dryden's Fables.*

AUGUR, in Roman antiquity, an officer appointed to foretell future events, by the chattering, flight, and feeding of birds. There was a college or community of them, consisting originally of

three members with respect to the three Luceres, Rhamnenses, and Tatienses; afterwards the number was increased to nine, of whom four were patricians and five plebeians. They bore an augural staff, as the ensign of their authority; and their dignity was so much respected, that they were never deposed, nor any substituted in their place, though they should have been convicted of the most enormous crimes.

AUGURALE, a place in a camp where the general took auspicia. This answered to the Auguratorium in the city. Augurale is also used in Seneca for the ensign or badge of an augur, as the lituus.

AUGURATORIUM, or AUGURACULUM, a building on the Palatine mount, where public auguries were taken.

AUGURELLO (John Aurelio), an Italian poet, born at Rimini, in 1441. He was professor of the belles letters at Treviso, at which place he died in 1524. He wrote several pieces, but his chief work was a Latin poem, entitled *Chrysopœia*, or the art of making gold. He dedicated his poem to Leo X. upon which the pontiff presented him with a large empty purse, and said, 'that as he could make gold he best knew how to fill it.'

AUGURY, is more fully defined the art of foretelling future events, by observations taken from the chattering, singing, feeding, and flight, of birds. It is also used in a more general signification, as comprising all the different kinds of divination. To make his observations, the augur commonly seated himself on a high tower, with his face towards the east, the north on his left hand, and the south on his right. He divided the face of the heavens into four parts, with a crooked staff, after which he sacrificed to the gods, while he covered his head with his vestment. The augurs drew omens from five different things: 1. The phenomena of the heavens, as thunder, lightning, comets, &c. 2. The chirping of birds, as already mentioned: 3. The eagerness or indifference of the sacred chickens in eating the bread which was thrown to them, they interpreted lucky or unlucky: 4. Quadrupeds crossing or appearing in some unfrequented place: 5. From different casualties, which were called *dia*, such as spilling salt on a table, or wine upon clothes, hearing strange noises, stumbling or sneezing, meeting a wolf, hare, fox, or pregnant bitch. The sight of birds on the left hand was always considered as a lucky object, and the words *sinister lævus*, though commonly imagined to be terms of ill luck, were uniformly used by the augurs in an auspicious sense.

Augury was a very ancient superstition. We know from Hesiod, that husbandry was in part regulated by the coming or going of birds; and most probably it had been in use long before his time, as astronomy was then in its infancy. In process of time, these animals seemed to have gained a greater and very wonderful authority, till at last no affair of consequence, either of private or public concern, was undertaken without consulting them. They were looked upon as the interpreters of the gods; and those who were qualified to understand their oracles were held among the chief men in the Greek and Roman

States, and became the assessors of kings, and even of Jupiter himself. However absurd such an institution as a college of augurs may appear in our eyes, yet, like all other extravagant institutions, it had in part its origin from nature. When men considered the wonderful migration of birds, how they disappeared at once, and appeared again at stated times, and could give no guess where they went, it was not unnatural to suppose, that they retired somewhere out of the sphere of this earth, and perhaps approached the ethereal regions, where they might converse with the gods, and thence be enabled to predict events; at least it was not unnatural for a superstitious people to believe this as soon as some impostor was impudent enough to assert it. Add to this, that the disposition in some birds to imitate the human voice, must contribute much to the confirmation of such a doctrine. This institution of augury seems to have been much more ancient than that of aruspicy; for we find many instances of the former in Homer, but not a single one of the latter, though frequent mention is made of sacrifices in that author. Thus it is probable that natural augury gave rise to religious augury, and this to aruspicy, as the mind of man makes a very easy transition from a little truth to a great deal of error. A passage in Aristophanes gave the hint for these observations. In the comedy of the birds, he makes one of them say, 'The greatest blessings which can happen to you, mortals, are derived from us; first, we show you the seasons, viz. spring, winter, autumn. The crane points out the time for sowing, when she flies with her warning notes into Egypt; she bids the sailor hang up his rudder and take his rest, and every prudent man provide himself with winter garments. Next the kite appearing, proclaims another season, viz. when it is time to shear his sheep. After that the swallow informs you when it is time to put on your summer clothes. We are to you (adds the chorus) Ammen, *Dołona*, *Apollo*: for, after consulting us, you undertake every thing; merchandise, purchases, marriages, &c.' Now, it seems not improbable, that the same transition was made in the speculations of men, which appears in the poet's words; and that they were easily induced to think, that the surprising foresight of birds, as to the time of migration, indicated something of a divine nature in them.

AUGUST. Lat. *Augustus*. Said to be so called from the thing signified being consecrated by augury, and on that account was sacred and venerable.

AUGUSTI, Augustus, Lat. The name of the eighth month from January, inclusive. August was dedicated to the honor of Augustus Cæsar, because in the same month he was created consul; thrice triumphed in Rome; subdued Egypt to the Roman empire; and made an end of civil wars; being before called *Sextilis*, or the sixth from March. August was, by our Saxon ancestors (who, like the modern French, gave their months significant names, called *weed-menath*, i. e. weed-month, on account of the great plenty of weeds at that season. It answers to part of the two last months in the year in the new French calendar; coming in being the seventeen last days

of Thermidor, and the fourteen first days of Fructidor.

AUGUSTA, a considerable and flourishing town of Georgia, and the present seat of government. It is pleasantly situated in Richmond county, on the south-west side of Savannah river, upon a beautiful plain, five miles in length, and one and a half in breadth. It is regularly laid out, the streets intersecting one another at right angles, and contains about 250 dwellings. The public buildings are, a church; an academy; a government-house, where the governor, secretary of state, and other public officers transact their business; a market-house; a new stone jail; a spacious building, where the courts of justice are administered, and the legislature hold their sessions; and three ware-houses, large enough to contain 10,000 hogsheads of tobacco. The academy is governed by a board of trustees, who are a body corporate in law. The funds of this institution amount to several thousand pounds sterling. Opposite the centre of the town, a large wooden bridge has been erected across the Savannah, which opens a commodious and easy communication with South Carolina; it is 19 feet wide, and between 700 and 800 in length. It is about 236 miles from the mouth of Savannah river, including its meanders, 120 N. N. W. of Savannah, and 746 S. W. S. of Philadelphia. Population upwards of 4000. Lat. 33° 19' N., long. 80° 46' W.

AUGUSTA, a post town of Maine, on the river Kennebec, 56 miles N. N. E. of Portland, 168 N. E. of Boston. Population, in 1810, 1805; in 1820, 2457. It is a pleasant and flourishing town, and has, by an act of the state legislature, been constituted the seat of the state government after January 1, 1832. Here is an elegant bridge across the Kennebec, consisting of two arches, each 180 feet long. The river is navigable to Augusta for vessels of 100 tons.

AUGUSTA, a county of Virginia, lying partly east and partly west of the North Mount, a ridge of the Alleghany. It is fertile, and contains upwards of 12,000 inhabitants, including slaves. It has a remarkable cascade, called *Falling Spring*.

AUGUSTA, in antiquity, a title given to the Roman empresses, and frequently to the mothers and daughters of the emperors, who had been empresses.

AUGUSTA, in ancient geography, the name of various ancient cities, mostly named after Augustus or his successors: such as,

1. **AUGUSTA,** a city and island in the Adriatic sea, called also *Austa*, on the coast of Dalmatia, near Ragusa, subject to Venice. Long. 17° 50' E., lat. 42° 35' N.

2. **AUGUSTA ACILIA,** a town in Bavaria, now called *Azelburg*.

3. **AUGUSTA AUSCIORUM,** a town of Aquitania, originally called *Climberum*, which name it afterwards resumed. In the middle age, however, it took the name of the people, *Ausci*; and is now called *Auch*.

4. **AUGUSTA BRACCARUM,** a city of Portugal, now called *Braga*.

5. **AUGUSTA DRUSI,** a town in Swabia, now called *Memmingen*.

• 6. **AUGUSTA EMERITA,** a town of Lusitania,

on the Anas, capital of the province; a colony of the Emeriti, now called Merida, in Spanish Estremadura.

7 and 8. *AUGUSTA PRÆTORIA*; 1. a town and colony of Gallia Cisalpina, the capital of the Salsasi; seated at the foot of the Alps Graia, on the Duria; now called Aosta. 2. another in Transylvania; now called Cronstadt.

9. *AUGUSTA RAURACORUM*, a town of Gallia Belgica, six miles east from Basil; now called Augst. From the ruins, which are still to be seen, it appears to have been a considerable colony.

10. *AUGUSTA ROMANDUORUM*, the ancient name of Luxemburg.

11. *AUGUSTA SUSSIONUM*, a town of Gallia Belgica, on the Axona; with great probability supposed to be the Noviodunum Suessionum of Cæsar; now called Soissons.

12. *AUGUSTA TAURINORUM*, a town of the Taurini, at the foot of the Alps, where the Duria Minor falls into the Po; now called Turin.

13. *AUGUSTA TIBERII*, a city of Bavaria; now called Ratisbon.

14. *AUGUSTA TREBA*, a town of the Æqui, near the springs of the river Anio in Italy; now called Trevi, in Umbria.

15. *AUGUSTA TREVIRORUM*, a town of the Treviri; now called Trieres or Treves.

16. *AUGUSTA TRICASSIUM*, the ancient name of Troceres.

17. *AUGUSTA TRINOBANTUM*, the name given by the Romans to London.

18. *AUGUSTA VEROMANDUORUM*, a town of ancient Gaul; now St. Quintin.

AUGUSTA VINDELICORUM, a town of the Licates on the Licus; styled by Tacitus a noble colony of Rhetia; now called Augsburg, in Suabia. See AUGSBURG.

AUGUSTA HISTORIA, in literature, the history of the Roman emperors, from Adrian to Carinus; that is, from A. D. 157 to 285, composed by six Latin writers, viz. Elius Spartianus, Julius Capitolinus, Elius Lampridius, Vulcatius Gallicanus, Trebellius Pollio, and Flavius Vopiscus.

AUGUSTALIS PRÆFECTUS, a title peculiar to a Roman magistrate who governed Egypt, with a power much like that of a proconsul in other provinces.

AUGUSTAN, relating to Augustus, or Augusta.

AUGUSTAN CONFESSION. See AUGSBURG.

AUGUSTICUM, in writers of the middle age, a largess of an emperor to the people or soldiery.

AUGUSTEUM MARMOR, in the natural history of the ancients, a name given to the common green and white marble, so frequent in use with us for tables, &c. and called by our artificers Egyptian marble.

AUGUSTIA, an ancient town in Wallachia, now called Kusty.

AUGUSTIN (St.), the capital town of the province of East Florida, North America, is situated on the Atlantic, on a peninsula, consisting of a narrow strip of land. It is of an oblong figure, intersected by four streets, which cut each other at right angles. It is reckoned a healthy place, and is well supplied with fresh water. It

has a good port, although the breakers, at its entrance, have formed two channels, whose bars have only eight feet of water each. It has a strong castle for its defence; a good parish church, and two hospitals, one for the garrison of troops, and another for the community. It was burned by Sir Francis Drake, in 1586, and by captain Davis, with the Buccaneers, in 1685; but was immediately after rebuilt. In 1702 it was besieged by the English, who, not being able to take the castle, burned and destroyed the town. In 1714 it was again unsuccessfully attacked by the English under general Oglethorpe. Long. 81° 40' W., lat. 29° 58' N.

AUGUSTINE, a cape of South America, in Brasil, on the Atlantic, 300 miles north-east of All-Saints' Bay. Long. 35° 4' W., lat. 8° 30' S.

AUGUSTINE, or *AUSTIN* (St.), the first archbishop of Canterbury, was originally a monk in the convent of St. Andrew at Rome, and educated under St. Gregory, afterwards Pope Gregory I. by whom he was despatched into Britain, with forty other monks, about A. D. 596, to convert the English to Christianity. He landed in the isle of Thanet, and having sent some French interpreters to king Ethelbert, with an account of the errand on which he came, the king gave him leave to convert as many of his subjects as he could, and assigned his place of residence at Doverum, since called Canterbury; here the king himself was converted; whose example had a powerful influence in promoting that of his subjects. Austin now despatched a priest and a monk to Rome, to acquaint the pope with the success of his mission, and to desire his resolution of certain questions. These men brought back with them a pall and several books, vestments, utensils, and ornaments for the churches; with directions to Augustine concerning the settling of episcopal sees in Britain; ordering him not to pull down the idol temples, but to convert them into Christian churches; only destroying the idols, and sprinkling the place with holy water, that the natives, by frequenting the temples they had been always accustomed to, might be the less shocked at their entrance into Christianity. Augustine resided principally at Canterbury, which thus became the metropolitan church of England; and having established bishops in several of the cities, he died A. D. 607. The popish writers ascribe several miracles to him. The observation of his festival was first enjoined in a synod held under Cuthbert, archbishop of Canterbury, and afterwards by the pope's bull in the reign of Edward III.

AUGUSTINE (St.), a famous father of the church, was born at Thagaste, in Numidia, A. D. 354. His father, a burgess of that city, was called Patricius; and his mother, Monica, who being a woman of great virtue, instructed him in the principles of Christianity. In his early youth he was in the rank of the catechumens; and falling dangerously ill, earnestly desired to be baptized, but the violence of the distemper ceasing, his baptism was delayed. His father, who was not yet baptised, made him study at Thagaste, Madaura, and afterwards at Carthage. Augustine having read Cicero's books of philosophy, applied himself to the study of the scriptures; but suf-

ferred himself to be seduced by the Manicheans. At the age of nineteen he returned to Thagaste, taught grammar, and frequented the bar; he afterwards taught rhetoric at Carthage with applause. The insolence of the scholars at Carthage made him take a resolution to go to Rome, though against his mother's will. Here also he had many scholars; yet he quitted Rome, settled at Milan, and was chosen professor of rhetoric in that city. Here he had opportunities of hearing the sermons of St. Ambrose, which, together with the study of St. Paul's epistles, and the conversion of two of his friends, determined him to retract his errors, and quit the sect of the Manicheans: this was in the thirty-second year of his age. In the year 386 he retired to the house of a friend of his, named Verecundus, where he seriously applied himself to the study of the Christian religion, to prepare himself for baptism, which he received at Easter, in 387. He went to Africa about the end of 388; and having obtained a garden-plot without the walls of the city of Hippo, he associated himself with eleven other persons of eminent sanctity, who distinguished themselves by wearing leathern girdles, and lived there in a monastic way for three years, exercising themselves in fasting, prayer, study, and meditation, day and night; from hence sprung up the Augustine friars, or eremites, of St. Augustine, the first order of mendicants. About this time, or before it, Valerius, bishop of Hippo, against his will, ordained him priest: nevertheless, he continued to reside in his little monastery, with his brethren, who, renouncing all property, possessed their goods in common. Valerius, who had appointed St. Augustine to preach in his palace, allowed him to do it in his presence, contrary to the custom of the churches in Africa. He explained the creed, in a general council of Africa, held in 393. Two years after, Valerius, fearing he might be preferred to be bishop of another church, appointed him his colleague, and caused him to be ordained bishop of Hippo, by Megalus, bishop of Calame, then primate of Numidia. St. Augustine died the twenty-eighth day of August, 430, aged seventy-six, having had the misfortune to see his country invaded by the Vandals, and the city where he was bishop besieged for seven months. His works make ten volumes; the best edition of them is that of Maurin, printed at Antwerp, in 1700.

AUGUSTINE (Anthony), an eminent prelate, born at Saragossa, in Spain. He was employed by the pope on an embassy to England, in 1554; and afterwards assisted at the council of Trent. In 1574 he was preferred to the archbishopric of Tarragona. So great was his charity, that at his death, in 1586, he did not leave what was sufficient to defray his funeral expences. He wrote several treatises on law, and on medals, in the Spanish language, which were printed in 1587.

AUGUSTINE (Leonard), or **AGOSTINI**, an Italian antiquary, was a native of Sienna, and flourished in the seventeenth century. He compiled an elaborate work on ancient gems, which was first published in 1657, in two volumes, 4to. and again in 1707, four volumes, 4to. A Latin translation of this work, by Gronovius, was pub-

lished at Amsterdam in 1685, and at Franeker in 1694.

AUGUSTINE, MOUNT, ST. a remarkable island within the entrance of Cook's islet, about six miles from its western shore. It was seen by Capt. Cook, who was doubtful whether it did not belong to the continent. It was since visited, in 1794, by Mr. Puget, who, in the Chatham, sailed round the world, in company with Vancouver. He states it to be about nine leagues in circuit.

AUGUSTINE, ST. a port on the coast of Labrador, opposite St. John's Bay, Newfoundland. About two miles south-west runs a chain of small islands, called St. Augustine's Chain, about long. 58° 50' west, and lat. 51° 11' north.

AUGUSTINE'S SQUARE, ST. a number of small islands in the Gulf of St. Lawrence, Labrador, reaching from Shecatia bay on the north-east, to Outer Island on the south-west.

AUGUSTINIANS, divines who maintain, on the authority of St. Augustine, that grace is effectual from its nature, absolutely and morally, and not relatively and gradually. They are divided into rigid and related.

AUGUSTINIANS, or **AUGUSTINS**, an order of religious; so called from St. Augustine, whose rule they observe. The Augustins, or Austin friars, were originally hermits, whom pope Alexander IV. first congregated into one body, under their general Lanfranc, in 1256. Soon after, this order was brought into England, where they had about thirty-two houses at the time of their suppression. The Augustins are clothed in black, and make one of the four orders' of mendicants. From these arose others, under the denomination of bare-foot Augustins, Minorites, or Friars minor. There are also canons regular of St. Augustine, who are clothed in white, excepting their cope, which is black. At Paris they are known under the denomination of religious of Genevieve; that abbey being the chief of the order. There are also nuns and canonesses, who observe the rules of St. Augustine.

AUGUSTINUS, a work of Jansenius, bishop of Ypres, in three volumes, folio, printed at Louvain in 1540; the first whereof contains a discourse against Pelagianism; and the second, treatises on reason; the use of authority in theological matters; the state of innocence; fall of nature by sin; grace, &c. From these treatises the five famous propositions of the Jansenists were collected.

AUGUSTOBONA, a city of the Tricasses, in ancient Gaul, from whom it was afterwards called Tricasses, and Treccassæ; and still farther corrupted to Thracæ, or Trecci; whence its modern name Troyes.

AUGUSTOBRIGA, an ancient town of Spain, now called Medina Celi.

AUGUSTODUNUM, the capital of the Ædui, where there was a famous academy for the education of youth; now called Autun.

AUGUSTOMAGUS, an ancient town of Gallia Belgica, now called Senlis, in the Isle of France. Long. 2° 40' E, lat. 49° 12' N.

AUGUSTONIMETUM, a town of ancient Gaul, now Nevers.

AUGUSTORITUM, according to some au-

thors the capital of the Pictones, afterwards called Pictavi; now Poitiers. But by Antonine's Itinerary from Burdigala to Argantomagus (or Argenton, as it is interpreted by many), it can be no other but the capital of the Lemovices, now Limoges, situated between Vesunna or Petrocorii, or Perigueux, and Argantomagus. Long. 1° 22' E. lat. 45° 52' N.

AUGUSTALIA, in Roman antiquity, a festival on which games (*Augustales ludi*) were celebrated, in Rome, annually, on the day of the return of Augustus Cæsar, at the conclusion of his wars. It was instituted ann. U. C. 735, and kept on the IVth ides (12th) of October. After his decease, the tribunes of the people asked permission to celebrate the festival at their own private expense.

AUGUSTALES SODALES, priests instituted by Tiberius after the apotheosis of Augustus Cæsar, to perform the service of the new god. One and twenty of the noblest Romans were chosen by lot to this office; and among the first members were Tiberius himself, Drusus, Claudius, and Germanicus.

AUGUSTOWO, or **AUGUSTOW**, a town in the department of Lomza, Poland. It contains 2000 inhabitants, and has a staple for salt, fifty-six miles north-west of Rielsk.

AUGUSTULUS, otherwise called Flavius Romulus Augustus, was the son of Orestes, and the last Roman emperor. Being subdued by Odoacer, the king of the Heruli, he abdicated the throne, in 475, and thus put an end to the western empire, after it had subsisted 522 years from the battle of Pharsalia. This prince is represented on some medals, as in the annexed figure; inscription, D. N. ROMULUS AUGUSTULUS. P. F. AUG.

AUGUSTUS, an appellation conferred upon Cæsar Octavianus. See **OCTAVIANUS**, and **ROME**. The obscure name of Octavianus, Mr. Gibbon observes, he derived from a mean family in Aricia. It was stained with the blood of the proscription; and he was desirous, had it been possible, to erase all memory of his former life. The illustrious surname of Cæsar he had assumed as the adopted son of the dictator; but he had too much sense either to hope to be confounded, or to be compared with that extraordinary man. It was proposed in the senate, to dignify their minister with a new appellation; and after a very serious discussion, that of Augustus was chosen among several others, as being the most expressive of the character of peace and sanctity which he uniformly affected. Augustus was therefore a personal, Cæsar a family, distinction. The former should naturally have expired with the prince on whom it was bestowed; and however the latter was diffused by adoption and female alliance, Nero was the last who could allege any hereditary claim to the honors of the Julian line. But at his death, the practice of a century had inseparably connected those appellations with the imperial dignity, and they have been preserved by a long succession of emperors, Romans, Greeks, Franks, and Ger-

mans, from the fall of the republic to the present time. A distinction was, however, soon introduced. The sacred title of Augustus was always reserved for the monarch; the name of Cæsar was more freely communicated to his relations; and from the reign of Adrian, at least, was appropriated to the second person in the state, who was considered as the presumptive heir of the empire.

AUGUSTUS FORT, a small fortress of Scotland, in Invernesshire, at the head of Lochness, between the rivers Taarf and Oich. The name of this fort in Erse is Killchuimin, or the burial place of the Cummins. It lies on the road to the Isle of Sky.

AU-GUY-L'AN-NEUF, or **AUGUILLANNEUF**. See **MISLETO**.

AVIA. See **AQUILA**.

AVIARY. Lat. *avis*, a bird. A place where birds are kept.

In *aviaries* of wire, to keep birds of all sorts, the Italians bestow vast expense; including great scope of ground, variety of bushes, trees of good height, running waters, and sometimes a stove annexed, to contemper the air in the winter. *Wotton's Architecture*.

Look now to your *aviary*; for now the birds grow sick of their feathers. *Evelyn's Calendar*.

AVIARY is now used for any place for which birds are kept, but more particularly where the beauty of their plumage or the sweetness of their song has been the cause of their confinement. Lænius Strabo, an opulent and luxurious Roman, was the first who introduced aviaries upon an extensive scale, and erected a splendid one at his villa near Brundisium. Varro, however, outshone all in his ornithological buildings, and elegant and spacious aviary, at his country house near Casinum. With evident satisfaction, he relates, that in his days there were two sorts of aviaries, one for containing birds intended for the table, and the other the birds which were kept for their song or plumage. The former sort were built entirely for use, but the latter were often beautiful pavilions, with an apartment or saloon in the centre, for the company to sit in and enjoy the melody of the feathered songsters. Aviaries have never, in modern times, equalled the splendor and extent of those of the Romans; yet the aviary at Woburn Abbey, the seat of the Duke of Bedford, is of great extent and value; and Malmaison, one of the palaces of the late Emperor Napoleon, contains an aviary at once large, elegant, and well stocked with birds from all quarters of the globe.

AVICENA, **AVICENES**, or **AVICENNA**, the prince of Arabian philosophers and physicians, was born at Assena, a village near Bokhara. His father was a Persian, and had married at Bokhara. The first years of Avicenna were devoted to the study of the Koran and the Belles Lettres. His progress was so rapid, that when he was but ten years old, he was perfectly acquainted with the most hidden senses of the Koran. Abu-Abdollah at that time professed philosophy at Bokhara with great reputation. Avicenna studied logic under him; but, disgusted with the slow manner of the schools, he set about studying alone, and read all the authors that had written on philosophy, without any other

help than that of the commentators. After reading the first six propositions of Euclid, he proceeded alone to the last, having made himself perfect master of them, and treasured up all of them equally in his memory. Endued with an extreme avidity for all the sciences, he did not neglect the study of medicine. Persuaded that this divine art consists as much in practice as in theory, he sought all opportunities of seeing the sick; and afterwards confessed that he had learned more from experience than from all the books he had read. He was now in his sixteenth year, and was already celebrated as the light of his age. He resolved at this age to resume his philosophical studies, which medicine had made him neglect; and he spent a year and a half without ever sleeping a whole night together. If he felt himself oppressed by sleep, or exhausted by study, a glass of wine refreshed his wasted spirits, and gave him new vigor. At the age of twenty-one he conceived the bold design of incorporating, in one work, all the objects of human knowledge; and carried it into execution in an Encyclopædia of twenty volumes, to which he gave the title of the Utility of Utilities; an immense labor for one man at such a period. Several great princes had been taken dangerously ill, and Avicena was the only one that knew their ailments and cured them. His reputation increased daily, and all the kings of Asia desired to retain him as their physician. Mahmud, the first sultan of the dynasty of the Samanides, was then the most powerful prince of the east. Imagining that an implicit obedience should be paid by all manner of persons to the injunctions of his will, he wrote a haughty letter to Mamun sultan of Kharazm, ordering him to send Avicena to him, who was at his court, with several other learned men. Philosophy, the friend of liberty and independence, looks down with scorn on the shackles of tyranny. Avicena, accustomed to the most flattering distinctions among the great, could not endure the imperious manner of Mahmud's inviting him to his court, and refused to go. But the sultan of Kharazm, who dreaded his resentment, obliged the philosopher to depart, with others, whom that prince had demanded to be sent to him. Avicena pretended to obey; but, instead of repairing to Gazna, he took the rout of Georgian. Mahmud, who had gloried in the thoughts of keeping him at his palace, was greatly irritated at his flight. He despatched portraits, done in crayons, of this philosopher to all the princes of Asia, with orders to have him conducted to Gazna, if he appeared in their courts. But Avicena had fortunately escaped the most diligent search after him. He arrived in the capital of Georgian, where, under a disguised name, he performed many admirable cures. Cabous then reigned in that country. A nephew whom he was extremely fond of, having fallen sick, the most able physicians were called, and none of them were able to know his ailment, or give him any ease. Avicena was at last consulted. So soon as he had felt the young prince's pulse, he was confident that his illness proceeded from a passion which he durst not avow. Avicena commanded the prince, who had the care of the different apart-

ments of the palace to name them all in their respective order. A more lively motion in the prince's pulse, at hearing one of these apartments mentioned, betrayed a part of his secret. Avicena then ordered the keeper to name all the female slaves that inhabited that apartment. At the name of one of these beauties the young Cabous could not contain himself; an extraordinary vehemence of his pulse is said to have completed the discovery of what he in vain desired to conceal. Avicena, now fully assured that this slave was the cause of the prince's illness, declared that she alone had the power to cure him. The sultan's consent was necessary, and he of course was curious to converse with his nephew's physician; but had scarce seen him, when he knew in his features those of the portrait sent him by Mahmud: still Cabous, far from forcing Avicena to repair to Gazna, retained him for some time, and heaped honors and presents on him. The philosopher passed afterwards into the court of Nedjmeddevle, sultan of the race of the Bouides. Being appointed first physician to that prince, he found means to gain his confidence to so great a degree that he raised him to the post of grand vizier. This dignity, however, he did not long enjoy. Too great an attachment to pleasure made him lose at once his post and his master's favor. From that time Avicena felt all the rigors of adversity, which he had thus brought upon himself. He wandered about as a fugitive, and was often obliged to shift the place of his habitation to secure his life from danger. He died at Hamadan, aged fifty-eight, A. D. 1036, and in the year of the Hegira 428. No one composed with greater facility than Avicena. He is said to have written fifty pages a-day without fatigue. Until the twelfth century he was preferred for philosophy and medicine to all his predecessors. His works were the only writings in vogue, even in Europe. The following are their titles: 1. Of the Utility and Advantage of Science, 20 books. 2. Of Innocence and Criminality, 2 books. 3. Of Health and Remedies, 18 books. 4. On the means of preserving Health, 3 books. 5. Canons of Physic, 14 books. 6. On Astronomical Observations, 1 book. 7. On Mathematical Sciences. 8. Of Theorems, or Mathematical and Theological Demonstrations, 1 book. 9. On the Arabic Language, and its Proprieties, 10 books. 10. On the Last Judgment. 11. On the Origin of the Soul, and the Resurrection of Bodies. 12. Of the end we should propose to ourselves in Harangues and Philosophical Arguments. 13. Demonstration of collateral Lines in the Sphere. 14. Abridgment of Euclid. 15. On Finiteness and Infinity. 16. On Physics and Metaphysics. 17. On Animals and Vegetables, &c. 18. Encyclopædia, 20 volumes.

AVICENNIA, or AVICENIA, eastern anacardium, a genus of the angiospermia order, and didynamia class of plants; ranking in the natural method under the fortieth order, personata. The calyx is quinquepartite; the corolla is bilabiate, the upper lip squared; the capsule is leathery, romb-like, and monospermous. There are two species, viz. 1. *A. nitida*, the shining, eastern anacardium; and, 2. *A. tomentosa* the downy

anacardium. The seeds are said to be the Malacca beans formerly kept in the shops, the kernels of which were eaten as almonds. Others say that the plant producing the Malacca bean is rather the *bontia germinans*.

AVICH, Loch, anciently called Loch-luina, a lake of Scotland, in the parish of Dalavich, in Argyllshire. Mr. Campbell, in his Statistical Report, says it is 'a beautiful sheet of water, of a regular triangular form, about eight miles in circumference, full of trouts; having a castle and several islands, the resort of gulls, cranes, water eagles, and wild ducks. Near this lake lay the scene of an ancient Celtic poem, called Cathluina, or the conflict of Luina; and in the lake is an island, the scene of another poem, called Laoi Fraoich, or the death of Fraoich. Many places,' he adds, 'in this neighbourhood are still denominated from Ossian's heroes.'

AVICH, a river rising from the above-mentioned lake, and running through a wood, and part of the parish of Dalavich, to which it gives names, and at last falls into Lochow.

AVIDITY, } Lat. *avidus*; from *aveo*, I
AVIDIOUSLY. } desire earnestly. Covetousness, greediness, insatiable appetite.

For nothing is more *avidously* to be desired, than is the sweet peace of God.

Bale's Image of both Churches, part i.

No writings would have been received with such *avidity* and respect as those.

Paley's Evidences.

AVIENUS, Rufus Festus, a Latin poet of the fourth century. He translated the *Phænomena* of Aratus, the description of the earth by Dionysius, *Æsop's Fables*, &c. An edition of his works was printed at Paris in 1590, and again in 1731.

AVIGATO PEAR. See LAURUS.

AVIGLIANO, a small town of Piedmont in Italy, seven miles west of Turin.

AVIGNON, a city of France, in the department of Vaucluse, on the banks of the Rhone, 168 leagues from Paris. Before the revolution it was subject to the Pope; and the residence of several of them in it had rendered it considerable. This occasioned many of the natives to be enemies to the new government; especially after the Convention had abolished the establishment of the Roman Catholic religion in France; and was the cause of much bloodshed. It is now, however, completely annexed to France. Near the Rhone there is a large rock, within the circumference of the walls, upon which is a platform, whence may be had a prospect of the whole city and its environs. Its circumference is somewhat more than three miles. Its manufactories are silks, saltpetre, oil of vitriol, and aqua-fortis. Its products, wine, brandy, almonds, olives, oil, saffron, truffles, corn, and wool; and it contains a well-regulated lunatic asylum, and an hospital of invalid soldiers which lodges 1500 in-pensioners. Before the French revolution its population exceeded 30,000; but in the latest census they are 23,311. It is the seat of a bishop, whose diocese contains the departments of Vaucluse and the Gard; and, in 1803, an university, or Lycœum, was established here.

Avignon was ceded by Philip III. of France to the see of Rome in 1273. On the decease of Benedict XI. the papal court was transferred here; and the six successive pontiffs, Clement V. John XXII. Benedict XII. Clement VI. Innocent VI. and Urban V. made it their only abode. The entreaties of Petrarch were often addressed to the four last. He was well acquainted with Avignon, which had been the residence of his father; and the celebrated fountain of Vacluse, but a short distance from its walls, has been immortalised by the complaints of his unreturned love. The tomb of Laura is still shown in the church of the Cordeliers; and her husband, Hugh de Sade, sleeps there by her side. He speaks of it as the sink of vice and corruption, as an object of universal hatred and contempt, as barbarous, and as the mystic Babylon. Yet for seventy years, from 1309, it continued to be the seat of the holy see; and after the death of Gregory XI. who returned once more to the Vatican, on the commencement of the great schism of the west, during forty years more, the two rival pontiffs of the day thundered their respective excommunications against each other from the banks of the Rhone and of the Tiber. The election of Martin V. terminated the distraction, and Rome once again became the single metropolis of the papacy. During its subjection to the papal see, Avignon was several times seized by France: once in 1662, when the French ambassador at Rome had been insulted by the Corsican guards; again in 1688; and again in 1733, on account of the loss occasioned to the French revenue by smuggling. Another instance of seizure happened in 1768, when pope Clement XIII. threatened to excommunicate the duke of Parma, and took the Jesuits under his protection; it was not given back till 1774, by which time the papal chair had changed its occupant. The Count de Grignan, the husband of Madame de Sevigné's daughter, held it as viceroy for two years, and many of Madame de Sevigné's letters are addressed to Avignon.

AVIGNON BERRY, the fruit of a species of lycœum, which grows plentifully near Avignon and in other parts of France. The berry is somewhat less than a pea; its color is green, approaching towards a yellow; and it is of an astringent and bitter taste. It is much used by the dyers, who stain a yellow color with it; and by the painters, who also make a fine golden yellow of it.

AVILA, a city of Spain in Old Castile, seated on an eminence on the banks of the river Adaja, and in sight of the mountains of Pico. It is fortified both by nature and art, having had a wall 9075 feet in circumference, adorned with lofty towers and handsome gates. The houses are generally good and stately. It has an university, and a considerable bishopric; besides a cathedral, which has eight dignitaries and forty canons and minor canons. It stands in the middle of a large plain, surrounded with mountains and covered with fruit-trees and vineyards. There is likewise a manufacture of cloth.

AVILA, or AVILES, a town of Spain, in Asturias, on the Bay of Biscay, eight miles south of Cape de Pinas, and twenty-five north of Oviedo

AVILA (Giles Gonzales,) a Spanish historian. He went to Rome for his education, and when he returned to his own country obtained a rich benefice, and was appointed historiographer to the king. He wrote a Treatise on the Antiquities of Salamanca, also the Theatre of the Churches of India, and other works. He died in 1658.

AVILA (Louis d'), a Spanish gentleman sent by Charles the Fifth, as ambassador to the popes Paul IV. and Pius V. and was afterwards a commander at the siege of Metz. He wrote historical memoirs of the wars of Charles V. against the Protestants of Germany, entitled 'Los Comentarios de la Guerra del Emperador Carlos V. contra los Protestantes de Alemania;' first printed in 1546, and afterwards translated into French and Latin. He also wrote Memoirs of the War in Africa.

AUJILAH, an oasis, in the great Sahrà, or Lybian desert, in lat. 29° 30' N. and long. 22° 30' E. through which Mr. Hornemann passed in 1798. He says, there are three towns in the territory of Aujilah, the capital of that name, Mojabrah, and Meledilah; the latter are near each other, and both about four hours distant from Aujilah. That city is about a mile in circumference; ill built, though of stone, dirty, and wretched. Mojabrah, is smaller but more populous; its inhabitants are principally engaged in commerce, as those of Meledilah are in agriculture. The women are skilful weavers, and export their cloths to Fezzàn. The soil round the town is sandy, but fertile when well watered. It is subject to Tripoli, and the Bey of Benghazi was resident there during his visit.

AVILER (Augustine Charles d'), a French architect, born in 1653. He was taken by the Algerines in his passage to Rome, and carried to Tunis, where he designed a grand mosque, which is much admired. He was liberated after two years, and settled at Montpellier, where he died, in 1700. He wrote a Course of Architecture, in 4 vols. 4to.

AVIO, a town of Germany in the bishopric of Trent, a little west of the Adige.

AVIS, a river of Portugal, in Alentejo.

AVIS, or **AVIZ**, a small town of Portugal, in Alentejo, seated on an eminence with a castle near the river.

AVIS, **KNIGHTS OF**, an order of knighthood in Portugal, established about A. D. 1162. When Evora was taken from the Moors, in the reign of Alphonso I. king of Portugal, it was garrisoned by several persons who assumed the title of knights of St. Mary of Evora, which was soon after changed for that of knights of Avis, which town the king gave them, and whither they removed from Avora. The badge of the order is a green cross flory, and they observe the rule of St. Benedict.

AVIS LONGA, a name given by Nieremberg to the hoitlattot of the Americans, a bird remarkable for the swiftness of its running.

AVIS NIVEA, a name under which Nieremberg has described an American bird, of the size of a thrush, brown and black on the back, and yellow under the belly; it imitates the human voice, and is called by the natives, coan.

AVIS PENNIPUTRA, the name of an Ameri-

can bird, described by Nieremberg, and called by the Indians quetzaltotol. It is of the size of a pigeon, and is of more beautiful colors than the peacock. There are, besides this species, three or four others. Mr. Ray has, however, ranged all these under the number of birds, the account of which he is either dubious about, or suspicious of the truth of.

AVIS TROPICORUM, the Tropic bird, a bird of the size of the common duck, found only about the tropics.

AVIS VENTI, the bird of the wind. See **HEATOTOTL**.

AVISANDUM, in Scots law, literally advising, or under consideration. A process is said to be under avisandum, when the whole proofs, with the arguments on both sides, are under the consideration of the judge, before he has given an interlocutor or decision upon the cause.

AVIS'ION. Used for **VISION**.

The kinge of this *avision*,
Hath great imagination,
What thinge it signifie maie.

Gouvea, Con. A. book viii. p. 264.

AVISO, *avviso*, Italian; a term chiefly used in matters of commerce to denote an advertisement, an advice, or piece of intelligence.

AVISON (Charles), an English musician of Newcastle, where he practised the whole of his life. In 1752 he published an Essay on Musical Expression, which was favorably received, and reached a second edition in 1763, when it produced published remarks from Dr. Hayes, professor of music at Oxford. Avison quickly retorted, and his reply is appended to the third edition of the original essay. He died at Newcastle in 1770, and left five concertos for the violin, and other compositions, which are esteemed light and elegant.

AVITES, a tribe of Samaritans, who came from Avah, in Chaldea, and were settled by Sennacherib in Samaria. They worshipped the idols Nibhaz and Tartak. 2 Kings xvii. 24—31.

AVITUS, one of the emperors of Rome, in the last stage of its declension. He succeeded Maximus, A. D. 455, and reigned only one year, being cut off and succeeded by Majorians, A. D. 456.

AVI'ZE. See **ADVISE**.

No power he had to stir, nor will to rise;
That when the careful knight 'gan well to rise,
He lightly left the foe. *Faerie Queene.*

As they 'gan his library to view,
And antique registers for to avize. *Spenser.*

With that, the husbandman 'gan him avize,
That it for him was fittest exercise. *Id.*

But him *avizing*, he that dreadful deed
Forbore, and rather chose, with scornful shame,
Him to avenge. *Id.*

AUK, in ornithology, See **ALCA**.

AUKLAND, **BISHOPS**. See **AUCKLAND**.

AULA, is used for a court baron, by Spelman; by some old ecclesiastical writers, for the nave of a church, and sometimes for a courtyard.

AULA REGIA, or **AULA REGIS**, a court established by William the Conqueror in his own hall, composed of the king's great officers of state, who resided in his palace, and were usually attendant

on his person. This court was regulated by the article which forms the eleventh chapter of Magna Charta, and established in Westminster-hall, where it hath ever since continued in operation.

AULD WIFE'S LIFT, an ancient structure, in the parish of Baldernock, Dumbartonshire, about a mile from the church; supposed to be a relict of ancient druidism, and from its name to have been the work of Druidesses. The uppermost stone is eighteen feet long, eleven broad, and six deep.

AULEN, an ancient imperial city of Germany, in the circle of Suabia, thirty miles north of Ulm.

AULETES, *αυλητες*, in antiquity, a flute-player. One of the Ptolemies of Egypt, bore the surname of Auletes.

AULIC, an act, in the Sorbonne and foreign universities, which a young divine maintains upon being admitted a doctor in divinity. It begins by an harangue of the chancellor, addressed to the young doctor; after which he receives the cap, and presides at the aulic or disputations.

AULIC, an epithet given to certain officers of the empire, who compose a court which decides, without appeal, in all processes entered in it. The Aulic council is a jurisdiction of the German empire, established by Maximilian I. in 1502, to counterbalance the authority of the Imperial Chamber. It is called Aulic, because it follows the emperor's court aulæ. The emperor names all the members, consisting of a president, vice-president, and an unlimited number of counsellors; six of whom at least must be Protestants. All points relating to feudal rights and the reserved territories of the emperor in Italy are arranged by this council. In order to prevent any collision with the emperor's will, it sometimes contents itself with making a report to him in the form 'fiat votum ad Cæsarem.' Following the emperor's court, it is sometimes called *justitiam imperatoris*, the emperor's justice. The aulic court ceases at the death of the emperor.

AULIS, in ancient geography, a sea-port town of Bœotia, over against Chalcis of Eubœa, on the Euripus, where that strait is narrowest; and which were some time joined by a mole or causeway; on a craggy situation, and a village of the Tanagræci, distant from Chalcis three miles. The harbour is famous for the rendezvous of 1000 ships under Agamemnon, previous to the Trojan expedition. It is now entirely destroyed.

AULIUS ATTICUS, a captain of a Roman cohort under Julius Agricola, who was killed in a battle with Galgacus, at the foot of the Grampians. Two urns were dug up in the parish of Redgorton, containing human ashes; one of which Mr. Moncrieff supposes to have contained those of this officer, and the other those of Agricola's son.

AULON, anciently a town and station for ships, in Illyricum, on the Adriatic; now called Volano, a port town on one of the mouths of the Po, on the gulf of Venice.

AULON, or **AULONA**, anciently a town of Elis, in Peloponnesus, on the confines of Messenia. Here stood a temple of Æsculapius.

AULONIAS, an epithet of Æsculapius. See last article.

AULOS, a Grecian long measure, the same with stadium.

AULTGRANDE, a river of Scotland, in the parish of Kiltearn, in Rosshire, which takes its rise from Loch Glass, and after running six miles falls into the sea. Its course for two of these miles is through a deep chasm of an extensive and rugged precipice, called Craig-grande, or the ugly rock; of which the Rev. Mr. Robertson, in his statistical account of the parish, gives the following description. 'This is a deep chasm or abyss, formed by two opposite precipices that rise perpendicularly to a great height, through which the Aultgrande runs for the space of two miles. It begins at the distance of four miles from the sea, by a bold projection into the channel of the river, which it diminishes in breadth by at least one half. The river continues to run with rapidity for about three quarters of a mile, when it is confined by a sudden jutting out of the rock. Here, the side view from the summit is very striking. The course of the stream being thus impeded, it whirls and foams, and beats with violence against the opposing rock, till, collecting strength, it shoots up perpendicularly with great fury, and forcing its way, darts with the swiftness of an arrow through the winding passage on the other side. After passing this obstruction, it becomes in many places invisible, owing partly to the increasing depth and narrowness of the chasm, and partly to the view being intercepted by the numerous branches of trees which grow on each side of the precipice. About a quarter of a mile further down, the country people have thrown a slight bridge, composed of trunks of trees covered with turf, over the rock, where the chasm is about sixteen feet wide. Here the observer, if he has intrepidity enough to venture himself on such a tottering support, and can look down the gulph below without any uneasy sensations, will be gratified with a view equally awful and astonishing. The wildness of the steep and rugged rocks; the gloomy horror of the cliffs and caverns, inaccessible by mortal tread, and where the genial rays of the sun never yet penetrated; the waterfalls which are heard pouring down in different parts of the precipice, with sounds various in proportion to their distance; the hoarse and hollow murmuring of the river, which runs at the depth of nearly 130 feet below the surface of the earth; fine groves of pines, which majestically climb the sides of a beautiful eminence, that rises immediately from the brink of the chasm; all these objects cannot be contemplated without exciting emotions of wonder and admiration in the mind of every beholder. The appearance of this singular and picturesque scene, will naturally bring to the recollection of the classical spectator those beautiful lines of Virgil, in which he describes the gulph, through which his Ælecto shoots herself into the infernal regions :

—densis hunc frondibus atrum

Urget utrinque latus nemoris, medioque irragosus

Dat sonitum saxis et torto vortice torrens

Hic specus horrendum, et sacvi spiracula Ditis

Monstrantur; ruptoque ingens Acheronte vorago

Postiferas aperit fauces. —

Critics may labor to convey the force and meaning of the author's words; and travellers may, by their ingenious descriptions, give us a still more lively idea of their beauty and propriety; but he who would see a living commentary on this noble passage, must visit the rock of Aultgrande.'

AULUS GELLIUS. See GELLIUS.

AUMALE. See ALBEMARLE.

AUME, a Dutch measure for Rhenish wine, containing forty English gallons. The term is now obsolete.

AUMONE, in old law style, alms.—*Bailey*.

AUMONE, tenure in, lands given to a church or manastery.

AUMONIER. See ALMONER.

AUNA, the ancient name of Emly, in Ireland.

AUNCEL weight, an ancient kind of balance, prohibited by several statutes, on account of the many deceits practised by it. It consisted of scales hanging on hooks, fastened at each end of a beam, which a man lifted up on his hand. In many parts of England, auncel weight signifies meat sold by the hand, without scales.

AUNCESTER, ancestor.—*Chaucer*.

AUNE, a river of Devonshire, which runs into the sea, east of Plymouth.

AUNE, a long measure used in France to measure cloths, stuffs, ribbons, &c. At Rouen, it is equal to one English ell: at Calais, to 1'52; at Lyons, to 1'061; and at Paris, to 0'95.

AUNEAU, or AUNBAUX, a town of France, in the department of the Eure and Loire, arrondissement of Chartres, with 250 houses. It has a castle, and some hosiery manufactures. Here the duke of Guise defeated, in 1587, the Germans who had come to the assistance of the Protestants. Five leagues east of Chartres.

AUNEDONACUM, the ancient name of Fontenay, in France.

AUNGERVILLE (Richard,) commonly known by the name of Richard de Bury, was born in 1281 at St. Edmund's Bury in Suffolk, and educated at the university of Oxford: after which he entered into the order of Benedictine monks, and became tutor to Edward Prince of Wales, afterwards king Edward III. Upon the accession of his royal pupil to the throne, he was first appointed cofferer, then treasurer of the wardrobe; archdeacon of Northampton, prebendary of Lincoln, Sarum, and Litchfield, keeper of the privy seal, dean of Wells, and last of all bishop of Durham. He likewise enjoyed the offices of lord high chancellor and treasurer of England: and discharged two important embassies at the court of France. Learned himself, and a patron of letters, he maintained a correspondence with some of the greatest geniuses of the age, particularly with the celebrated Italian poet Petrarch. He was also of a most humane and benevolent temper, and performed many signal acts of charity. Every week he made eight quarters of wheat into bread, and gave it to the poor. Whenever he travelled between Durham and Newcastle, he distributed £3 sterling in alms; between Durham and Stockton £5, between Durham and Aukland five marks, and between Durham and Middleham £5. He founded a public library at Oxford, for the use of the students, which he furnished with the best collection of books then in

England; and appointed five keepers, to whom he granted yearly salaries. At the dissolution of religious houses in the reign of Henry VIII. Durham college, where he fixed the library, being also dissolved, some of the books were removed to the public library, some to Baliol college, and some into the hands of Dr. George Owen, who bought the college of king Edward VI. Bishop Aungerville died at his manor of Aukland, April 24, 1345, and was buried in the south part of the cross isle of the cathedral church of Durham, to which he had been a benefactor. He wrote, 1. *Philobiblos*, containing directions for the management of his library at Oxford, and a great deal in praise of learning in Latin. 2. *Epistolæ Familiarium*; some of which are written to the famous Petrarch. 3. *Orationes ad Principes*; mentioned by Bale and Pits.

AUNIS, or Aunix, the smallest of the ci-devant provinces in France. It was bounded on the north by Poictou, on the west by the ocean, and on the east and south by Saintogne. It is now comprehended in the department of Lower Charente. It is watered by the Seure and the Charente. The coast has the advantage of several ports, the most remarkable of which are Rochefort, Rochelle, Brouge, St. Martin de Re, Tremblade, Tonnai, and Charente. The soil is dry, yet produces good corn and plenty of wine. The marshes feed a great number of cattle, and the salt marshes yield the best salt in Europe.

AUNT. Some ingenuity is necessary to derive this word from the Fr. *tante*—' Lat. *avita* from *avita*, and this from *avia*! In Todd's Johnson it is deduced from the Old Fr. *ante*, from a Celtic root, a father or mother's sister.

Who meets us here? my niece Plantagenet,
Led in the hand of her kind aunt of Glo'ster.

Shakspeare.

She went to plain work, and to purling brooks,
Old fashion'd halls, dull aunts, and croaking rooks.

Pope.

AVOCATORIA, a mandate of the emperor of Germany, addressed to some prince in order to stop proceedings in any cause appealed to him.

AVOCH, or AUACH, Gael. a ford, a parish in Scotland, Rosshire, on the coast of the Moray Frith, and extending about four miles from south to north, and two and a half from east to west.

AVOID, } Fr. *vuider*, or *eviter*. Lat.
AVOID'ABLE, } *evito*. The word *viduus*, in whole
AVOID'ANCE, } or in part, is supposed to be the
AVOID'ER, } etymon. To make void or free
· AVOIDLESS. } from, to leave empty, to go out
of, to move away from, to leave, to escape. The
word *shun* is usually applied to persons, and
avoid to things. 'Avoid the room,' no longer
means, as in Lord Bacon's time, go out of the
room, but 'go not into the room.'

What have you to do here, fellow? pray you,
avoid the house.

Shakspeare.

If any rebel should be required of the prince confederate, the prince confederate should command him to avoid the country.

Bacon.

That *avoidless* ruin in which the whole empire would be involved. *Dennis's Letters.*

Want of exactness in such nice experiments is scarce *avoidable.* *Boyle.*

To take several things for granted, is hardly *avoidable* to any one, whose task it is to shew the falsehood or improbability of any truth. *Locke.*

Now what things can there be of greater moment or importance for men to know or God to reveal, than the nature of God and ourselves, the state and condition of our souls, the only way to *avoid* eternal misery, and enjoy everlasting bliss. *Stillingfleet.*

It is appointed to give us vigour in the pursuit of what is good, or in the *avoidance* of what is hurtful. *Watts.*

AVOIRDUPOIS, *avoir du pois*, French. A kind of weight, of which a pound contains sixteen ounces, and is in proportion to a pound Troy, as seventeen to fourteen. All the larger and coarser commodities are weighed by *avoirdupois* weight. *Avoirdupois* ounce is less than the Troy ounce in the proportion of 700 to 768: but the *avoirdupois* pound is greater than the Troy pound in the proportion of 700 to 576.

AVOIRDUPOIS WEIGHT. For the table of its divisions, see **ARITHMETIC.**

AVO'KE, } Lat. *avoca, avocation*, I call;
AVO'RATE, } from *a*, and *voco*. *Evoke* is now
AVO'RATION, } used instead of the verb. *Avoca-*
tions are those engagements which call off our time and attention from other things.

We have written to your grace in our common letter, for a confirmation of many inconveniences and dangers which we persuaded to his Holiness, to follow both to himself and to the see apostolick, in case his Holiness should *avoke* the cause.

Burnet's Reform Records, vol. i.

For what is a scholar, but one who retireth his person, and *avocate*th his mind, from other occupations and worldly entertainments. *Barrow's Sermons.*

Sorrow ought not to be suffered to increase by indulgence, but must give way after a stated time to social duties and the common *avocations* of life.

Johnson.

Whom could I select with such perfect propriety as yourself, who, like the younger Scipio, can so usefully mingle the *avocations* of business with elegant literature? *Dr. Stuart's Dedication of Sallust.*

AVOLATION. Lat. *avolatio (a volo)*, a flying away from.

These airy vegetables are made by the relics of plantal emissives, whose *avolation* was prevented by the condensed enclosure. *Glanville's Scepis.*

Strangers, or the fungous parcels about candles, only signify a pluvius air, hindering the *avolation* of the favillous particles. *Brown's Vulgar Errors.*

AVON, the name of four rivers in England; viz. 1. rising in Leicestershire, runs south-west by Warwick and Evesham, and falls into the Severn at Tewksbury; 2. in Monmouthshire; 3. rising in Wiltshire, coats the edge of the New Forest, and enters the English channel at Christ Church Bay in Hampshire; and 4. the Lower Avon, which rises near Tetbury in Gloucestersh. and running west to Bath, becomes navigable; continues its course to Bristol, and falls into the Severn north-west of that city.

AVONA PORTICOSA, the ancient name of the isle of Sanda.

AVOSETTA, in ornithology. See **RECURV-ROSTRA.**

AVOU'CH, *v. & n.* } Fr. *avouer*, to affirm.
AVOU'CHER, } To maintain, declare ab-
AVOUCHMENT. } solutely, to vindicate, to justify, to corroborate, to answer for the truth of, to support a statment with documents.

They boldly *avouched* that themselves only had the truth, which they would at all times defend.

Hooker.

Wretched though I seem,
 I can produce a champion that will prove
 What is *avouched* here. *Shakspeare. King Lear.*
 Such authours and *avouchers* of things.

Udall. Luke, cap. i.

But I marvail much that maister Moore beyng a great learned man, would not for the *avouchement* of his credite, and the truth of so great a matter, allege so much as the testimonie and auctoritie of some one author, for the prouyng of his assertion.

Grafton, vol. i.

AVOW, *v. & n.* }
AVOW'ABLE, }
AVOW'AL, } Fr. *avouer*. Lat. *Voveo*, I
AVOW'ED, } vow or promise. To make
AVOW'EDLY, } a solemn declaration, to ac-
AVOWER, } knowledge, to confess.
AVOW'RY. }

His cruel stepdame, seeing what was done,
 Her wicked days with wretched knife did end;
 In death *avowing* th' innocence of her son.

Faerie Queene.

Willnot could not *avowedly* have excepted against the other. *Clarendon.*

He that delivers them mentions his doing it upon his own particular knowledge, or the relation of some credible person, *avowing* it upon his own experience.

Boyle.

Left to myself, I must *avow*, I strove
 From publick shame to screen my secret love.

Dryden.

Virgil makes *Aeneas* a bold *avower* of his own virtues.

Id.

Such assertions proceed from principles which cannot be *avowed* by those who are for preserving church and state.

Swift.

This management, when no *avowable* reason could be given for it, gave suspicious and refining persons occasion to throw out a great deal of slander.

Bolingbroke.

Then blaz'd his smother'd flame, *avow'd* and bold.

Thomson.

AU-PIS-ALLER, a French phrase, sometimes used among English writers, signifying at the worst.

AURA, among physiologists, an airy exhalation or vapor. The word is Latin, derived from the Greek, *αυρα*, gentle wind.

AURA, in chemistry, a name given to that certain fine and pure spirit, found in every animal or vegetable body; but so subtle, as only to be perceptible by its smell and taste, or other effects, not found in any other body. This *aura*, says Boerhaave, exhibits the proper character of the body, and is lodged in the oil of the body, to prevent its being dissipated and thrown off.

AURA, in ornithology, a species of vulture.

AURACH, a town of Germany, with a good castle, in the south part of Suabia, in the duchy of Wirtemberg. It is the usual residence of the youngest sons of the house of Wirtemberg; is

seated at the foot of a mountain on the rivulet Erms, fifteen miles east of Tubingen.

AURÆ, in mythology, a name given by the Romans to the nymphs of the air. They are mostly to be found in the ancient paintings of ceilings; where they are represented as light and airy, generally with long robes and flying veils of some lively color or other, and fluttering about in the rare and pleasing element assigned to them. They were characterised as sportive and happy in themselves, and wellwishers to mankind.

AVRANCHES, a town of Lower Normandy, formerly the capital of the district called Avranchin, and now of an arrondissement in the department of La Manche. It stands on a hill near the Seez, and commands an extensive prospect of the surrounding country. It was formerly the see of a bishop, whose palace still remains, and who was suffragan to the archbishop of Rouen. The cathedral was founded in 1120. It is only half a league distant from the sea, and the tide brings up small vessels close to the town. The inhabitants carry on a traffic in grain, flax, hemp, cattle, butter, wheat, salt, and cyder, which is here made of an excellent quality. Provisions and fuel are both cheap. Population about 6000. Avranches was much resorted to by the English after the peace of 1814. It lies 222 miles due west of Paris. Long. 1° 17' W., lat. 48 41' N.

AURANTIA, in botany, a natural order, comprehending the entire orange tribe. Jussieu is the author of this order, the seventieth in his arrangement; nor are there any traces of it among the fragmenta of Linnaeus. CAL. one leaf, often deeply divided. PER. definite, broad at the base, inserted round a disk on which the germen is placed. STAM. placed on the same disk. GERM. one; style one; stigma simple, or rarely divided. Fruit mostly pulpy, sometimes capsular, of one or many cells, with one or two seeds in each. This order is divided into three sections, according to the seed contained in the fruit. 1. Fruit with only one seed. The leaves are not marked with resinous dots, and hence the plants of this section are termed spurious aurantia. 2. Fruit many-seeded, pulpy. These are genuine aurantia, having the leaves full of pellucid resinous dots. 3. Fruit many-seeded, capsular. Leaves not dotted. Genera akin to aurantia and to melie.

AURANTIAM, in botany. See CITRUS.

AURANTHUS FISCI, in ichthyology, a name given by Nieremberg to the dorado, or dolphin, a species of the coryphæna, distinguished from the others by its forked tail.

AURARIA FUCERIO, pensio, or præstatio, a tax to be paid in gold.

AURATA, in ichthyology, the fish called gilt head.

AURAY, a town in the province of Bretagne, in France, a department of Morbihan, arrondissement of L'Orient, and the head of a canton. It stands on the gulf of Morbihan, and has a harbour, with considerable trade in corn, honey, skins, and salted fish. The only manufactures are a few woollen stuffs. It trades principally with Spain, and receives in exchange for the

above-mentioned articles, Biscay-iron and wine. Population 3200. Four leagues W. of Vannes. Long. 2° 53' W., lat. 47° 40' N.

AUREA ALEXANDRINA, in pharmacy, a kind of opiate, or antidote against the cholice and apoplexy, composed of a great number of ingredients, which was in great fame among the ancient writers. It is called aurea, from the gold (aurum) which is an ingredient in its composition; and Alexandria, as having been invented by a physician named Alexander.

AUREA CHERSONESUS, a name given by ancient authors to Japan.

AUREAPOLIS, an ancient town of Bavaria, now called Ingolstadt.

AUREAT, } Lat. *aurum*, gold; partaking
AURIFÉROUS, } of the nature and qualities of
gold. Poetical epithets.

And sum departe in frecklis rede quhyte,
Sum bright as gold with *aurate* leuis lyte.

Douglas. *Eneados*, Prol. to book xii. p. 401.

Rocks rich in gems, and mountains big with mines,
Whence many a bursting stream *auriferous* plays.

Thomson.

AURELIA, in natural history, the same with what is usually called chrysalis, and sometimes nymph. See CHRYSALIS.

AURELIA, the ancient name of Orleans.

AURELIANUS, Cælius, or, as some have called him, Lucius Cælius Arianus, an ancient physician, and the only one of the sect of the Methodists of whom we have any remains, was of Sicca, a town of Numidia in Africa. This we learn from the elder Pliny, and his style much resembles that of the African writers. It is half Greek, half Latin, harsh, and difficult; yet strong, masculine, full of good sense, and valuable for the matter it contains. It is frequently very acute and smart, especially where he exposes the errors of other physicians, and always nervous. What age Cælius Aurelianus flourished in, cannot be determined; but it is probable that he lived before Galen, as he does not make the least mention of him. He was not only a careful imitator of Soranus, but also a strenuous advocate for him. He had read over very diligently the ancient physicians of all the sects; and to him we are indebted for the knowledge of many dogmas which are not to be found but in his books, 'De Celeribus et Tardis Passionibus.' The best edition of these books is that published at Amsterdam, 1722, in quarto. He wrote, as he himself tells us, several other works; but they have all perished.

AURELIANUS (Lucius Domitius), emperor of Rome, was one of the greatest generals of antiquity, and commanded the armies of the emperor Claudius II. with such glory, that, after the death of that emperor, the legions agreed to place him on the throne, A. D. 270. He was a native of Dacia, born of obscure parentage, and was elected emperor in the fifty-fifth year of his age. He was a man of amazing strength and courage, and had risen through all the gradations of military duty. In one engagement he is said to have killed forty of the enemy with his own hand; and, in the various battles in which he was engaged, above 900 in all. He carried the war from the east to the west with as much faci-

lity, says a modern writer, as a body of troops marches from Alsace into Flanders. He defeated the Goths, Sarmatians, Marcomanni, the Persians, Egyptians, and Vandals; conquered Zenobia, queen of the Palmyrenians, and Tetricus, general of the Gauls, both of whom graced his triumph in 274. In a word, for valor and expedition, he might be compared to Julius Caesar, had he possessed equal clemency and moderation. He showed great clemency indeed to queen Zenobia, although he destroyed her city, for he gave her lands and an income sufficient to maintain her in all the splendor of her former royalty without the trouble of it. But his generosity to that princess was sullied by his ordering her secretary, Longinus, the celebrated critic, to be put to death, whose work on the sublime ought to have procured him respect from any person one degree removed from barbarism. His severities were at last the cause of his destruction. Mnestheus, his secretary, conspired against him, and he was slain by one of his generals in passing with a small guard from Heraclea in Thrace towards Byzantium, A. D. 275, after a very active reign of five years. See **ROME**.

AURELLI, or **ARELLI**, a Latin poet of the sixteenth century, who obtained the government of a district from Leo X. but whose tyrannical behaviour made the inhabitants throw him into a well, in 1520. His poems are much in the manner of Catullus.

AURENGABAD, or **AURUNGABAD**. See **AURUNGABAD**.

AURENG-ZEBE, the Great Mogul, was the third son of Schah Iehan. He was born in 1618, and in his youth feigned an air of religious sanctity, but in 1658 he and his brother Morad seized Agra, and took their father prisoner. Not long after, he put Morad and Dara, another brother, to death. He, however, showed some tenderness towards his father, who died in 1666. Aureng-zebe increased his dominions so much, and became so powerful, that ambassadors were sent to him from all the eastern princes; and for the sake of commercial advantages, many European princes did the same. He died at Ahmednaghur in 1707, aged eighty-nine. His possessions were, by his will, divided among his sons. He was of a low stature, with a large nose, a white beard, and olive complexion. He was slender, and supported himself on a staff; yet he endorsed petitions without spectacles, and seemed pleased with doing business at a public audience. He subdued Visapour, Golconda, and the Carnatic; overran the kingdom of Asen; reduced Bengal; and cleared the mouth of the Ganges from the Portuguese pirates. He had formed a design to destroy all the native princes, and to force a conversion of the Hindoos; but harrassed in his turn by the rebellion of his sons, he was obliged to put off the execution of this momentous endeavour. By his indulgence towards his omrahs and governors his meaner subjects were oppressed with impunity. 'God,' he observed, in his usual sanctimonious manner, 'would punish them if they did evil.' The real state of the case was, that he shared in the fruits of their oppression.

AUREOLA, in ecclesiastical antiquity, ori-

ginally signified a jewel, proposed as a reward of victory in some public dispute. Hence the Roman schoolmen applied it to denote the reward bestowed on martyrs, virgins, and doctors, on account of their works of supererogation; and painters use it to signify the crown of glory with which they adorn the heads of saints, confessors, &c.

AUREOLUS, a Dacian shepherd, who aspired to the empire, but was defeated and slain by Claudius, a general of the emperor Gallienus. This usurper is known by some medals bearing on one side his head, crowned with rays, as in the annexed figure, inscription **IMP. M. ACIL. AUREOLUS P. F. AUG.** on the reverse a goddess, resting on a pillar, with a sceptre in her right hand, a cornucopia in her left, and a globe at her feet, inscription **PROVIDENTIA AUG.**

AUREUS, a Roman gold coin, equal in value to twenty-five denarii, or 100 sesterces. According to Ainsworth, the aureus of the higher empire weighed nearly five pennyweights; and in the lower empire little more than half that weight. Suetonius says, that it was customary to give aurei to the victors in the chariot races.

AUREUS MONS, in ancient geography, 1. A mountain in the north-west of Corsica, whose ridge runs out to the north-east and south-east, forming an elbow. 2. Another of Messia Superior, or Servia, south of the Danube, which the emperor Probus planted with vines; and 3. A town at the foot of it, on the same river.

AURIA (Vincent), a Sicilian writer, born at Palermo, 1625. He was author of several works in Latin and Italian; but the principal are a History of the most eminent Men of Sicily, 1704; and a History of the Viceroy's of Sicily, 1697, folio. He died in 1710.

AURICHALCUM, *οριχαλκος*, mountain-brass; from *oros*, a mountain, and *χαλκος*, brass; the metal now called brass being a mixture of copper and lapis calaminaris. It is called aurichalcum by Plautus, and orichalcum by Virgil and Horace. Plaut. Mil. act. iii. scene 1. v. 64.

Cedo mihi tres homines aurichalco contra cum istis moribus.

AURICULA, in botany. See **PRIMULA**.

AURICULA, in ichthyology, the earwig.

AURICULA JUDE, or **JEW'S EAR**, a kind of fungus, or mushroom, somewhat resembling in figure a human ear. It grows on elder-trees, the tree on which, as some pretend, Judas hanged himself; and hence, they think, the name is derived. This fungus steeped in water and applied to the eyes, is said to free them of inflammation; but its chief use is in the form of a gargle in decoctions against inflammations of the throat, or swellings of the tonsils.

AURICULAR, } Lat. *auricula*, flap of the
AURICULARLY. } ear; sometimes the ear it-
 self. Addressed to the ear—as much as to say,
 to go no further. Private, secret, confidential.

You shall hear us confer, and by an *auricular* as-
 surance have your satisfaction.

Shakespeare. King Lear.

The alchemists call in many varieties out of astro-
 logy, *auricular* traditions, and feigned testimonies.

Bacon.

These will soon confess, and that not *auricularly*,
 but in a loud and audible voice. *Decay of Piety.*

AURICULATED LEAF, in botany, is a leaf
 which has a lobe on each side towards the base.

AURIFLAMMA, in the French history, a
 standard belonging to the abbey of St. Dennis,
 suspended over the tomb of that saint, which the
 religious, on occasion of any war in defence
 of their land or rights, took down, with great cere-
 mony, and gave to their protector or advocate,
 to be borne at the head of their forces. Hence
 the word is sometimes used to denote the chief
 flag or standard of an army.

AURIGA, the waggoner, in astronomy, a
 constellation of the northern hemisphere, consist-
 ing of twenty-three stars, according to Tycho;
 forty, according to Hevelius; and sixty-eight, in
 the Britannic catalogue. It is figured as an old
 man with a goat, her kids in his left hand, and a
 bridle in his right. Capella, the goat, is a star
 of the first magnitude. Its rising was deemed by
 the ancients a prognostic of rain.

AURIGNAC, a town of Gascony, the head of a
 canton, in the department of the Upper Garonne,
 arrondissement of St. Gaudens. The inhabitants,
 who amount to about 1230, trade in cattle, and
 manufacture woollen goods. It is seated on the
 river Louge, fourteen leagues S. E. of Toulouse.

AURIGNY, a small island in the English
 channel, belonging now to England, twenty miles
 north from Jersey, and seven west of Cape La
 Hogne. Long. 2° 9' E., lat. 49° 43' N.

AURIGRAPHUS; from *aurum*, gold, and
γραφω. I write; in the middle age, writers, a
 copyist, or calligrapher, who wrote in gold letters.

AURILLAC, a town of France, on the Jor-
 dane, in Upper Auvergne. At present it is the
 chief town in the department of the Cantal.
 Here are manufactures of woollen stuffs, carpets,
 stamine, shalloon, and lace; in which, as well as
 in cattle and cheese, an active trade is carried on.
 Population 10,332 in 1815. Fifteen leagues south-
 east of Tulle, and 111 south of Paris. Long.
 2° 31' E., lat. 44° 55' N.

AURIOL, a town of France, in the dep-
 artment of the Bouches du Rhone, arrondissement
 of Marseilles. Here are some woollen man-
 ufactures. Population 3700, five leagues north-
 east of Marseilles.

AURIPIGMENTUM. See ORPIMENT.

AURIS, the ear. See ANATOMY, Index.

AURIS ASSINI, ass-ears, a name given by nat-
 uralists to a species of sea-shell, supposed to
 resemble the ear of an ass.

AURIS EXTERNA, the auricle.

AURIS MARINA, ear-shell.

AURIS PORCI, hog's ear, in natural history, a
 sea-shell, a species of the *murex*.

AURISCALPUM, an instrument to clean the

ears, and serving also for other operations in dis-
 orders of that part.

AURISPA (John), a Sicilian writer. He
 was appointed secretary to Nicholas V. from
 whom he obtained two abbeys. He died at
 Ferrara, at the end of the fifteenth century. He
 translated the works of Archimedes, and Hiero-
 cle's Commentary on the golden verses of Py-
 thagoras.

AUROGALLUS (Matthew), professor of lan-
 guages at Wittemberg, was a native of Bohemia;
 he assisted Luther in his translation of the Bible
 into German, and wrote a Hebrew and Chaldee
 Grammar, printed at Basle in 1539. He died
 in 1543.

AURIUM **ABSCISSIO**, cutting off the ears,
 was a punishment inflicted, by the Saxon laws,
 on those who robbed churches; afterwards on
 every thief; and, at length, on divers other crimi-
 nals.

AURON, a river of France, in the department
 of Cher, anciently called Avara.

AURORA, in the mythology, the goddess of
 the morning, was the daughter of Hyperion and
 Theia, according to Hesiod; but of Titan and
 Terra, according to others. It was under this
 name that the ancients deified the light which
 foreruns the rising of the sun above our hemi-
 sphere. The poets represent her as rising out of
 the ocean in a chariot, with rosy fingers dropping
 gentle dew. Virgil describes her ascending in a
 flame colored chariot with four horses. She had
 various lovers, Cephalus, Pandion, Tithonus,
 &c. Aurora is also used for the morning twi-
 light, or that faint light which appears in the
 morning when the sun is within 18° of the horizon.

AURORA, one of the New Hebrides islands in
 the South Sea, in which Mr. Forster supposes
 the Peak d'Etoil, mentioned by Mr. Bouganville
 to be situated. The island is inhabited; but
 none of its inhabitants came off to visit Captain
 Cook. The country is woody, and the vegeta-
 tion seemed to be excessively luxuriant. It is
 about twelve leagues long, but not above five
 miles broad in any part; lying nearly north and
 south. The middle lies in long. 168° 24' E., lat.
 15° 6' S.

AURORA AUSTRALIS, **SOUTHERN LIGHT**, or
STREAMERS, similar to the aurora borealis, or
 northern light, only more clear and white. See
AURORA BOREALIS.

AURORA BOREALIS, **NORTHERN TWILIGHT**, or
Streamers; a kind of meteor appearing in the
 northern parts of the heavens, mostly in the
 winter-time, and in frosty weather. It is now so
 generally known, that no description is requisite
 of the appearance which it usually makes in this
 country. But it is in the arctic regions that it
 appears most remarkable, particularly during
 the solstice. In the Shetland islands, the merry
 dancers, as they are there called, are the constant
 attendants of clear evenings. They commonly
 appear at twilight near the horizon, of a hue
 approaching to yellow; sometimes continuing
 for several hours without any sensible motion;
 after which they break out into streams of stronger
 light, spreading into columns, and altering slowly
 into ten thousand different shapes, varying their
 colors from all the tints of yellow to the obscurest
 russet. They often cover the whole hemisphere,

and then make the most brilliant appearance. Their motions at these times are most amazingly quick; and they astonish the spectator with the rapid change of their form. They break out in places where none were seen before; darting along the heavens, are suddenly extinguished, and leave behind an uniform dusky tract. This again is brilliantly illuminated in the same manner, and as suddenly left a dull blank. Sometimes they assume the appearance of vast columns, on one side of the deepest yellow, on the other declining away till it becomes undistinguishable from the sky. They have generally a tremulous motion from end to end, which continues till the whole vanishes. In a word, we, who only see the extremities of these northern phenomena, have but a faint idea of their splendor and their motions. According to the state of the atmosphere, they differ in colors. They often put on the color of blood, and make a dreadful appearance. The rustic sages become prophetic, and terrify the gazing spectators with the dread of war, pestilence, and famine. This superstition was not peculiar to the northern islands; nor are these appearances of a recent date. The ancients called them Chasmata, and Trabes, and Bolides, according to their forms or colors. The Aurora Borealis in this country, appears usually of a reddish color, inclining to yellow, and sends out frequent coruscations of pale light, which seem to rise from the horizon in a pyramidal undulating form, and shooting with great velocity up to the zenith. They appear often in the form of an arch, which is partly bright, and partly dark, but generally transparent: and the matter of them is not found to have any effect on the rays of light, which pass freely through them. Dr. Hamilton observes, that he could plainly discern the smallest speck in the Pleiades through the density of those clouds which formed part of the aurora borealis in 1763, without the least diminution of its splendor, or increase of twinkling. Sometimes it produces an iris; and hence, M. Godin judges, that most of the extraordinary meteors and phenomena in the skies, related as prodigies by historians, as battles, and the like, may probably enough be reduced to the class of aurora borealis. This kind of meteor never appears near the equator; but it seems, is frequent enough towards the south pole, like as towards the north, having been observed there by voyagers. See Philosophical Transactions, No. 461, and vol. liv.; also Forster's account of his voyage round the world with Captain Cook, where he describes their appearance, as observed for several nights together, in sharp frosty weather, which was much the same as those observed in the north, excepting that they were of a lighter color. Meteors of this kind have appeared more frequently at some periods than others; whence it would seem, that the air, or earth, or both, is not at all times disposed to produce this phenomenon. The extent of these appearances is also amazingly great. That which occurred in March, 1716, was visible from the west of Ireland to the confines of Russia, and the east of Poland; extending at least near thirty degrees of longitude, and from about the fiftieth degree in latitude, over

almost all the north of Europe; and in all places, at the same time, it exhibited the like wondrous appearances. Father Boscovich has determined the height of an aurora borealis, which was observed by the marquis of Polini the 16th of December, 1737, and found it was 825 miles high; and Mr. Bergnian, from a mean of thirty computations, makes the average height of the aurora borealis amount to seventy Swedish, or 469 English miles. But Euler supposes the height to be several thousands of miles; and Mairan also assigns to them a very elevated region. Many attempts have been made to determine the cause of this phenomenon. Dr. Halley imagines that the vapors, or effluvia, exceedingly rarefied by subterraneous fire, and tinged with sulphureous steams, which many naturalists have supposed to be the cause of earthquakes, may also be the cause of this appearance; or that it is produced by a kind of subtle matter, freely pervading the pores of the earth, and which, entering into it nearer the southern pole, passes out again with some force into the æther, at the same distance from the north. This subtle matter, by becoming more dense, or having its velocity increased, may perhaps be capable of producing a small degree of light, after the manner of effluvia from electric bodies, which, by a strong and quick friction, emit light in the dark; to which sort of light this seems to have an affinity. On this subject see Philosophical Transactions No. 347; and also Mr. Cotes's description of this phenomenon, and his method of explaining it, by streams emitted from the heterogeneous and fermenting vapors of the atmosphere, in Smith's Optics, p. 69. The celebrated M. de Mairan, in an express treatise on the aurora borealis, published in 1731, supposes its cause to be the zodiacal light, which according to him, is no other than the sun's atmosphere; this light happening, on some occasions, to meet the upper part of our atmosphere about the limits where universal gravity begins to act more forcibly towards the sun, falls into our air to a greater or less depth, as its specific gravity is greater or less compared with the air through which it passes. However, M. Euler thinks the cause of the aurora borealis not owing to the zodiacal light, as M. de Mairan supposes: but to particles of our atmosphere, driven beyond its limits by the impulse of the solar light. And on this supposition he endeavours to account for the phenomena observed concerning this light. He supposes the zodiacal light, and the tails of comets, to be owing to a similar cause. But ever since the identity of lightning and the electric matter has been determined, philosophers have been naturally led to seek for the explication of aerial meteors in the principles of electricity; and there is now no doubt but most of them, and especially the aurora borealis, are electrical phenomena. Besides the more obvious and known appearances which constitute a resemblance between this meteor and the electric matter by which lightning is produced, it has been observed that the aurora occasions a very sensible fluctuation in the magnetic needle; and that when it has extended lower than usual in the atmosphere, the flashes

have been attended with various sounds of rumbling and hissing, especially in Russia and the other more northern parts of Europe; as noticed by Sig. Beccaria and M. Messier. Mr. Canton, soon after he had obtained electricity from the clouds, offered a conjecture, that the aurora is occasioned by the dashing of electric fire positive towards negative clouds at a great distance, through the upper part of the atmosphere, where the resistance is least; and he supposes that the aurora which happens at the time when the magnetic needle is disturbed by the heat of the earth, is the electricity of the heated air above it: and this appears chiefly in the northern regions, as the alteration in the heat of the air of those parts is the greatest. Nor is this hypothesis improbable, when it is considered, that electricity is the cause of thunder and lightning; that it has been extracted from the air at the time of the aurora borealis; that the inhabitants of the northern countries observe it remarkably strong, when a sudden thaw succeeds very cold severe weather; and that the tourmalin is known to emit and absorb the electric fluid only by the increase or diminution of its heat. Positive and negative electricity in the air, with a proper quantity of moisture to serve as a conductor, will account for this and other meteors, sometimes seen in a serene sky. Mr. Canton has since contrived to exhibit this meteor by means of the Torricellian vacuum, in a glass tube about three feet long, and sealed hermetically. When one end of the tube is held in the hand, and the other applied to the conductor, the whole tube will be illuminated from end to end, and will continue luminous without interruption for a considerable time after it has been removed from the conductor. If, after this, it be drawn through the hand either way, the light will be remarkably intense through the whole length of the tube. And though a great part of the electricity be discharged by this operation, it will still flash at intervals, when held only at one extremity, and kept quite still; but if, at the same time, it be grasped by the other hand in a different place, strong flashes of light will dart from one end to the other; and these will continue twenty-four hours or more, without a fresh excitation. Sig. Beccaria conjectures that there is a constant and regular circulation of the electric fluid from north to south; and he thinks that the aurora borealis may be this electric matter performing its circulation in such a state of the atmosphere as renders it visible, or approaching nearer than usual to the earth; though probably this is not the mode of its operation, as the meteor is observed in the southern hemisphere, with the same appearances as in the northern. Dr. Franklin supposes, that the electric fire discharged into the polar regions, from many leagues of vaporized air raised from the ocean between the tropics, accounts for the aurora borealis; and that it appears first where it is first in motion; namely, in the most northern parts; and the appearances proceed southward, though the fire really moves northward. Mr. Kirwan, in the Transactions of the Royal Irish Academy, anno 1783, has also some ingenious remarks on the aurora borealis and australis. He gives his

reasons for supposing the rarefaction of the atmosphere in the polar regions to proceed from them, and these from a combustion of inflammable air caused by electricity. He observes, that after an aurora borealis the barometer commonly falls, and high winds from the south generally follow. The only distinct history of this phenomenon is what we have from Dr. Halley, Philosophical Transactions, No. 347. Mr. Forster, who, in his voyage round the world with Captain Cook, assures us, that he observed them in the high southern latitudes, though with phenomena somewhat different from those which are seen here. On February 17th, 1773, as they were in the fifty-eighth degree of south latitude, 'A beautiful phenomenon,' says he, 'was observed during the preceding night, which appeared again this and several following nights. It consisted of long columns of a clear white light, shooting up from the horizon to the eastward, almost to the zenith, and gradually spreading on the whole southern part of the sky. These columns were sometimes bent sideways at their upper extremities; and though in most respects similar to the northern lights (auroræ boreales) of our hemisphere, yet differed from them in being always of a whitish color, whereas ours assume various tints, especially those of a fiery and purple hue. The sky was generally clear when they appeared, and the air sharp and cold, the thermometer standing at the freezing point.' These are what Mr. Kirwan denominates aurora australis.

M. Libes, in his *Nouv. Dict. de Physique*, has suggested a new theory, which is adopted by most of the northern philosophers. In his opinion electrical light is not the cause of the aurora borealis; nor has electricity itself any farther influence upon their existence than as it fixes the aeriform substances whose combinations occasion the meteor. This philosopher's theory is founded upon the following principles:—1. If we excite the electric spark in a mixture of azotic and oxygen gas, there will result nitric acid, nitrous acid, or nitrous gas, according to the relation that subsists between the gases which compose the mixture. 2. Nitric acid, when exposed to the sun, assumes more color and volatility. Scheele first observed this phenomenon. Libes placed a receiver over a salver containing nitric acid, and exposed to the action of the solar rays. Some minutes after, the acid appeared colored, and the receiver filled with red and volatile vapors, which were sustained in it a long while, and diffused a light similar to that of the aurora borealis. 3. In flasks, which contain nitrous acid, a ruddy and volatile vapor is always perceived above the vapor. 4. Nitrous gas, in contact with atmospheric air, exhales ruddy vapors, which fly off into the atmosphere. 5. The hydrogen, which is disengaged from the surface of the globe, rises till it occupies, in the higher regions of the atmosphere, a place determined by its specific gravity. 6. The solar heat has very little activity in the polar regions.

These principles rest upon observations and experiments made with the greatest exactness, and most of them too well known to need being described here. Now it is manifest from a simple combination of these facts:—1. That the

production of hydrogen must be almost nothing in the polar regions. 2. That the higher regions of the polar atmosphere contain very little if any hydrogen. 3. That whenever there is a re-establishment of equilibrium of the electric fluid in the polar atmosphere, this fluid can only find in its passage a mixture of azot and oxygen. 4. That the electric spark ought to fix and combine these gaseous substances. 5. That from this combination must result a production of nitrous acid, of nitric acid, or of nitrous gas, according to the relation subsisting between the oxygen and azot that constitute the mixture. 6. That the productions of either of these acids, or of the gas, will give birth to red and volatile vapors, whose elevation in the atmosphere will form the meteor known under the name of the aurora borealis.

After removing some general objections to these preliminary notions, M. Libes applies them to the phenomena below:

1st *Phenomenon*.—The auroræ boreales are sometimes accompanied by slight detonations.

In the polar regions, the production of hydrogen is next to nothing, by reason of the little activity of the solar heat. It is nevertheless true, that in summer the long duration of the sun above the horizon causes even there a heat sufficiently considerable to produce the disengagement of some small portion of hydrogen, which will rise up to the higher regions of the atmosphere: whence it results, that if the re-establishment of equilibrium of the electric fluid takes place in the polar atmosphere, when its superior strata contain this gaseous substance, the electric spark must exert upon it a part of its activity, and produce slight detonations.

2d *Phenomenon*.—The major part of auroræ boreales appear to move from the north towards the south; though some are seen whose motion is directed towards the east and west.

The nitric acid, nitrous acid, and nitrous gas, which give birth to auroræ boreales, have their origin towards the poles. These substances exhale ruddy vapors, which, as they rise in the atmosphere, must direct their motion towards the place where they meet with least resistance; which is, of course, towards the south, where the air, always less dense than about the north, offers them a more free and easy passage. It may also happen that at the same time these ruddy vapors are formed, a northerly wind may blow in the upper region of the atmosphere, and thus give them a strong impulsion, which, combined with the preceding general tendency southward, may cause a resulting motion to be sometimes southward, at others eastward, or westward.

3d *Phenomenon*.—The auroræ boreales sometimes exhibit themselves under the form of luminous columns having different figures and different directions. Some are cylindrical, others pyramidal, others are curved in the shape of an arc. When they are impelled with much activity, they proceed to the zenith of the spectator. Those whose motion is still more rapid, go on beyond the zenith, sometimes even till they reach the southern horizon. They do not always rise directly from the centre of the cloudy part to-

wards the zenith; but sometimes take a lateral direction, especially when the cloud from whence they spring is found suspended between the north and the east or west.

When the re-establishment of equilibrium of the electric fluid fixes and combines a great quantity of azote and oxygen, the ruddy vapors resulting from this combination must occupy a large space in the atmosphere. These vapors being of such considerable extent, and impelled from north to south, must sometimes separate from one another, the different portions receiving various directions; thus they will be carried sometimes perpendicularly, at others parallel to the horizon; at others parallel to the earth's axis; whence it follows that the aurora borealis must sometimes appear to the observer in the form of columns, whose number, figure, and direction, are determined by circumstances. It may also sometimes happen that these luminous columns remain for a time immovable with respect to the horizon. This ought to be the case whenever a wind impels the luminous cloud towards any part whatever from the south, with the same force as the exhalations are impelled towards it by a contrary wind.

4th *Phenomenon*.—The auroræ boreales do not all shine with an equally vivid lustre; some have a mild and tranquil light, others shine with a very resplendent brilliancy.

The vapors which are disengaged from nitric acid exposed to the solar rays, diffuse a mild light of a clear red, verging towards yellow; those which are perceived above them from nitrous acid, are of a deep red; those exhaled from the nitrous gas, in contact with the atmospheric air, are at first of a pretty deep red, which afterwards become more and more clear and light, as these vapors extend themselves more in the atmosphere. The luminous columns, therefore, presented by the aurora borealis, have different colors, according as the ruddy vapors take their rise from the formation of the nitric acid, of the nitrous acid, or of the nitrous gas. Retrospect of Philosophic, &c. Discoveries, No. 8. Our countryman, Mr. Dalton, is of opinion that the aurora borealis is a magnetic phenomenon, the beams being governed by the earth's magnetism. See his Meteorological Essays, and Gregory's Astronomical and Philosophical Lessons. See our article ELECTRICITY.

AURORA SURGENS, in alchemy, a phrase used to express the multiplicative virtue of the philosophers' stone.

AURUM, Latin, gold. See GOLD, CHEMISTRY, and METALLURGY. This metal was introduced into medicine by the Arabians, who esteemed it one of the greatest cordials and comforters of the nerves. From them Europe received it without any diminution of its character; in foreign pharmacopeias it is still retained, and even mixed with the ingredients from which simple waters are to be distilled. But no one, it is presumed, at this time expects any singular virtues from it, since it certainly is not alterable in the human body. Former chemists endeavoured, by many elaborate processes, to extract what they call a sulphur anima, or spirit of gold; but no method is as yet known of separating the com-

ponent parts of this metal: all the tinctures of it, and aurum potable, which have hitherto appeared, are real solutions of it in aqua regia, diluted with spirit of wine or other liquors, and prove injurious to the body rather than beneficial. A place, however, is now given in some of the foreign pharmacopœias to the aurum fulminans; and it has been recommended as a remedy in convulsive diseases, particularly in the chorea sancti viti.

AURUM FULMINANS is a dangerous preparation, and should be used with great caution. A scruple of this powder acts more forcibly than half a pound of gunpowder: a single grain laid on the point of a knife, and lighted at a candle, goes off with a greater noise than a musket. Dr. Black attributes the increase of weight, and the explosive property of this powder, to adhering fixable air. See **CHEMISTRY**, Index.

AURUM MOSAICUM, **AURUM MUSIVUM**, a preparation so called from its golden color, made of mercury, tin, sal ammoniac, and flowers of sulphur. It is recommended in most chronic and nervous cases; and particularly convulsions of children. Its dose is from four grains to a scruple. It is also used as a pigment, and for mixing with glass, to imitate the spangles of the lapis lazuli. Mosaic gold is composed of 100 tin + 56.25 sulphur, by Dr. John Davy; and of 100 tin + 52.3 sulphur, by Professor Berzelius; the mean of which, or 100 + 54.2 is probably correct. It will then consist of 1 prime of tin = 7.375 + 2 sulphur = 4.0.

AURUM POTABILE, or tincture of gold; a medicine formerly in great request, but at present rarely used. It is prepared by mixing essential oil of rosemary with a solution of gold in aqua regia; and after slaking the vessel, the gold is retained in the oil, swimming on the top. The very name imposes on many people, and gives an opportunity to empirics to cheat them; for they draw tinctures from ingredients whose colors come near to that of gold, and sell them at an exorbitant rate under this title. This sort of deceit generally succeeds best; for patients are prepossessed in favor of such medicines as cost much, carry great names, and have a specious appearance. It often happens that these tinctures produce some good effects, because they can make them with such spirituous menstrua, as comfort the patient, and expel humors by perspiration; then the effect is extolled for a miracle, and attributed to the imaginary gold.

AURUM REGIÆ. See **QUEEN-GOLD**.

AURUM SOPHISTICUM, mimic gold, a chemical preparation made as follows: take fine distilled verdigris, eight ounces; crude Alexandrian tutty, four ounces; borax, twelve ounces; salt-petre, one ounce and a half; pulverise and mix them all together, tempering them with oil to the consistency of a plaster; then put a German crucible into a wind furnace, heat it red hot, and putting your mass into it, let it be covered, and the furnace filled with coals over the crucible. When the mass is melted, let it cool of itself, then break the crucible, and you will find at the bottom a fine regulus, like gold, weighing about four ounces, which being malleable may be wrought into any form.

AURUM VEGETABILE, Saffron.

AURUNCI, in ancient geography, a people of Latium, towards Campania; the same with the Ausones, at least so intermixed as not to be distinguishable, though Pliny makes a distinction.

AURUNGABAD, (so called from the Mogul Emperor Aureng-zebe), a province of the Deccan, Hindostan, principally divided between the Mahrattas and the Nizan; the former possessing about three-fourths of its area, and strictly including the islands of Salsette and Bombay, belonging to the British. It is bounded on the north by Gujerat, Candesh, and Berar; on the east by Berar and Hyderabad; south by Bejapoor and Boeder; and west by the ocean; its length being about 300 miles, and its average breadth 160 miles. Although this province is hilly throughout, it gives rise to no rivers of consequence. The Beemah and Godavery, which have their sources in the same neighbourhood (about thirty miles east of Poonah), are the principal streams. On the banks of the former are reared the strongest Mahratta horses, called the Beemarheddy breed, and the whole province is fertile, particularly in rice. Its natural fastnesses have been in numerous places fortified by art; and under the warlike dominion of the Mahrattas have been rendered at once the security and curse of the country. These fortresses are principally occupied by independent chieftains, who pay a sort of feudal homage to the Paishwa, but are in reality the lords of the soil. The population is about six millions, consisting mainly of Brahminical Hindoos. Ahmednuggar, Aurungabad, Basseen, Damaura, Dowletabad, and Jalnapoor, are the chief towns. In the article **AHMEDNUGGAR** it will be seen that an independent sovereignty of that name, which included the greater part of this province, was established here at the close of the sixteenth century. A few years afterwards (1601 to 1630), we find the province called by the name of another principal town, Dowletabad, the seat of the Nizam Shahee dynasty, which being taken in 1634 by the Moguls, the government was transferred to Gurka, the former name of the city of Aurungabad. The East India Company's forces at Bombay command the whole of the coast, which swarms with native pirates. See **AHMEDNUGGAR**.

AURUNGABAD, the capital of the above district, was, under its original name of Gurka, the chief town of the viceroyalty of the Deccan, and the residence of the emperor Aureng-zebe, while viceroy: a circumstance to which it owes, with the province, its present name. It continued to be the capital of a Mogul soubah until the Nizams withdrew their allegiance from the court of Delhi; it was then for some years the capital of the Nizam's dominions. At present, the capital having been transferred to Hyderabad, Aurungabad is on the decline; but there is a noble bazaar here for shawls and silks, and a fine ruin, once the palace of Aureng-zebe. The Fakeer's tomb is also admired. It is distant from Poonah 186 miles, and 284 from Bombay. Lat. 19° 46' N., long. 76° 3' E.

AUSA, a town of Tarraconensis, in the middle age called Ausona, now Vich de Ossona, a town of Cataonia in Spain.

AUSCH. See AUCH.

AUSCI, a people of Gaul, the ancient inhabitants of AUCH. See AUGUSTA.

AUSCULTATOR, in ancient customs, a person appointed in monasteries to hear the monks read and sing, and to instruct them how to perform, before they were admitted to read or chant publicly in the church.

AUSHOFEN, a town in the circle of Suabia, belonging to the house of Austria. Long. $27^{\circ} 16' E.$, lat. $48^{\circ} 15' N.$

AUSI, or AUSENSE, an ancient and very savage people of Libya. Herodotus tells us that they were unacquainted with marriage, and had all their women in common. The children were brought up by their mothers till they were able to walk; after which they were introduced to an assembly of the men, who met every three months; and the man to whom any child first spoke, acknowledged himself its father. They celebrated annually a feast in honor of Minerva, in which the girls divided into two companies, and fought with sticks and stones; those who died of their wounds were concluded not to have been virgins.

AUSIMUM, or AUXIMUM, an ancient Roman colony in the Picenum; now Osimo or Osmo, in Ancona.

AUSITÆ, AISITÆ, or ÆSITÆ, a tribe of ancient Arabs, supposed by Bochart to have inhabited the land of Uz mentioned in Job. See ARABIA.

AUSKERRY, 1. a district in the island of Stronsay, consisting of four holms; 2. a small pasture isle belonging to the parish, and three miles from the island of Stronsay; and on which there are the ruins of an old chapel, and of a house called the Monker, or Monk's house.

AUSONA, in ancient geography, a town of the Ausones.

AUSON, a son of Ulysses and Calypso, from whom the Ausones are descended.

AUSONES, or AUSONI, a people who anciently occupied all the Lower Italy, from the Promontorium Circaum, down to the straits of Sicily, but were afterwards reduced to a much narrower compass; viz. between the Montes Circaei and Massici: nor did they occupy the whole of this, but other people were intermixed.

AUSONIA, the ancient name of Italy, from its earliest inhabitants the Ausones.

AUSONIUM MARE, in ancient geography, a part of the Ionian sea, extending southwards from the promontory Japygium, to Sicily, which it washes on the east, as it does the Brutii and Magna Græcia on the south and east. It is separated from the Tuscan sea by the straits of Messina.

AUSONIUS (Decius, or Decimus Magnus), one of the best poets of the fourth century, was the son of an eminent physician, and born at Bourdeaux. Great care was taken of his education, either because his genius was very promising, or that the scheme of his nativity, which had been cast by his grandfather, made them imagine that he would rise to great honor. He made an uncommon progress in classical learning; at the age of thirty he was chosen to teach grammar at Bourdeaux; and afterwards pro-

moted to be professor of rhetoric; in which office he acquired so great a reputation that he was sent for to be preceptor to Gratian, the emperor Valentinian's son. He was afterwards appointed consul, by his pupil Gratian, then emperor, A.D. 379; and besides the dignity of questor, to which he had been nominated by Valentinian, he was made prefect of the Prætorium in Italy and Gaul, after that prince's death. His speech, returning thanks to Gratian on his promotion to the consulship, is highly commended. He lived to a great age. The emperor Theodosius had a great esteem for him, and pressed him to publish his poems. There is a great inequality in his works, and in his style there is a harshness which was perhaps rather the defect of the times he lived in, than of his genius. According to Lempriere, he did not take proper time to correct his poems, but hurried them to publication, which may be the cause of many faults. One valuable performance, the Consular Fasti, is now lost. He is generally supposed to have been a Christian. The best edition of his poems is that of Amsterdam, in 1671. They were printed at Paris, with a French translation, in 1769.

AUSPEX, a name originally given to those who were afterwards denominated augurs. It is formed from *avis*, a bird, and *inspicere*, to inspect; auspices, *q. d.* avispices. Some will have auspices only to denote those who foretell future events from the flight of birds.

AUSPICATE, *v. & adj.* } Lat. *aruspex*, from
AUSPICE, } *avis*, a bird, the ob-
AUSPICY, } solete *spicere*, to
AUSPICIOUS, } look; to take fa-
AUSPICIOUSLY. } vorable omens from
birds; but in a less formal and official manner than by augury. To foretell good fortune, prosperity, &c. Auspicious is synonymous with favorable, prosperous.

Know thus far forth;

By accident most strange, bountiful fortune
(Now my dear lady) hath mine enemies
Brought to this shore, and by my prescience
I find my zenith doth depend upon

A most auspicious star; whose influence
If now I court not, but omit, my fortunes

Will ever after droop. *Shakspeare. Tempest.*

None of their kindred met; the knot they ty

Silent; content with Brutus auspicy.

May's Lucan, book ii.

Thus were their loves auspiciously begun,

And thus with secret care were carried on.

Dryden's Fables.

Skilled in the wing'd inhabitants of air,
What auspices their notes and flight declare
O! say—for all religious rites portend
A happy voyage and a prosperous end. *Dryden.*

But so may he live long, that town to sway,

Which by his auspice they will nobler make,

As he will hatch their ashes by his stay. *Id.*

AUSPICUM, AUSPICY, the same with AUGURY. Servius, indeed, distinguishes between auspicy and augury; making auspicy comprehend the consideration of all things; augury only of certain things.

AUSPITZ, a town of Moravia, in the circle of Brunn, belonging to the prince of Lichtenstein. Here are held large cattle markets which

are attended by a number of graziers from Hungary. Population 2215. Forty-two miles S.S.W. of Olmutz.

AUSTER, one of the four cardinal winds, as Servius calls them, blowing from the south.

AUSTERIE, } Lat. *austerus*; from *avo*,
AUSTERE'LY, } I dry; because harsh taste;
AUSTERE'NESS, } dry the palate. Harsh, dis-
AUSTER'ITY. } agreeable to the moral taste,
rigorous, severe.

My unsoil'd name, th' *austereness* of my life,
May vouch against you; and my place i' th' state
Will so your accusation overweigh. *Shakspeare.*

Now, Marcus Cato, our new consul's spy,
What is your sour *austerity* sent t' explore?

Ben Jonson.

What was that snaky-headed Gorgon shield
That wise Minerva wore, unconquer'd virgin,
Wherewith she freez'd her foes to congeal'd stone,
But rigid looks of chaste *austerity*,
And noble grace, that dash'd brute violence
With sudden adoration and blank awe? *Milton.*

Th' *austere* and pond'rous juices they sublime
Make them ascend the porous soil, and climb
The orange tree, the citron, and the lime.

Blackmore.

Compos'd in gait,
Austerely grave and thoughtful, on his shield
The democratic majesty he bore
Of Athens. *Glover's Leonidas*, book vii.

AUSTERE implies also rough or astringent. Thus an austere taste is such a one as constricts the mouth or tongue; as that of unripe fruits, harsh wines, vitriol, alum, &c. Austere substances, says Mr. Chalmers, differ from acerb ones, in that they constrict the mouth and tongue less, and are void of acidity.

AUSTERLITZ, or STAWKOW, a small town of Moravia, in the circle of Brunn, twelve miles east of Brunn, belonging to the prince of Kaunitz Rielberg. Population about 1620. This town will be long memorable in history for the great battle fought near it on the 2d of December, 1805, the anniversary of Buonaparte's coronation, between the French under him, and the united forces of Austria and Russia, under their respective emperors. The armies it appears were nearly equal, being about 70,000 men each. Buonaparte, by feigning a retreat, drew the allies to a spot which he had selected for giving battle; and he bivouacked on the field, after having spent most of the night in giving orders. The battle commenced with the dawning light. After a cannonade of several hours the allied right and centre were routed; and their left, which had been successful in the outset, was compelled to give way. The defeat was signal; but the approach of night prevented pursuit; the state of the roads compelled the allies to abandon most of their artillery, and forty standards; all the baggage and ammunition of the allies, and 1200 pieces of cannon, remained in the hands of the French. The French are supposed to have lost 43,000 men in killed and wounded; and the Austro-Russian three times the number. It is certain that so many wounded were left on the field by the allies, that they could not all be dressed until two days after the battle. Near this place an interview immediately took place between the emperor of Austria and Buonaparte, in

a mill, and the preliminaries of an humiliating peace were agreed to. But the emperor Alexander refused to become a party to it, and succeeded, though under every difficulty, in effecting his retreat homeward.

AUSTIN (William), an English author, was a barrister of Lincoln's Inn. He wrote a book entitled *Hæc Homo*, or the Excellency of Women, 12mo.; in which he seems to have borrowed very freely from Agrippa's *De Nobilitate at Præcellentia Fœminei Sexus*. He wrote also *Meditations on the principal Fasts and Feasts of the Church*, which were published in folio, 1637, after his death.

AUSTIN (St.) See AUGUSTINE, St.

AUSTRALASIA, or AUSTRALIA, is a new and fifth great division of the globe, originally suggested by a learned foreigner, M. le President de Brosses of Paris; but whose principal parts have been explored by Englishmen, and which has been colonised solely from this country. It comprehends a tract of ocean, bounded on the north by the equator, east by a line drawn on the 186th degree of east longitude, to the 55th degree of south latitude, south by the 55th parallel, and west by a line drawn from the north-west Cape of Ilapau, on the east of the islands of Mysol, Timorlaut and Ceram, to the 65th degree of east longitude on the 55th parallel; making an irregular four-sided figure, extending upwards of 5000 miles in average breadth from east to west, and about 3200 miles from north to south.

Australasia is, therefore, a maritime division of the globe, in distinction from the older terrene divisions of Europe, Asia, Africa, and America; it is, altogether, a classification of islands, having no one continent of this name, including, as the other divisions of the world, various kingdoms circumscribed by one shore; so far it is an anomaly in geographical classification. 'But in this immense extent of regions, which are to form the object of researches about to be detailed,' says M. de Brosses (*Histoire des Navigations aux Terres Australes*), 'how numerous are the different countries, climates, manners, and races of mankind! The sight would be dazzled and confounded if care were not taken to relieve it, and fix its attention, by divisions marked from distance to distance.' On these grounds he proposed, together with a classification of the islands of the Pacific, under the name of Polynesia, to include New Holland, New Guinea, New Zealand, and the islands in their neighbourhood, under the collective name of Australasia, an arrangement that has been latterly adopted by most respectable writers. Some have preferred the term Australia, as more consonant to the primitive appellation, Terra Australis, or Southern Land.

The progress of the discovery of this immense region may be correctly united, with the common features of its various parts, under this collective article. The history of particular settlements will be found under BOTANY BAY, NEW HOLLAND, NORFOLK ISLAND, VAN DIEMEN'S LAND, &c. in their alphabetical positions in our work. We present the reader with a Chronological Table of the discovery of the islands of Australasia.

A Chronological Table of the discovery of the Islands of Australasia.

NAME.	WHEN DISCOVERED.	BY WHOM.	INHABITANTS.
1. Papua or New Guinea.	1526.	The Portuguese, under D. Jorge de Meneses.	Black Negroes; much resembling those of Guinea.
2. New Holland,	Supposed to be uncertain— Marked in a Map in the British Museum in 1542; first authentic account of its being visited, dated 1606.	The Dutch, in the Duyxten yacht. About the same time the Spaniards visited it under Torres, and F. de Quiros.	Ditto; a remarkably barbarous race;—all of them of the most unpleasant look, and the worst features of any people I ever saw, though I have seen a great variety of savages, says Dampier.
3. Solomon's Islands. Of which the principal are— Buonavista, Florida, Galera, Guadalcanar, Santa Ysabel, San Christoval, San Catarina, Santa Ana,	1567.	The Spaniards, under Alonso de Mandana. Not again visited until by Carteret, in 1767.	Inhabitants, cannibals. — Many of the islands very fertile. Extend from S. lat. 5° to 11°, E. long. 155° to 162° 30'.
4. New Hebrides, According to Cook, Tierra des Espiritu Santo, St. Bartholemew, Mallicola, Isle of Lepers, Aurora, Whitsuntide, Amtrym, Apee, Paoom, Three Hills, Sandwich, Montagu, Hichinbrook, Shepherd's Isles, Erromango, Tanna, Inner, Annatom, Erronan,	1606.	The Spaniards, under F. de Quiros, and L. V. de Torres.—Explored by Captain Cook in 1774, who gave them their present name.	Inhabitants, more civilized, at Tanna the negro character disappears. The country very fruitful and agreeable; and, in some of them laid out in well fenced plantations. The Terra del Espiritu Santo, the principal of the group, lies in S. lat. 14° 30', E. long. 167° 30'.
5. New Britain, New Ireland, &c.; a group not fully ascertained. To the N. W. are the Admiralty Isles.	1616.	The Spaniards, under Le Maire and Schouten.	Inhabitants of New Britain and Ireland black negroes. Inhabitants of the Admiralty Isles of a lighter color, and approaching the Malay character. All the islands fertile and well watered: lying in a crescent, whose centre lies in S. lat. 50°, E. long. 150°.
6. Van Diemen's Land.	1642— as an island in 1798.	The Dutch, under Abel Jansen Tasman.—The British, Capt. Flinders and Mr. Bass.	A similar race. Called after the Dutch governor of the East Indies, Anthony Van Diemen.
7. New Zealand, having to the east Chatham Island.	1642. Chatham island in 1791.	The Dutch, under Abel J. Tasman.—By Mr. Broughton when with Vancouver.	Inhabitants remarkably strong, active, and barbarous. Have at the same time singular traces of civilisation amongst them.

A Chronological Table of the Discovery of the Islands of Australasia—continued.

NAME.	WHEN DISCOVERED.	BY WHOM.	INHABITANTS.
8. St. Paul and Amsterdam	1696.	The Dutch, under Vlaming.	Uninhabited. Amsterdám a volcanic production, if not the crater of an immense volcano, scarcely cool, and abounding with hot water springs. Seals are caught on the shore in large quantities.
9. Kerguelen's Land, or Island of Desolation			1772.
10. New Caledonia.	1774.	The British, under Capt. Cook.	Inhabitants, affable, honest, and of light complexion. The country comparatively barren, occasionally laid out in plantations.

We have thus exhibited the leading features of this extensive division of the globe, in the order in which they became known to Europe; but must not omit to notice the coral reefs and islets with which the Australasian seas abound. These are seen in every league of sea, and according to Dalrymple, in 'all stages' of their formation. Capt. Flinders, who was wrecked on one of them, conjectures, 'that when the animalculæ, which form the coral at the bottom of the ocean, cease to live, their structures adhere to each other, by virtue either of the glutinous remains within, or of some property in salt water; and the interstices being gradually filled up with sand and broken pieces of coral washed by the sea, which also adhere, a mass of rock is at length formed. Future races of these animalculæ erect their habitations upon the rising bank, and die in their turn, to increase, but principally to elevate, this monument of their wonderful labors.' It is pretty well authenticated that these submarine laborers uniformly build the outer part of their erection perpendicularly from the very bottom of the deepest seas. As it rises to the surface, and out of the water, salt plants, vegetable matter of various descriptions, floating wreck and other accumulations attach themselves to it; 'we had wheat-sheafs, mushrooms, stag's horns, cabbage-leaves, and a variety of other forms, glowing under water,' says Capt. Flinders, 'with vivid tints of every shade betwixt green, purple, brown, and white.' The dung of birds and the various seeds and other food they occasionally scatter, are fruitful sources of the growth of these extraordinary productions of the deep; some are seen considerably below the water, others just appearing above its surface; some as barren rocks with no indications of soil; others with a thin layer of earth, or a few weeds on the highest part; and others, again, well clothed with soil and even with timber. The recent navigator of these seas, whom we have quoted, describes himself as having to seek fourteen days, and sail upwards of 500 miles amongst that range of these reefs and islets which environs the eastern coast of New Holland, before he could find a passage through them to the open sea.

In no part of the globe can greater extremes of barrenness and fertility occur than in the various islands comprehended in Australasia. On the shores of New Holland, its most prominent feature, we find fruitful plains covered with verdure eastward, and on the south and south-western coast nothing but naked hillocks of sand; 'so uniform,' says M. D'Enticasseaux, 'that the most fruitful imagination could find nothing to say of it.' This island, indeed, if such it is to be called, almost equal in size to the whole of continental Europe, presents of itself an unequalled and almost unexplored field for geological enquiry; the outline of the western coast is not filled up; and some recent journeys into the interior, from our colony on the eastern shore, have disclosed an extensive series of as promising lands, watered by some noble rivers, within 140 miles of Sidney, as are found in any part of the world. See NEW HOLLAND.

The natives of Australasia are for the major part, of a decisively African or negro character; and nowhere is human nature found in a more degraded state. An enormous head, flat countenance, and long, slender extremities, mark their physical conformation, together with an acuteness of sight and hearing; but, often half-starved, their strength is generally less than that of the inhabitants of other climes. In no part of these seas is the population great. Not more than 20,000 inhabitants have been seen on all the coasts of these islands taken together. Of natural affections, little, of course, appears, and of religion, absolutely nothing. Mothers have scarcely the regard of the brute creation for their offspring. They will commonly procure abortion by violent means; and sometimes adopt the horrible expedient of burying their children alive, to be freed of the trouble of them. An inhabitant of New Holland knocks down the woman of his choice with a club, in the presence of her friends, and takes her into the woods, while in a state of insensibility. Here the alliance is preserved as long as he finds it convenient; he then deserts her for a new wife, who is similarly obtained.

No quadrupeds larger than the kangaroo are found here, and none whatever in many of the

AUSTRIAN DOMINIONS.

English Miles.

0 20 40 60 80 100

Longitude East 16 from Greenwich

islands. This animal was first described by Captain Cook, who found it while with a shooting party on the coast of New South Wales in 1770. It is peculiar to this part of the world, but has been found to breed well in England. There is also a small animal peculiar to Australasia, called the wombat, of the bear tribe, but remarkably tame. The most extraordinary animal, however, of this, or perhaps of any other region, is the ornithoryneus paradoxus, or duck-bill; a quadruped with the beak of a duck. Dr. Shaw was so astonished at this apparent mixture of bird and quadruped in its formation, that when the first specimen was exhibited to him at the British Museum, he suspected it to be an attempt at imposition. 'Nor is it without a minute examination,' says this distinguished naturalist, 'that we can persuade ourselves of its being the genuine snout of a quadruped. The body is depressed, and has some resemblance to that of an otter in miniature; it is covered with a very thick sort of beaver, like fur, and is of a moderately dark brown color above, and of a sub-ferruginous white beneath, with some variety as to intensity of color in different animals. The head is flattish, and rather small than large; the tail flat, furry, like the body, rather short and obtuse, with an almost bifid termination; it is broad at the base, and gradually lessens to the tip. The general length of the animal, from the tip of the beak to the end of the tail, seems to be from thirteen or fourteen, to eighteen inches. The legs are very short, terminating in a broad web, and claws which on the fore feet are five in number, straight, strong, and pointed; but on the hind feet in the male, are six claws, the sixth or interior one being seated much higher up than the rest, and resembling a long sharp spur.' Dr. Shaw first described this animal in his Naturalist's Miscellany, under the title of *Platypus animus*.

Numerous tribes of beautiful birds are seen here. The bird of Paradise, so long spoken of in Europe as wanting feet; paraquets, cockatoos, a singular species of cassowary, and a black swan. Immense whales, seals, and dolphins, crowd upon the shores, where a large cuttle fish is sometimes seen, having the appearance of a cask upon the water, and stretching out its tentacula to the length of seven or eight feet. The tribe of molluscas is also singularly rich. One species of marine fucus has been found to reach from the bottom of the sea to the surface, on a stem from 250 to 300 feet in length.

The botany of this region is as curious and novel as any other of its features. Mr. Brown,

who accompanied Captain Flinders, and who had the magnificent botanical collections of Sir Joseph Banks under his charge, has arranged a Flora Terræ Australis, containing 4,200 species referable to 120 natural orders, eleven of those orders containing about half the species. In Van Dieman's Land, the gum-tree (of which 100 different species are found) not unfrequently attains the height of 150 feet, with a girth near the base of from twenty-five to forty feet. The gum of this tree is medicinal, and that of one species makes very good pitch. It also furnishes, together with the sasuarina, excellent timber for ship-building, agricultural implements, or domestic furniture.

There can be no question that the supposed existence of an immense continent in the Southern Ocean first invited the navigators of the sixteenth and seventeenth centuries to explore these important islands; nor was the idea of its existence wholly abandoned until the discoveries of Captain Cook. The name of Terra Australis Incognita was given to this feature of science; and upon no point were geographers more agreed than respecting its existence, although its limits were variously defined. Even in the year 1770, 'the great southern continent' was declared by Mr. Dalrymple, in his Historical Collections, to be no longer a matter 'for discovery'; that 'it extended from 30° south, to the pole; and that the number of its inhabitants was probably more than 50,000,000;' while 'the countries intermediate' between the east and west points, 'equal in extent all the civilised part of Asia, from Turkey to China inclusive.' Thus the supposed extension of the East Indies round to the west, allured Columbus to the arduous enterprise that resulted in the discovery of the western world; and thus some harmless errors, pursued with humility, are kindly allowed by providence to lead us to truth.

AUSTRALIS CORONA. See CORONA AUSTRALIS.

AUSTRALIS PISCES, the Southern Fish, is a constellation of the southern hemisphere, not visible in our latitude: whose stars, in Ptolemy's catalogue, are eighteen, and in the Britannic catalogue, twenty-four.

AUSTRALIZE. From *austrer*, the south. To point towards the south.

Steel and good iron discover a verticity, or polar faculty; whereby they do septentriate at one extreme, and australize at another. *Brown's Vulgar Errors.*

AUSTRASIA, the ancient name of, 1. Lorraine, in France; and, 2. of Westrick, in Germany.

A U S T R I A .

AUSTRIA, in geography, a country of Germany, the Upper Pannonia of the ancients, deriving its modern name from the French and Italian pronunciation of *Æsterich*; in High German, *Æsterreich*; a name which signifies the eastern kingdom, alluding to the geographical position of the province with respect to the more western parts of Germany, and which was originally applied to the circle of Austria, the patrimonial possession of the first grand dukes.

The CIRCLE OF AUSTRIA is the largest of the ten circles or divisions of the German empire, bounded on the east by Hungary, south by Italy and Croatia, west by Switzerland, and north by Suabia, Bohemia, and Moravia. It comprehends Austria Proper, Styria, Carinthia, and Carniola dutchies, the country of Tyrol, the principalities of Brixen and Trent, part of Friuli and the Littoral, Vorarlberg, certain districts in Suabia, and several domains belonging to the

Teutonic order; together with Salzburg and part of Passau, which have been added since 1802. Of this extensive circle, the four general divisions of Upper Lower, Anterior, and Interior Austria have been formed, corresponding with their administration by the chancery at Vienna; the whole including an area of 29,940 square miles, and a population of nearly 5,000,000.

The ARCHDUCHEY OF AUSTRIA, otherwise called Austria Proper, or the Hereditary States of the house of Austria, forms the upper and lower divisions of this circle, into which it is divided by the flowing of the river Ens. It is bounded on the north by Bohemia and Moravia, on the east by Hungary, on the south by Styria, and on the west by Salzburg and Bavaria, comprehending an area of 15,392 square miles, and a population of nearly two millions of inhabitants. Of the two divisions of this archduchy, Lower Austria is the most important, containing, on a surface of 7788 square miles, thirty-eight cities, 241 towns, 4327 villages; and by the last census, 1,100,000 inhabitants. It is made to consist of four subordinate divisions, lying upon the two opposite banks of the Danube. On the south bank the quarter 'above the forest of Vienna,' and 'the quarter below the forest of Vienna.' On the north bank the quarter 'above the Mannhartsberg,' and 'the quarter below Mannhartsberg.' Upper Austria, containing an area of 5104 square miles, and including fourteen cities, ninety-two towns, 6411 villages; and, according to the late census, 629,945 population; is also divided into four subordinate territories, those of

the Trann, Hansruck, and Inn, on the south bank of the Danube, and that of Muhl on the north. The archdukes of Austria were originally exempt from the jurisdiction of the high courts of the empire, took precedence of princes of the blood, and had the power of creating counts, barons, and other nobility. According to the Pragmatic sanction of 1713, the succession to this archduchy is hereditary, females not excluded. The revenue is about 24,000,000 florins, 20,000,000 of which are contributed by the country below the Ens. The states, however, assemble but seldom, and have but a very contracted influence in the management of national concerns.

The EMPIRE OF AUSTRIA, besides the provinces of the same name, including the archduchy and other territories described above, comprehends many ancient kingdoms and states which were originally independent. It is situated in the middle of eastern Europe, and is bounded by Piedmont, Switzerland; and Bavaria, on the west; Bavaria, Silesia, and Poland on the north; Russia, Moldavia, and Wallachia, on the east; Turkey, the Adriatic, and Middle Italy on the south. The northern part of the empire stretches into Bohemia, and the southern into the territory of Cattaro, in the region of Dalmatia. It has received several augmentations of territory at different periods, and includes a number of nations, all differing in their lineage, customs, languages, and habits, but forming one solid and compact political body, and subsisting at present under one general name.

The following table presents a view of its great component parts, as settled by the last peace, or in 1816:—

COUNTRIES.	Square Miles.	Inhabitants.	Computed Revenue in Sterling Money.
Circle of Austria	45,760	4,222,700	£4,000,000
Salzburg, Berchtolsgade, and Passau	4,378	255,000	140,000
Bohemia	20,900	3,112,000	2,000,000
Moravia	10,296	1,364,000	700,000
Austrian Silesia	1,826	286,000	150,000
Galicia, with the Bukowine	53,400	4,934,000	1,600,000
Hungary, including Transylvania, Sclavonia, and Austrian Croatia }	130,920	9,400,000	1,800,000
Venetian territories, including Istria	15,136	} 2,894,000	1,500,000
Dalmatia, with Cattaro, Ragusa, and the islands	8,052		
Lombardy, viz. the territories of Milan and Mantua	4,400	1,350,000	400,000
Lordships of Valtellin, Bormio, and Chiavenne.	1,320	108,700	20,000
Total in round numbers	300,000	28,000,000	12,000,000

In 1818, Mr. Liechtenstein states the extent of the empire, exclusively of the dependent states, at 250,000 square English miles; and the population at 28,297,382.

The natural features of Austria are very magnificent: the southern parts highly romantic; the seas and landscapes of Carinthia, Carniola, and Dalmatia, have long been celebrated as some of the most perfect in the Alpine regions;

whilst detached hills and chains of mountains bulge in irregular figures all over the northern districts, uniting themselves with the great Carpathian chain, the natural boundary of Hungary and Transylvania. But the Tyrol stands pre-eminent for its rich variety of picturesque scenery. Bold mountains and defiles, lakes and glaciers, cataracts and cascades, rivers, woods, and valleys, shaded with great beauty, bestowed in the

different grounds of the picture, irregularly grouped and brought, unite in the same sweep of prospect, and overwhelm the mind of the spectator with unutterable emotions.

The highest mountains belong to the central part of the empire; namely, to Styria, Carinthia, and Carniola, where they frequently reach the height of 4000 feet. The snowy mountain, in the hereditary states, is of vast altitude, and may be seen from the ramparts of Vienna every clear day. The elevated ramifications of the Alps and Carpathian mountains, with the circular barrier of Bohemia and other ranges, spread themselves over very extensive regions of the Austrian empire, and under various names and forms stretch from the borders of Switzerland to the confines of Russia.

The interior of Austria is intersected by noble rivers. The Danube is altogether, perhaps, the most rapid and majestic. This river, winding its course from the north-west to the south-east, divides the whole empire into two distinct parts. It receives into its bosom upwards of forty tributary streams before it enters the Austrian dominions, and afterwards an accession of one hundred more before it enters the Euxine Sea. The rivers that empty themselves into this grand emporium of waters are many of them of considerable magnitude, and chiefly take their rise in the mountains already enumerated. The Thesis originates in the eastern part of the Carpathian range, and is at first a fine, clear, and rapid stream. It flows four degrees east longitude, and then turning south, crosses Hungary, receiving the Maros, Koros, and other tributary accessions, and enters the Danube near the city of Belgrade. The river Save is formed by numerous mountain torrents descending from the summits of Tyrol. It flows along the southern border of the Austrian dominions, and enters the Danube a little below the Thesis. The Drave originates in the streams and cataracts of the mountains of Carinthia, and receives the Muhr at Legrad, which conveys the waters from the northern summits of Styria. Crossing these two beautiful provinces, and forming the separating boundary between Croatia and Hungary, it falls into the Danube below Esseeck. The Inn, rising in the elevated regions of the Swiss Alps, and descending to the north-east through the kingdom of Bavaria, forms the western boundary of the empire, and enters the Danube at Passau. The Raab and Leytha rise in the western parts of Hungary, and fall into the Save; the former near Komora, and the latter at Presburg. The Morava, or March, from which Moravia derives its name, descends from the northern extremity of that province, and proceeding south, falls into the Danube west of Presburg. The Mulda rises in the southern regions of Bohemia, and taking a northerly direction, flows into the Elbe. The southern parts of Austria are watered by numerous important streams and rivers, which originate in the chain of mountains that encircles the north of Italy, are cherished by the overflowings of those lakes that lie upon its bosom, and are poured over the summits of that lofty range in falling torrents and beautiful cascades.

The Adige and the Po will be described in our view of Italy. The Piave rises in the overflowings of the sub-alpine lakes, and descends through the territory of Brixen and the province of Treviso, into the Gulf of Venice. The Tesino rises in St. Gothard mountain, and forms the south-western boundary of the Austrian territory, flowing through the country of Grisons, the lake of Maggiore, and the Milanese territory; it washes the walls of Pavia, and falls into the Po. The Adda rises in Mount Braulio in the country of the Grissons, and after flowing through the valley of Valteline, falls into the lake of Como, and re-issuing from the south-east arm of that basin, enters the Po near Cremona. The Oglio rises in the Val Camonica, and bending to the south, flows through Venice and lake Isero to the duchy of Milan, and then winding south-east, crosses the duchy of Mantua, and falls into the Po a few miles east of the Adda. The greater part of the Austrian rivers are too rapid, and too much impeded by rocks and waterfalls, to admit of any extensive navigation; much, however, has been effected by canals, and plans of the most gigantic kind have been formed for connecting the great rivers with each other, and thus opening a communication between the interior of Austria and all the maritime kingdoms of Europe.

The lakes of Austria are numerous, but are inferior to those of Russia and Switzerland. They chiefly lie upon the tops of mountains, or pent up within the valleys and intersections formed by the bold ridges which characterise the scenery. Those on the south side of the great Alpine range are considered among the grandest specimens of picturesque beauty found in Europe. They form the distinguishing features of the landscape, and furnish that delightful charm which so bewilders and astonishes the traveller. The chief are Maggiore, or Lucarno, Lugano, Como, Lecca, Iseo, and Garda. Maggiore is, from its situation and figure, regarded as the most beautiful. It lies embosomed in hills, adorned with orchards, nurseries, and vineyards, and has its summit shaded with dark thick forests of chestnut-trees. The banks are spotted with covered avenues in trellis-work, and are laid with numerous small sheets of water, while the lake itself presents a clear greenish surface, broken by beautiful islands of different figures and dimensions, embellished with numerous temples and gardens. Lake Como is almost equally delightful. It lies among mountain scenery perfectly romantic, and is celebrated for an intermitting spring near Tarno and the ancient Caves of Verena. The lake Lago di Garda is diversified with small islands, capes, promontories, and peninsulas, and lies sunk in hills richly adorned with vines, lemon, orange, olive, and other fruit-trees. On a peninsula of that lake lies the ancient ruins of Sirmis, so highly celebrated by Catullus. The small, but beautiful Iseo, is less than the other lakes, but lies amid the same alpine summits, and participates of the same delightful scenery.

The climate of Austria is various, and in general salubrious, except in the neighbourhood of the plains and marshes where the miasma often

proves fatal. In the southern regions it is warm, and produces the wines and fruits commonly found in the upper regions of Italy; but in the northern parts, comprising Galicia, part of Hungary, Bohemia, and Moravia, with the whole of Austrian Silesia, the cold is often severe.

The soil of Austria is also various, including almost every species from the most barren to the most fertile. Sandy plains are frequently found, in which nothing can grow; whilst the banks of the Po and Danube are, in point of luxuriance, scarcely to be equalled. Of the land of Austria not less than 24,000,000 joch, each about an English acre and a half, is occupied by forests. These are in general of the finest timber and of the greatest importance to the empire. That of Belevar in Hungary, situated on the Drave, consists for the most part of different species of oak trees, thousands of which, at a considerable distance above the root, are seven feet in diameter, and continue nearly the same size to the height of thirty, forty, and even fifty feet, without throwing out a single branch. But though Austria is wholly, from its situation, an agricultural empire, that science is imperfectly understood; and the late improvements are scarcely known. Even endeavours for the more extensive promotion of agriculture have been unsuccessful, owing to the want of a better mode of tenure and a better understanding between the cultivators and the proprietors. The productions of some parts of the empire are nevertheless numerous and excellent, embracing all that can administer to the necessities and even luxuries of life. Austria Proper yields corn, wine, and fruits. Bohemia pulse, grain, hops, &c. Hungary produces millet, maize, and rice. The valleys of Carniola produce oil and excellent wine, with fruits, millet, and flax; while the sub-alpine regions yield all the productions of southern climes, abounding in oranges, lemons, vines, peaches, figs, and tobacco. From a recent calculation by M. Blumenbach, it appears that the present quantity of arable land in Austria is about 43,582,000 acres; of which, allowing one-third for fallow, there remains 29,054,700 productive acres; and of grain alone the annual produce has been calculated at 360,000,000 Winchester bushels, or about 12·4 for every acre. The land in Austria devoted to the cultivation of wine is about 2,324,660 acres, and the produce about 493,109,565 gallons, being about 212 gallons per acre; besides which, the vineyards of Smymriam alone yield 70,000 cimers of spirit, distilled from the grapes, after the wine has been drawn from them, each cimer equal to fifteen English gallons; and the same spirit is produced in the other provinces in equal proportion. The whole value of the vegetable production of his imperial majesty's dominions has been estimated at the annual sum of £68,500,000 sterling, and the waste lands have been calculated at 25,271 English square miles.

The domestic animals are chiefly horses, cattle, buffaloes, sheep, swine, &c. Efforts have been made to improve the breed of horses, by the introduction of the Arabian and other species amongst them, which have been commonly suc-

cessful. The emperor established a breeding-stud at Mezöhegyes in Hungary, about the year 1783. It occupies four commons, containing 63,000 English acres, employs 500 men, and furnishes the army alone with 1000 horses annually. Attention has likewise been paid to the improvement of sheep, and of the wool imported to England, as Saxon, a great part is the produce of the Hungarian flocks. The cattle are mostly of a bluish slate-color; they feed chiefly in the forests, where they are protected from the heat of the sun, and are a considerable source of wealth to the inhabitants. The chief wild animals of Austria are those common on the European continent, consisting chiefly of wolves, boars, lynxes, &c. The chamois and the marmot are common.

Of the feathered tribes may be enumerated bustards and pelicans, and some species of the falcon. A few birds are also found upon the mountains of Carniola, which are peculiar.

The mineral riches of Austria are considerable, and are more varied and important than those of most other states in Europe. Near Kremnitz, in Hungary, are mines of gold and silver. Silver mines are also found in Chemnitz, about twenty miles south of the latter. Schmelnitz and Herengund contain valuable mines of copper. Antimony, coal, salt, and alum are also found in different parts of the empire. The opal is a mineral peculiar to Hungary, and as a gem is held in high estimation throughout the east. It is found in the mines of Kzerweriza, east of Kremnitz, in all states and qualities, from the semi-opal to the finest and most valuable. Gold ore is obtained of several kinds. The gray gold ore is found in the Najiag, north-east of Deva, and is peculiarly rich. The white gold ore is found a few leagues north of Karlsburg. To the west of the same town are mines of the same metal, in the vicinity of Zalantha. To the north of the province are those of Kapnich, and in the southern parts fresh gold mines are also said to have been recently discovered. Bohemia contains ancient mines of gold, silver, copper, and lead, in which are found perhaps the finest garnets in the world. Styria produces the finest steel; and mercury is said to be found in many parts of the empire. The Austrian mines altogether employ more than 35,000 persons, and the annual produce has been calculated at 2100 marks of gold, 93,000 of silver, 62,000 centvers of copper, 44,000 of iron, and 23,000 of lead. Excellent marble, and also mineral springs, are common in many parts of Austria.

Vienna, the capital, and centre of its commerce, lies near the site of the ancient Vindobona, towards the eastern confines of Germany, on a plain where the Vien falls into the Danube. The whole city approaches to the figure of a cone, of which the apex is formed by St. Stephen's church, and the circumference by the basis of the external lines of the fortification. The church of St. Stephen is the chief ornament of the city: it has a beautiful spire covered with fretwork, and a roof distinguished by the finest Mosaic tiling. This edifice is closely connected with the history of Austria; and their chief princes, heroes, and sages, sleep within its walls. The church of the

Augustines, and the imperial palaces, attract considerable attention.

Prague is the second city in Austria, and the capital of Bohemia, containing 80,000 inhabitants. It derives its name from a bridge which crosses the Mulda, 1800 feet long and thirty-five broad; on the battlements of which are thirty-two statues of saints, and at each end a high gothic tower of exquisite architecture. Its buildings and gardens are fine and numerous, although the former are many of them in ruins. Its university, which was founded by Charles IV. in 1347, was long considered as the great depository of German literature, and attended by 40,000 students, but now can scarcely boast the attendance of 400 ragged boys. The other chief towns of Austria are Presburgh, the capital of Hungary; Lemberg, the capital of Galicia or Austrian Poland; Gratz, the capital of Styria; Venice, the capital of the Venetian territories; Olmutz, the ancient capital of Moravia; Milan, the capital of the late kingdom of Italy; Mantua, the capital of the Mantuan territories; Trent, Brescia, Pavia, Padua, Verona, Trieste, Lintz, Saltzburgh, Troppau, Clausenburgh, Carlstadt, Hermannstadt, Toeplitz, and Edenburg, Schemnitz, and Kremnitz, in the mining districts; Brunn, the modern capital of Moravia and Debretzin; Pesh, the Transacincum of the Romans; and Buda, sometimes called Offen-Buda, the last two contiguous to each other, and only separated by the Danube. They are often regarded as one city, and considered by many geographers as the capital of Hungary. There are several other considerable towns, though of inferior importance.

The chief manufactures of Austria are cotton, thread, linen, lace, silks, stuffs, stockings, spirituous liquors, brass, iron, and steel; agricultural and kitchen utensils, glass, porcelain, and earthenware. The manufacture of some of these is confined to particular districts; cotton is manufactured chiefly in Austria Proper, where the British machinery and improvements have been introduced, and no fewer than 360,000 persons are constantly employed. Linen is manufactured chiefly in Bohemia and Moravia, although some of the finest qualities are obtained from Austrian Silesia, where upwards of 80,000 pieces are produced annually. The iron forges of Austria are about 1000, and are chiefly in Bohemia, in the country near the Enns, and in Styria. The last of these contains 200 of them, and produces 17,000 tons of wrought iron and steel annually. The steel ware of Carlsbadt is in high repute in many parts of Europe. Glass and porcelain manufactures are carried to a considerable extent in several parts of the empire; of the former there are no fewer than 170 works; nearly one half of which are in Bohemia, where magnificent services and beautiful highly finished lustres are made. Plate glass is carried to great perfection at Neuhaus. Leather, gunpowder, tobacco, sugar, and cinnamon, receive considerable attention in several districts; and the jewellers of Vienna are much renowned for polishing precious stones.

From a jealousy of foreign manufactures there is no great fair held in the Austrian states, except at

Botzen, on the Italian frontier; but several markets have been instituted for the interchange of domestic commodities. The rivers of Austria in some parts, greatly facilitate and improve the inland trade, whilst the great commercial roads afford the means of supplying even the secluded inhabitants of the Alps with all the comforts and conveniences of life. The chief imports of Austria consist of the raw materials, as wool, cotton, raw silk, drugs, oil, rice, and spices, received chiefly from the Levant. They export their own manufactures. Austrian consuls have been placed about the Levant and other parts of the Mediterranean, under the protection of Trieste and Constantinople, for the advantage of commerce; and the Greek merchants, who trade with them, are obliged, as a security to the state, to have a certain proportion of visible property in the empire.

The established religion of Austria is the catholic, but since the time of Joseph II. full toleration has been granted to all religious professions; and in Hungary, Transylvania, and Slavonia, members of the Protestant and Greek churches are numerous, and are settled in the enjoyment of considerable privileges. The ecclesiastical establishment has nine archbishops, viz. those of Vienna, Gran, Kolocza, Prague, Lemberg, or Leopold, Olmutz, Layback, Udina, and Milan. Under these there are above thirty Catholic bishops, and six of the united Greek church. The archbishop of the pure Greek church has his seat at Carlowitz, in the eastern part of Slavonia, and has nine suffragans under him. The archbishop of Gran is the metropolitan of Hungary, and by virtue of his office is lord lieutenant, primate, and chancellor of the kingdom. He has power to create nobility within his own archi-episcopal dominions, and possesses an annual revenue of £36,000 sterling. The emperor is considered as the head of the church, and in Hungary is considered as pope. He appoints bishops, regulates their incomes, establishes or suppresses monasteries at his pleasure, and frequently applies their revenues to other purposes.

In point of literature Austria is, at present, greatly behind the other provinces of Germany, owing to the unpolished state of the languages; their want of connexion with the more refined and classical tongues of Europe, together with the restrictions of government. The influence of bigotry, too, has often blasted the bud of genius, and neutralized every effort to promote its development and perfection. There are, however, a few names of eminence in various departments of knowledge; and the arts and sciences are now said to be upon the advance in Austria, but in the fine arts, it would be difficult to find an eminent sculptor or a good painter. Architecture is so little cultivated, that their best public buildings are generally planned by foreigners. In the mechanical arts they have evinced considerable native genius; but like that of the Germans, generally, its efforts have seldom been directed to any useful purpose. One mechanic has constructed a machine that performs all the functions of an expert chess player; another has made a head capable of imitating all the varied sounds of the

human voice; and a third has invented an instrument that emits, simultaneously, all the sounds of music. In the latter science they have been thought to excel, and the names of Hadyn and Mozart, whose powers and taste were formed at Vienna, have sufficiently established their national fame. In mathematics, astronomy, and botany, they have also succeeded to a certain extent; and amongst the numerous professors of these sciences, Burke, and the Abbe Treisnecker, have eminently distinguished themselves. But education, and consequently general knowledge, in Austria has been much neglected. The empress Maria Theresa, who patronised learning, established schools in every part of the empire; which, with others that have since been added, have in a measure relieved the intellectual gloom which for so long a period shrouded the south of Germany. Universities, lyceums, district academies, gymnasiums, Latin schools, schools for teaching their native tongue, schools for diffusing the elements of religion, are now universal; and are supported at the expense of government. The young men are compelled to attend the line of study marked out for them, under pain of forfeiting all civil offices and employments.

In Vienna, alone, are sixty schools for instructing the poor in reading, writing, and arithmetic; one normal school, preparatory to the gymnasium; three gymnasia, in which the studies prescribed by government are, mathematics, geography, history, natural history, arithmetic, composition, classics, and religion; the Theresian academy, for the sons of the Catholic nobility and foreigners of distinction, under the care of a director, twenty-one professors, ten masters of modern languages, and several additional tutors; and an university, provided with forty-five professors, extra teachers, &c. The school of surgery at Vienna, is considerable; there are also imperial medical academies, imperial military academies, imperial poly-clinic schools, for teaching the scientific principles of all trades and manufactures, and an imperial academy of oriental languages. Their universities, besides Vienna, are Prague, Pesh, Erlau, Lemberg, Milan, Mantua, Padua, and Pavia. To many of these public institutions are attached extensive libraries. That connected with the university of Vienna contains 90,000 volumes, and the Imperial Library upwards of 200,000. The doors of the latter are regularly open several hours in the day for the use of the citizens, who are permitted to read any of the volumes in apartments provided for that purpose.

The languages of Austria are several, of which the Gothic or German is most prevalent. The Slavonic is common in part of Hungary, Galicia, Bohemia, and Moravia. The proper Hungarian is a dialect of the Scythian. Latin is also spoken in Hungary; and on the borders of Turkey the Wallachian language, which is a corruption of the Latin, is prevalent. The Italian is the common language of the southern provinces, and French is spoken by the higher classes.

The Austrians are, generally speaking, handsome and athletic, of German origin, mixed insensibly with the native inhabitants of Italy, Hungary, and Bohemia. The grand German

outline is still visible, accompanied with the darker complexion, bolder features, blacker eyes, and more animated expression, which distinguish the countenance of the Austrian from those of his northern neighbours. They are a sensual people, but sensuality never enervates them. They possess an instinctive indifference to what would excite all the passions of an Englishman, and would rush from the ball to the battle, from the comic theatre to the field of blood, with apparent indifference; owing not to phlegmatic coldness, but to a peculiar felicity of temperament, which nature has conferred upon the constitution of the Austrian, by which he possesses an astonishing power of forbearance and self-command. The persons, manners, and accomplishments of the Austrian females have considerably attracted the attention of modern travellers, and have called forth some very lively and pertinent remarks from the pen of Mr. Lemaistre. 'The Austrian ladies,' says he, 'are the handsomest women I have seen on the continent; their countenances are expressive, and their complexions uncommonly fair. In beauty they are exceeded by no females in Europe; excepting only our own country-women, whose unrivalled superiority I believe is universally acknowledged. In manner they are elegant, and in conversation lively and well informed. Much greater attention seems to have been paid to their education, than is usual in other parts of the continent: all of them speak French with as much fluency as German, and some are proficient in English. The best works in these languages are familiar to them. They are completely free from pedantry; and I have had frequent reason to admire the taste and knowledge displayed in their remarks.' But as Austria is composed of separate kingdoms and states, whose manners and habits are many of them peculiar, we defer further particular observations on this till we come to treat of those states separately.

If we except Bohemia, Moravia, the northern parts of Austria, and a part of Hungary, this kingdom formed an integral part of the Roman empire, and abounds in antiquities and curiosities both natural and artificial. Castles, churches, and monasteries are common everywhere, whilst the southern parts, being near the centre of Roman power, are proportionably rich in ancient remains. The amphitheatre of Pola, about forty miles south of Trieste, stands near the extremity of a small peninsula, on the eastern shore of the Adriatic. This ancient edifice is elliptical in its figure, having three floors and rustic arcades, like the outer wall of the amphitheatre at Verona. Its length is 416 feet, and height ninety-seven feet. This is the only one of the ancient Roman elliptical precincts that now remains entire, those of Rome and Verona being much broken and dilapidated. Some imagine it to have been a theatre, and not an amphitheatre, because the seats only occupy one side, and are formed on the declivity of a hill. The amphitheatre at Verona is another building of the same description, though not so large, as the Coliseum at Rome; only a small part of the wall is standing, and the rest of the building scarcely rises above the summits of the surrounding houses. The seats

within, constructed of stone, were renewed in the sixteenth century, and now form the surface of a large hollow inverted cone, capable of accommodating upwards of 22,000 persons. A part of these seats are enclosed in a small wooden theatre, in which plays are performed during the summer. The structure exhibits a fine specimen of Roman architecture, composed of squared masses of marble from Sant. Ambrosio, about nine miles distant. The soffit stones of the arcades are nine feet long. Some parts of the building are composed of large flat bricks, which have withstood the action of the sun and weather for 1700 years, and yet remain uninjured by time. The precinct of this ancient amphitheatre is 522 feet long, embellished by three tiers of rusticated arcades, ninety-six feet high, and before the falling of the fourth story of rectangular windows, presented a grand and pleasing appearance. The disposition of the seats, and of the stairs leading to them, is better seen in this amphitheatre than in any other Roman antiquities of the same kind; and the remains generally are in a better state of preservation. See AMPHITHEATRE.

The natural curiosities of Austria are numerous and interesting. The various Alpine scenery, glaciers, chasms, caves, curious depositions of stones, &c. have in all ages commanded the admiration of the traveller, and the attention of the antiquarian. Austria Proper contains a singular assemblage of rocks, near Trautenau in Bohemia, in the shape of flowers, reaching from fifty to 100 feet in perpendicular altitude, and of great extent; supposed to be the remains of a mountain, the intermediate parts of which have been removed. Near Szadello, about thirty miles north-west of Kaschau in Hungary, is a celebrated cavern, which runs under the mountains to the distance of several miles, and has never been completely explored. It includes a multiplicity of distinct caves and winding passages, separated by numerous impending stalactites; the whole forming so intricate a labyrinth, that Dr. Townson, who visited this country a few years ago, says, 'a man once lost in it, though he had lights and food to last him a month, would not be able to find his way out.' A party of curious travellers, it is said, once remained in it for three days without being able to explore its dimensions, or reach the opening. Near Szalitze, in the Carpathian range, is another remarkable cavern, within which is a small glacier; and at Demanovo is a curious cave, which contains the bones of numerous wild animals. Various other subterranean domes and caverns have also been found in all parts of the calcareous mountains, beneath the towering summits of the Alpine regions. The lake of Czirknitz, in the Illyrian provinces eastward of Trieste, is one of the most singular natural curiosities of the Austrian territories. It is about four English miles in length, and nearly that measure in breadth, surrounded with mountains on all sides, and of the depth of five or six feet. Although there is no visible place for the discharge of them, in June or July the waters subside, and at length are seen to retire into a number of caverns at the bottom of the lake; the herbage of the bed then begins to grow rapidly, and produces considerable crops,

which are cut and preserved; after which the ground is grazed by cattle. In November, when the rains fall upon the adjacent hills, the waters issue again from their caverns, swell by reason of still gathering accessions, and spread into a perfect lake as before. The lake of Jessero, in the isle of Cherso, is classed among the natural curiosities of Austria, and said to discharge its waters but once in four or five years. In the same island are several curious caverns, in which have been found numerous fossil bones of oxen, horses, sheep, and other animals; amongst which none have been recognised as human. The salt-mines of Wieliczka, on the confines of Poland, exceed description; and those near Salzburg, on the western border of Austria, present an appearance so magnificent and sublime, as to be rated among the most stupendous and astonishing phenomena of Europe.

The islands belonging to Austria are few and unimportant, lying along the north-east shore of the Adriatic, from the Gulf of Juarnero to the southern point of Dalmatia. The principal are, Veglia, Osero, Grossa, Cherso, Lesina, Melida, and Brazza.

Of the provinces which make up the grand imperial dominions of Austria, many of them have constitutions different from each other. Hungary, as an hereditary and limited monarchy, has been in the house of Austria ever since the year 1437, when the archduke, having married the only daughter of king Sigismund, succeeded to the crown. The nation, however, shares the legislative and executive power with the emperor, who exercises his authority only through the medium of the States, a kind of parliament assembling at fixed periods for the transaction of public business. The Hungarian nobility also possess great power; and they alone, in state language, are included under the appellation of the Hungarian people, the rest being regarded as an inferior race of beings. Bohemia, Moravia, and the Tyrolese, also have an influence in the general government, and possess, to a certain degree, the privileges of Hungary. But in most of the provincial diets, the authority of the crown is so great, that the representatives can determine little else than the mode of raising taxes, so that the emperor is in a considerable degree unlimited in his sovereignty. In the ancient diet of the empire, Austria, independent of her electoral vote for Bohemia, had seven votes in the college of princes for the seven states of Austria Proper, Carinthia, Styria, Brixen, Trent, Tyrol, and Carniola. In the new diet, or 'confederation of the sovereigns and free towns of Germany,' formed in 1815, Austria, without having any superiority over the other states in point of rank, was declared by the Congress of Vienna (act fifty-seventh), to have the presidency with a vote. In the general assembly Austria has now four votes. The executive government consists of four great departments, established at Vienna, organized originally by the counsels of Maria Theresa. One of these regulates the internal concerns of the empire, another its foreign affairs, a third its military conduct, and the fourth the government of Hungary. These different parts of the administration are identified in numerous

boards, chanceries, councils, ministries, &c. The laws and jurisprudence of his imperial and royal apostolic Majesty's dominions, are in the general very vague and complicated. Bohemia and Moravia are divided into circles, each under a separate court of judicature from which lies a right of appeal to the supreme tribunal in the provincial capital. Every county in Hungary has its ruling assembly and court of justice, subject to an appeal to the district judicature, thence to the royal tribunal at Buda, and thence to the king in person. A new code of mild and salutary laws has however been recently drawn up at the instance of the government, and promulgated; the criminal part, in 1804, and the civil in 1812; which are made the universal code of jurisprudence for the the Austrian empire.

The entire revenue of Austria has been calculated at twenty-two millions, arising chiefly from taxes on the land, and articles of internal consumption. Joseph II. proposed a new land and poll tax, which has since been lucrative. The imperial domains, monopoly of tobacco, duties on stamps, hair-powder, glass, china, starch, wine, beer, brandy, carriages, legacy duties, fees on titles of nobility, toleration tax on the Jews; together with the duties arising from the crown lands, mines, coining, salt, tolls, fines, penalties, passing the frontiers, incomes upon vacant bishoprics, salaries, pensions, &c. of Hungary, constitute a considerable part of the above sum. Paper money has been frequently employed by Austria in her distress; and bank notes to the amount of £100,000,000 were in circulation as recently as 1810. The national debt, before the French revolution, amounted to £20,000,000, in 1805, it had increased to £30,000,000, and is at present £150,000,000. Of this two-thirds was created by the issue of paper money, which, however, is not deemed re-payable at its nominal amount.

The military establishment of Austria under Joseph II. rose into considerable importance; and in 1784, though a season of peace, the Austrians were able to muster more than 200,000 men; and after the French revolution, at the peace of 1797, they kept in pay an army of nearly 300,000. There were lately in the Austrian army no fewer than nine field-marsals, twenty-one generals of artillery, thirteen generals of cavalry 136 lieutenant-generals, 258 major-generals. Since 1805, however, the troops of Austria were greatly reduced, till she reached her ebb in 1809, having lost about one-eighth part of her population, and one-tenth of her resources. Afterwards her army amounted to 470,000 men; and in the campaign of 1813 and 1814, when she took the field afresh against the common enemy, her troops were more numerous than at any former period. Austria at present, as one of the united kingdoms, supplies 94,822 men to the military establishments of the German Confederacy, which is one in every hundred of her population in Germany, and, allowing the same proportion for all the other parts of the empire, the standing army of Austria will amount to 280,000 men. The Bohemian army is, however, stated at 50,000 men, which is about one in every sixty-four of the population. The Hungarian army is calcu-

lated at twelve regiments of infantry, and ten of hussars, the former consisting each of 3837 men, and the latter of 1698, forming an aggregate of 63,000; which, compared with seven millions and a half, the present population of Hungary, yields about the proportion of one to every hundred and twenty. The Hungarian army consists of three separate classes of individuals—the nobles, who are called together at the pleasure of the sovereign; the standing army, kept up by recruiting and conscription; and those of the military frontiers, where every man holds his possessions on condition of being ready to take up arms when called upon. Austria has nothing that deserves the name of a maritime force, but provides a few frigates and armed vessels for the protection of trade. The vessels called *tschaiken*, manned with about 1000 seamen and soldiers, are placed on the Danube towards the Turkish frontiers at the expense of government. There are in the Austrian states the following orders, having the emperor or empress at their head: the Golden Fleece, Maria Theresa, St. Stephen, Elizabeth, and the Star and Cross.

Of the political and historical memoirs of Austria, the reader will be able to form but a very imperfect idea. To write the history of a kingdom composed of kingdoms, with separate histories of their own; kingdoms too, which have been connected with other kingdoms, and those kingdoms, which have made a figure upon the earth, have balanced for ages the crisis of European power and politics, have given rise to governments, laws, manners, and language, and to surrounding nations, whose histories have also been embarked upon the stream of time, and intermingled with the politics of other states, is a work of no small difficulty. The Austrian history, if not obscure, is at least perplexed. The revolutions, alike incident to all human governments, the fluctuations of empire, the ebb and flow of territory, have been so frequent and considerable, that the high and low water mark of boundary at different periods of history, during the spring and neap tides of national influence and power, are only to be sought successfully in larger geographical treatises, and would require a distinct detail of relation beyond what the limits of an encyclopædia can possibly allow.

The original population of Austria was principally Gothic and Slavonic, and the descendants of the former still constitute the principal part of the inhabitants. Moravia and Bohemia were stocked by the latter, whilst the southern territories were inhabited by the descendants of the cisalpine Gauls, and the Roman colonies, which had been planted there. Only a small part of the present imperial dominions belonged originally to the house of Austria. The vicissitudes to which it has been subject from the period of its origination, are what have chiefly contributed to raise the empire to its present rank among European sovereignties, and to trace those vicissitudes down the variable narrative of their political story, affords an interesting topic in geographical speculation.

The princes of these houses are descended from the ancient dukes of Alsace, and bore the title of counts of Hapsburg, from the castle of

that name in the Aar on Switzerland, their patrimonial residence, before their accession to the imperial throne of Germany. In 1273 count Rodolph was elected king of the Romans, and bestowed the duchy on his son Albert, with whom, therefore, the house of Austria commences. This duchy was formed of the ancient margraviate, with that part of Bavaria situated above the river Enns; and passed to the house of Hapsburg as a fief of the empire, on the extinction of the old ducal family. The counts of Hapsburg at that time possessed a great part of Oberland in Switzerland, and a considerable portion of Suabia, to which, in 1284, were added Styria, Carinthia, and Carniola. But Albert, who was elected king of the Romans in 1298, during the revolutionary troubles of Switzerland, which happened about nine years after his accession, lost all his hereditary possessions in that country. The acquisition of Tyrol in 1364 made some addition, and Albert II. the next duke of Austria, was invested, in 1438, with the imperial purple, which has, ever since that period, been retained by his descendants in almost uninterrupted succession. The emperor Maximilian, grandfather to Charles V. acquired the territory of the low countries by marriage, and in like manner his son Philip, espousing the heiress of the Spanish crown, obtained the possession of that kingdom, with the dominion of the American colonies. At his decease the united kingdoms of Austria, Spain, and Spanish America, descended to his successor Charles V. who, about the year 1527, added those of Hungary, Bohemia, Moravia, Silesia, and Lusatia, when Austria appeared in the zenith of her glory. In 1556 Charles V. made over the Spanish dominions, and the Netherlands, to his son Philip II. under whom they suffered considerable diminution; the seven united provinces of the Netherlands entirely throwing off their allegiance. In 1648, at the conclusion of the thirty years war, Austria was obliged to relinquish the two provinces of Lusatia and Alsace, ceding the former to the elector of Saxony, and the latter to the king of France; but shortly after the emperor Leopold, son of Ferdinand III. added the whole of Transylvania, and considerably enlarged the boundaries of Hungary, after which few fluctuations occurred in the empire till the reign of Charles VI. when the peace of Utrecht in 1713, and the Barrier Treaty, two years afterwards, added Belgium, the duchy of Milan, the kingdom of Naples, and the island of Sardinia, which last was six years afterwards exchanged with the duke of Savoy, for the isle of Sicily. By the peace of Passarowitz, in 1718, Charles VI. acquired the Bannat of Temeswar, Belgrade, part of Servia, Bosnia, and Walachia; all of which, however, except the Bannat, were restored to the Porte in 1739. In 1735, after an unsuccessful opposition to France, the kingdom of Naples, and the island of Sicily, were made over by the Emperor to the infant Don Carlos of Spain, in exchange for the duchies of Parma and Placentia. At last, after various changes, as well in the outline as in the inward policy of the empire, Charles VI. died, in 1740,

and with him ended the male succession of the Hapsburg house of Austria.

Maria Theresa, eldest daughter and heiress of the deceased emperor, was married, in 1736, to Francis duke of Lorraine, afterwards grand duke of Tuscany; and immediately on her advance to the sovereignty had to carry on a long and extensive war against Prussia, Saxony, Bavaria, and Spain; all of whom made pretensions to some part or parts of her dominions. After a powerful but unsuccessful struggle for empire, Prussia, in the year 1742, obtained the greater part of Silesia, and the country of Glatz; and Spain, about six years afterwards, took possession of the duchies of Parma, Placentia, and Guastalla. The war of 1756 producing no remarkable change of territories, the Austrian boundaries continued the same, with little variation, till the partial dismemberment of Poland, in 1773, when she acquired Galicia and Ladomaria; and was still further augmented, in 1777, by the addition of the Bukowine; and in 1778, by the accession of the Innviertel on the side of Bavaria.

The first emperor of the Lorraine branch was Joseph II. who, after sharing the government with his mother Maria Theresa for several years anterior to her decease, was fully vested with the sovereignty in 1780. His reforms in the executive branches of government, abolition of sinecures, suppression of convents, modification of the dependence of the clergy upon Rome, and the perfect toleration of all dissenters, though they have been censured as the extreme of imprudence, were decidedly promoted for the consolidation of his immense territories, the manumission of his subjects from the civil disabilities under which many of them labored, and the establishment of a more worthy system of regular administration. To whatever extent such measures might have been neutralized by an obvious precipitancy, and rashness in the mode of execution, they show a great monarch, influenced by the best of principles, laboring in the common cause of humanity, justice, and patriotism; directing all his efforts towards the happiness of his people, and the welfare of his dominions. It is said that a visit which he received from pope Pius VI. two years after his accession, effected no alteration in his designs. After an active but variable reign, rendered remarkable towards the close, by a new war with the Turks, he died on the 20th of February, in the year 1790, and was succeeded by his brother Leopold II. who died at the commencement of the revolutionary war, on the 1st of March, 1792. The crown of Austria then descended to his eldest son, Francis II. the present emperor, and the sovereignty of the grand duchy of Tuscany to his second son Ferdinand. From this time the empire of Austria began to decline.

At this period the population of the empire was estimated at 25,000,000, and was increased, in 1796, by the accession of a great part of Poland, which was then finally dismembered and divided between Austria, Russia, and Prussia: but it was reduced to little more than its former amount the following year by ceding to France, Lombardy, the

Netherlands, and all the Austrian districts on the left bank of the Rhine. The war of 1799 gave early hopes of success, but the withdrawal of Russia from the coalition, and the fatal days of Marengo and Hohenlinden, obliged Austria to conclude a treaty with France in 1801; in which, although she obtained Salzburg and Berchtolsgaden, she was deprived of nearly all her Venetian states. The third war, in 1805, proved still shorter and more disastrous; and after the overthrow at Ulm and Austerlitz, the remainder of the Venetian states, Tyrol and Suabian principalities, containing a population of 3,000,000, were given as the price of peace; a period was likewise put to the Germanic constitution, and the title of Emperor of Austria substituted for Emperor of Germany and King of the Romans. In 1809 the resistance of Spain to Buonaparte prompted Austria to enter upon a new war with France. Her army was numerous and well disciplined, and a large portion of the French was employed in the peninsula; but the decided neutrality of Prussia, and the circumstance of Russia and Bavaria, with the states composing the confederation of the Rhine, taking part against Austria, enabled Buonaparte to acquire a decided victory, and once more to enter Vienna. This led to further losses, but

left the emperor no alternative but a treaty; the terms were the union of the emperor's daughter with Napoleon in marriage, and the sacrifice of considerable territory and population; namely, the provinces of Carniola, Trieste, Villach, the greater part of Croatia, and Agram, West Galicia, the circle of Zamosc, a circle in East Galicia, the greater half of Hansrueckviertel, the Innviertel, Berchtolsgaden, and Salzburg, the whole including 45,000 square miles and nearly three millions and a half of inhabitants. Austria remained overawed by France until the destruction of the French armies in Russia, when she again asserted her independence; and the subsequent success of the allies reinstated her in more than her former splendor. The ninety-third act of the Congress of Vienna restored nearly all that had been lost, while the succeeding one annexed several others on the side of Italy, which more than compensated for the remaining deficiency. The dominions of the Austrian empire, as fixed by this congress, have, according to Blumenbach, been divided into twenty-one provinces, or governments, besides the four dependent states. To these he assigns the following extent and population.

I.—AUSTRIAN EMPIRE.				Ger. sq. miles.	Inhabitants.
1.	The kingdom of Bohemia			956·80	3,203,222
2.	The margraviate of Moravia			417·64	1,680,935
3.	The dukedom of Silesia			86·85	
4.	Austria below the Enns			363·65	1,048,324
		Ger. sq. miles.	Inhabitants.		
5.	{ Austria above the Enns	151·86	417,625	344·32	756,897
	{ Circle of the Inn and Hansrueck	59·92	197,537		
	{ Saltzburgh	132·54	141,699		
6.	The duchy of Styria			398·98	799,056
7.	The duchy of Carinthia			190·90	278,500
8.	{ Illyria	190·61	358,831	250·95	467,836
	{ Part of Croatia	60·34	108,205		
9.	The coast district			176·18	422,861
10.	Tyrol and Vorarlberg			520·44	717,542
11.	The Lombardo-Venetian kingdom			867·50	4,111,535
12.	The government of Dalmatia			274·94	295,089
13.	The kingdom of Galicia			1526·12	3,755,454
14.	Civil Hungary, Croatia and Slavonia			4097·06	8,200,000
15.	Civil Transylvania			1118·70	1,510,000
16.	Transylvanian military frontiers				
17.	Bannat frontiers			186·00	171,675
18.	Sclavonian frontiers			139·40	230,079
19.	Warasdiner military government			67·40	107,217
20.	Carlstädter military government			166·40	188,906
21.	Bannat regiments			54·20	95,442
				12,204·43	28,040,570
II.—DEPENDENT STATES.					
1.	Grand dukedom of Tuscany			431·00	1,170,000
2.	Dukedom of Modena			92·31	375,000
3.	Dukedom of Massa and Carrara, with Garfagnana			23·00	60,000
4.	Dukedom of Parma			101·62	383,000
				647·93	1,988,000

AUSTRIA, SAN FELIPE DE, a city of South America, in the province and government of Cumana, forty-eight miles from Cumana, and containing 70 families. Long. 62° 11' W., lat.

10° 31' N. There is another small place of the same name, four leagues south-west of Cumana.

AUSTRIACUS, in ornithology, a species of falco, named by Latham the Austrian kite. *Gmelin.*

AUSTRO AFRICUS, the S. S. W. wind.

AUSTROMANCY, AUSTROMANTIA, properly denotes soothsaying, or a vain method of predicting futurity, from observations of the winds.

AUSTURCUS, or OSTURCUS, in ornithology, a goshawk; from whence we usually call a falconer, who keeps that kind of hawks, an ostringer. In ancient deeds, there has been reserved, as a rent to the lord, unum austurcum.

AUSURIANI, in Roman antiquity, a military order, similar to that of hussars among the moderns.

AUTENIGUA, the name given by the natives to a region of southern Africa, on the east of the Cape of Good Hope; and signifying, in their language, the land of honey. It now forms part of the district of Zwelenddam, and is represented by Vaillant as a delightful region, having a great variety of surface and scenery, great fertility, and abundance of honey. It was partially inhabited by Dutch colonists, whilst in possession of that nation; but it has been much improved since it came under the authority of the English. It abounds with all the wild animals common to southern Africa. See ZWELLENDAM.

AUTENOW, a town of Russia, in the government of Kiow, eighteen miles W. S. W. of Bialacerkier.

AUTER DROIT, in law, is where persons sue, or are sued, in another's right; as executors, administrators, &c.

AUTER VIE; in law, a person who holds an estate by the life of another is usually called tenant per auter vie.

<p>AUTHENTICATE, AUTHENTICAL, AUTHENTICALY, AUTHENTICNESS, AUTHENTICITY, AUTHENTICK, AUTHENTICKLY, AUTHENTICKNESS</p>	}	<p>Gr. αυθεντικως, Lat. cum auctoritate, with authority. Certo auctore, the author being well known; to make known the author, to give up the author, or authority; to refer to; to rely on information; to vouch for the truth of a statement. Authentic seems to have been the proper epithet for a physician regularly bred or licensed. The diploma of a licentiate runs, 'Authentice licentiatius.'</p>
---	---	--

Thirdly, it appeareth by registers and records indicially and *authentiquely* made, yet preserved for confirmation of the same. *Hall. Henry VIII.*

This point is dubious, and not yet *authentically* decided. *Brown's Vulgar Errors.*

Of statutes made before time of memory, we have no *authentic* records, but only transcripts. *Hale.*

Thou art wont his great *authentick* will
Interpreter through highest heaven to bring. *Milton.*

She joy'd th' *authentick* news to hear,
Of what she guess'd before with jealous fear. *Cowley.*

Conscience never commands or forbids any thing *authentically*, but there is some law of God which commands or forbids it first. *South.*

But censure's to be understood
The *authentic* mark of the elect,
The public stamp heav'n sets on all that's great and good. *Swift.*

Nothing can be more pleasant than to see *virtuosos* about a cabinet of medals, descanting upon the value, rarity, and *authenticness* of the several pieces.

Addison.

The nations that, according to the best *authenticated* history, appear to have been first civilized, were those that dwelt around the coast of the Mediterranean sea.

Smith's Wealth of Nations.

AUTHENTICS, AUTHENTICÆ, in the civil law, is a name given to the Novels of Justinian. The reason of the denomination is not well known. Alciat will have it to have been first given them by Accursius. These novels were originally composed in Greek, and afterwards translated into Latin by the patrician Julian, who reduced them into less compass. And in the time of Bulgaris, there was a second version made, more exact and literal, though not quite so elegant as the former. This translation being preferred by Accursius, he called it *authentica*, by way of preference to that of Julian, as being more conformable to the original. They are hereby distinguished from some other publications of later imperial constitutions, which are not regarded as of much authority.

AUTHIE, a river of France, which rises in the department of the Straits of Calais, and falls into the sea between the Somme and the Canche.

AUTHON (John d'), a French historian of the sixteenth century, abbot of Angle in Poitou. He wrote the history of France from 1490 to 1508, which has never been all printed. He died in 1523.

<p>AUTHOR, v. & n. AUTHORESS, AUTHORITATIVE, AUTHORITATIVELY, AUTHORITY, AUTHORIZATION, AUTHORIZE, AUTHORLESS, AUTHORSHIP.</p>	}	<p>Some contend for the Latin <i>auctor</i>, from <i>augeo</i>, <i>auctum</i>, to increase, i. e. to carry on an undertaking. It seems to relate more to the ground than to the form of the work. Others refer its origin to <i>αυθεντικως</i>, or the root which it represents. Whether this etymology be admitted or not, the verb and its correlatives convey the ideas of beginning, creation, foundation, invention, countenance, support, and power.</p>
--	---	--

They consider the main consent of all the churches in the whole world, witnessing the sacred *authority* of Scripture, ever sithence the first publication thereof, even till this present day and hour. *Hooker.*

ISAB. O but man, proud man,

Drest in a little brief *authority*,
Most ignorant of what he's most assured,
His glassy essence like an angry ape,
Plays such fantastick tricks before high heav'n,
As makes the angels weep.

Shakspeare. Measure for Measure.

Idle old man,

That still would manage those *authorities*
That he hath giv'n away! *Id. King Lear.*
That which is the strength of their amity, shall
prove the immediate *author* of their variance.

Shakspeare.

I know, my lord,

If law, *authority*, and pow'r deny not,

It will go hard with poor Antonio. *Id.*

But I suffer not a woman to teach, nor to usurp *authority* over the man, but to be in silence.

Paul.

War mends but few, but spoils multitudes; it legitimates rapine, and *authorizes* murder.

Jeremy Taylor,

Although their intention be sincere, yet doth it notoriously strengthen vulgar error, and authorize opinions injurious unto truth. *Brown's Vulgar Errors.*

Now while the tortur'd savage turns around,
And flings about his foam, impatient of the wound;
The wound's great author close at hand provokes
His rage. *Dryden's Fables.*

Yourself first made that title which I claim,
First bid me love, and authoriz'd my flame.

Dryden.

The obligation of laws arises not from their matter, but from their admission and reception, and authorization in this kingdom. *Hale.*

Power arising from strength, is always in those that are governed, who are many: but authority arising from opinion, is in those that govern, who are few. *Temple.*

The woods are fitter to give rules than cities, where those that call themselves civil and rational, go out of their way, by the authority of example. *Locke.*

The faith or persuasion of a Divine revelation is a Divine faith, not only with respect to the object of it, but likewise in respect to the author of it, which is the Divine spirit. *Tillotson.*

From his loins

New authors of dissension spring; from him

Two branches, that in hosting long contend

For sov'reign sway.

Philips.

A more decisive proof cannot be given of the full conviction of the British nation, that the principles of the Revolution did not authorize them to elect Kings at pleasure, than their continuing to adopt a plan of hereditary protestant succession in the old line. *Burke.*

AUTOCARDMIL, in antiquity, an order of musicians, who wore an ivy crown or garland. Scaliger seems to rank them in the number of mimi.

AUTOCEPHALUS; from *αυτος*, ipse, and *κεφαλη*, head: a person who has no one over him. This denomination was given, by the Greeks, to certain archbishops who were exempted from the jurisdiction of patriarchs. There were several other bishops in the east, who were autocephali; and in the west those of Ravenna pretend to the same right.

AUTOCHTHONES, an appellation assumed by some nations, implying that they sprung, or were produced, from the same soil which they still inhabited. In this sense autochthones amounts to the same with aborigines. The Athenians value themselves on their being autochthones, either, or *γηννητοι*, earth-born: see *ATTICA*, at being the prevailing opinion among the ancients that, in the beginning, the earth, by some prolific power, produced men, as it still does plants.

AUTOCRAT, { Gr. *αυτος*, himself, and
AUTOCRASY, { *κρατος*, power; the pos-
AUTOCRATICAL, { sessor of uncontrollable
AUTOCRATIC, { power. 'The emperor of
Russia styled the autocrat of all the Russias.'

The Father will as authority in its own reason: but the Son, as power, and the Agent of all its acts. Reason is the external impulse or inclination of objects, and determines itself by an absolute authority. *S. Ath's Sermons, x.*

The Father, Son, and Holy Ghost, in respect of the same divinity, have the same autocratical power, dominion, and authority.

Pearson on the Creed.

AUTOCRATOR; from *αυτος*, himself, and *κρατος*, power; a person vested with an absolute independent power, by which he is rendered unaccountable to any other for his actions. The power of the Athenian generals, or commanders, was usually limited; so that at the expiration of their office, they were liable to render an account of their administration. But, on extraordinary occasions, they were exempted from this restraint, and sent with uncontrollable authority: in which case they were styled *Αυτοκρατορες*. The same people also applied the name to some of their ambassadors, who were vested with a full power of determining matters according to their own discretion. These were denominated *Πρεσβεις Αυτοκρατορες*, and resembled our plenipotentiaries.

AUTO DA FE, or act of faith. See *ACT*.

AUTODIDACTUS; from *αυτος* and *διδασκο*, to learn; a person self-taught, or who has had no master or assistant of his studies.

AUTOGENIAL; from *αυτος* and *γεννομαι*, to beget, self-begotten.

AUTOGYPHUS LAPIS, a stone mentioned by Plutarch, as having naturally impressed on it the figure of Cybele. It is said to have been found in Sagaris a river of Persia. Doubtless if any such stone ever existed, the priests had it made to deceive the people.

AUTOGRAPH, *αυτος*, myself, and *γραφο*, I write. An original manuscript.

He did accurately describe and turn into Latin from the original *autographe* in Cambridge public library. *Wood's Athenæ Oxoniensis.*

AUTOLITHOTOMUS, one who cuts himself for the stone. Of this we have a very extraordinary instance given by Reiselius, in the *Ephemerides of the Academy Natura Curiosorum*, dec. 1, an. 3, obs. 192.

AUTOLOGIST; from *αυτος*, self, and *λογος*, speech; one who speaks much of himself.

AUTOLOGY, speaking of or to one's self.

AUTOLOLE, an ancient people of Mauritania, descended from the Gætuli. They excelled all their neighbours in running.

AUTOLYCUS, in fabulous history, a son of Mercury by Chione, a daughter of Dædalion. He was one of the Argonauts, famous for his cunning as a thief. After stealing the flocks of his neighbours, he altered their marks, and mingled them with his own. But Sisyphus, son of Æolus, discovered his craft; and when Autolycus stole his flocks, he picked out his own by a mark which he had made under their feet. The artifice of Sisyphus pleased Autolycus so much, that he directly formed an intimacy with him, and even allowed him freely to enjoy the company of his daughter Anticlea, who became pregnant of Ulysses, and was soon after espoused to Laertes.

AUTOLYCUS, a Greek mathematician and astronomer of Pitane, in Æolia, who flourished about 320 years before Christ. He was preceptor in mathematics to Arcesilaus, who was also a disciple of Theophrastus, the successor of Aristotle. His works extant are, a Treatise on the Movable Sphere, published by Dasypodius in Greek and Latin, 8vo. at Strasburg, in 1758; and in a Latin translation in the Synopsis Ma-

thematica of Mersennus, published in 4to. at Paris, in 1644; and also a Treatise on the Rising and Setting of the Stars, edited, with the former work, by Dasypodius. Diog. Laert. Vit. Arcesil. Fabr. Bid. Græc. tom. ii. p. 89. Montucla, Hist. Mathem. t. i. p. 192.

AUTOMATE, called also HIERA, one of the Cyclades, an island on the north of Crete, said to have emerged out of the sea, between the islands Thera and Therana, in the fifth year of the emperor Claudius; in extent thirty stadia.

AUTOMATON, } Gr. *Αυτοματός*. Ex. μα-
 ΑΥΤΟΜΑΤΟΥΣ, } *την*, frustra, vel *μαομαί*, ex-
 ΑΥΤΟΜΑΤΙC. } citor. Something self-
 moved; deriving its motion from internal ma-
 chinery.

Clocks, or *automatous* organs, whereby we distinguish of time, have no mention in ancient writers.
Brown's Vulgar Errors.

For it is greater to understand the art whereby the Almighty governs the motions of the great *automaton*, than to have learned the intrigues of policy.

Glanville's Scepais.

The particular circumstances for which the *automata* of this kind are most eminent, may be reduced to four.
Wilkins.

AUTOMATON may be farther defined, a machine, so constructed by means of weights, levers, springs, wheels, &c. as to move for a considerable time, as if endued with animal life. According to this definition, clocks, watches, and all machines of that kind may be ranked as a species of automata. But the word is most commonly applied to such machines as are made in the form of men and other animals, at the same time that their internal machinery is so contrived, that they seem voluntarily to act like the animals they represent. It has fallen in the way of the writer of this paper to have been making a few collections on this subject for some years past; and, observing that the whole direction of mechanical genius to these inventions has at present terminated in amusing, rather than any particularly useful machines, he has often entertained himself with considering the powers of man as a mere animal machine, in contrast with their inventions; the highest and best of which imitate his motions.

Political economists have frequently amused themselves and the public with the nicely-balanced powers of man as a propagating and eating animal, and philosophers and divines often assure us that he is, in other and higher respects, but a machine of a superior description; in especial deference to the latter grave authorities, we, therefore, take it for granted in this paper, that man is a machine, and shall not presume to arrogate for him any higher pretensions. We know nothing of his impulses as an animal, nor of the duties or influences to which he is subject as a rational being, if such he be; we only propose to introduce to our readers a variety of claimants for the honor of having made a part of him—of imitating portions of his organs, in their actual exercise—and isolated actions of his very mind. What wonder, if, in the progress of these efforts, our artists should

occasionally have struck off a complete and clever duck, a learned fly, or a royal eagle!

Automata have been favorite objects of mechanical contrivance from a very early period. If the term, indeed, may be allowed to include what some writers have considered under it, their history would quickly swell into a volume. The celebrated Glanville, for instance, speaks of 'the art whereby the Almighty governs the motions of the great automaton' of the universe! Bishop Wilkins ranks the sphere of Archimedes amongst the *αυτοματα σταρα*, 'or such as move only according to the contrivance of their several parts, and not according to their whole frame.' It was, in fact, an early orrery, according to Claudian:

Jupiter in parvo cum cerneret æthera vitro,
 Risit, et ad superos talia dicta dedit;
 Hucine mortalis progressa potentia cure?
 Jam meus in fragili luditur orbe labor, &c.

This learned prelate has even extended the application of the term to machines moved, by external forces or elements, as mills, ships, &c. Its modern acceptation, however, and that to which we shall restrict ourselves, will not include all machines that are self, or internally moved. It is confined to the mechanical imitations of the functions and actions of living animals, and particularly those of man.

The celebrated story of the statue of Memnon, one of the wonders of Ancient Egypt, has some pretensions to lead the way in this historical sketch. We have positive testimony (Strabo, lib. xvii.) to the circumstance of the most beautiful sounds being emitted from this statue, at the rising and setting of the sun; and from the pedestal, after the statue was overthrown. What was the contrivance in this case, it may be vain to conjecture; but automata are, by profession, a puzzling race. If a certain disposition of strings, exposed to the rarefaction of the air, or to the morning and evening breezes, after the manner of our Æolian harps, produced these sounds; or if any method of arranging the internal apertures so as to receive them from a short distance, were the artifice, a considerable acquaintance with the science of music, and with acoustics generally, will be argued. Wilkins quotes a musical invention of Cornelius Drebel, of similar pretensions, which 'being set in the sunshine, would, of itself, render a soft and pleasant harmony, but being removed into the shade would presently become silent.'

The statues and the flight of Dædalus are equally famous, and, perhaps, fabulous. Aristotle, however, speaks of the former in his treatise *De Anima*, lib. i. c. 3. as successful imitations of the human figure and human functions in walking, running, &c. and attempts to account for their motions by the concealment of quicksilver.

Archytas's flying dove, originally mentioned in Favorinus, is another of the ancient automata. The inventor is said to have flourished about B. C. 400, and was a Pythagorean philosopher at Tarentum. It was made of wood, and the principal circumstance of its history, which Fæ-

vorinus mentions, that is like some other birds of too much wing, when it alighted on the ground, it could not raise itself up again. Aulus Gellius, in his *Noctes Atticæ*, attempts to account for its flight, by observing, 'Ita erat scilicet libramentis suspensum, et aura spiritus inclusa atque occultâ consistum,' &c. that it was 'suspended by balancing, and moved by a secretly enclosed aura or spirit.'

Friar Bacon, we all know, made a brazen head that could speak, and that seems to have assisted, in no small degree, in proclaiming him a magician. Albertus Magnus is also said to have devoted thirty years of his life to the construction of an automaton, which the celebrated Thomas Aquinas broke purposely to pieces. Men, treated as these were by the age in which they lived, had no encouragement to hope that any details of their labors would reach posterity.

Amongst the curiosities of his day, Walchius mentions an iron spider of great ingenuity. In size it did not exceed the ordinary inhabitants of our houses, and could creep or climb with any of them, wanting none of their powers, except, of which nothing is said, the formation of its web. Various writers of credit, particularly Kircher, Porta, and bishop Wilkins, relate that the celebrated Regiomontanus (John Muller) of Nuremberg, ventured a loftier flight of art. He is said to have constructed a self-moved wooden eagle, which descended toward the emperor Maximilian, as he approached the gates of Nuremberg. It met him, and hovered over his person as he entered the town. This philosopher, according to the same authorities, also produced an iron fly, which would start from his hand at table, and after flying round to each of the guests, returned, as if wearied, to the protection of his master.

An hydraulic clock, presented to the emperor Charlemagne, by the caliph Haroun al Raschid, merits record in the history of these inventions. It excited the admiration of all Europe at the period of its arrival. Twelve small doors divided the dial into the twelve hours, and opened successively as each hour arrived, when a ball fell from the aperture on a brazen bell and struck the time, the door remaining open. At the conclusion of every twelve hours, twelve mounted knights, handsomely caparisoned, came out simultaneously from the dial, rode round the plate, and closed the doors. Dr. Clarke, in his last volume of *Travels* (part iii. Scandinavia, sec. 1. 4to. 1819), mentions a similar contrivance in a clock at Lubeck, of the high antiquity of 1405. Over the face is an image of Jesus Christ, on either side of which are folding-doors, which fly open every day as the clock strikes twelve. A set of figures, representing the twelve apostles, then march forth on the left hand, and, bowing to our Saviour's image as they pass in succession, enter the door on the right. On the termination of the procession the doors close. This clock is also remarkably complete, for the age, in its astronomical apparatus; representing the place of the sun and moon in the zodiac, the moon's age, &c. Similar appendages to clocks and time-pieces became too common, at the beginning of the last century, to

deserve particular notice. We should not, however, omit some of the productions of the Le Droz family, of Neufchatel. About the middle of last century, the elder Le Droz presented a clock to the king of Spain, with a sheep and dog attached to it. The bleating of the former was admirably correct, as an imitation; and the dog was placed in custody of a basket of loose fruit. If any one removed the fruit, he would growl, snarl, gnash his teeth, and endeavour to bite, until it was restored.

The son of this artist was the original inventor of the musical boxes, which have of late been imported into this country. Mr. Collinson, a correspondent of Dr. Hutton's, thus clearly describes this fascinating toy in a letter to the doctor, inserted in his *Mathematical and Philosophical Dictionary*:—'When at Geneva, I called upon Droz, son of the original Droz, of La Chaux de Fond, where I also went. He showed me an oval gold snuff-box, about, if I recollect right, four inches and a-half long, by three inches broad, and about an inch and a-half thick. It was double, having an horizontal partition; so that it may be considered as one box placed on another, with a lid, of course, to each box. One contained snuff; in the other, as soon as the lid was opened, there rose up a very small bird, of green enamelled gold, sitting upon a gold stand. Immediately this minute curiosity wagged its tail, shook its wings, opened its bill of white enamelled gold, and poured forth, minute as it was (being only three-quarters of an inch from the beak to the extremity of the tail) such a clear and melodious song as would have filled a room of twenty or thirty feet square with its harmony.'

In Ozanam's *Mathematical Recreations*, we have an account, by the inventor, M. Camus, of an elegant amusement of Louis XIV. when a boy. It represented a lady proceeding to court, in a small chariot drawn by two horses, and attended by her coachman, footman, and page. When the machine was placed at the end of a table of proper size, the coachman smacked his whip, the horses started off with all the natural motions, and the whole equipage drove on to the farther extremity of the table; it would now turn at right angles in a regular way, and proceed to that part of the table opposite to which the prince sat, when the carriage stopped, the page alighted to open the door, and the lady came out with a petition, which she presented with a courtesy to the bowing young monarch. The return was equally in order. After appearing to await the pleasure of the prince for a short time, the lady courtesied again, and re-entered the chariot, the page mounted behind, the coachman flourished his whip, and the footman, after running a few steps, resumed his place.

About the same period, M. Vaucanson, a member of the Academy Royal of France, led the way to the unquestionable superiority of modern times, in these contrivances, by the construction of his automaton duck, a production, it is said, so exactly resembling the living animal, that not a bone of the body, and hardly a feather of the wings, seems to have escaped his imitation and direction. The radius, the cubitus, and the humerus had each their exact offices. The auto-

maton ate, drank, and quacked in perfect harmony with nature. It gobbled food brought before it, with avidity, drank, and even muddled the water after the manner of the living bird, and appeared to evacuate its food ultimately in a digested state. Ingenious contemporaries of the inventor, who solved all the rest of his contrivances, could never wholly comprehend the mechanism of this duck. A chemical solution of the food was contrived to imitate the effect of digestion.

This gentleman is also celebrated for having exhibited at Paris, in 1738, an androïdes (from *ανθρωπος*, a man, and *ειδος*, a form; a term under which some scientific works have classed all the automata that have been made to imitate the human person), a flute-player, whose powers exceeded all his ancestry; and for the liberality and good sense with which he communicated to the academy, in the same year, an exact account of its construction. The figure was nearly six feet in height, and usually placed on a square pedestal four feet and a-half high, and about three feet and a-half broad. The air entered the body by three separate pipes, into which it was conveyed by nine pairs of bellows, which were expanded and contracted at pleasure, by means of an axis formed of metallic substances, and which was turned by the aid of clock-work. There was not even the slightest noise heard during the operations of the bellows: which might otherwise have discovered the process by which the air was conveyed ad libitum into the body of the machine. The three tubes, into which the air was sent by means of the bellows, passed again into three small reservoirs concealed in the body of the automaton. After having united in this place, and ascended towards the throat, they formed the cavity of the mouth, which terminated in two small lips, adapted to the performance of their respective functions. A small movable tongue was enclosed within this cavity, which admitted or intercepted the passage of the air into the flute, according to the tune that was executed, or the quantity of wind that was requisite for the performance. A particular species of steel cylinder, which was turned by means of clock-work, afforded the proper movements to the fingers, lips, and tongue. This cylinder was divided into fifteen equal parts, which caused the ascension of the other extremities, by the aid of pegs, which pressed upon the ends of fifteen different levers. The fingers of the automaton were directed in their movements by seven of these levers, which had wires and chains attached to their ascending extremities; these being fixed to the fingers, caused their ascension in due proportion to the declension of the other extremity, by the motion of the cylinder; and thus, on the contrary, the ascent, or descent, of one end of the lever, produced a similar ascent, or descent, in the fingers that corresponded to the others; by which one of the holes was opened or stopped agreeably to the direction of the music. The entrance of the wind was managed by three of the other levers, which were so organized as to be capable of opening or shutting, by means of the three reservoirs. By a similar mechanical process, the lips were under

the direction of four levers; one of which opened them in order to give the air a freer passage; the other contracted them; the third drew them back; and the fourth pushed them in a forward direction. The lips were placed on that part of the flute which receives the air; and, by the different motions which have been already enumerated, regulated the tune in the requisite manner for execution. The direction of the tongue furnished employment for the remaining lever, which it moved in order that it might be enabled to shut or open the mouth of the flute. The extremity of the axis of the cylinder was terminated on the right side by an endless screw, consisting of twelve threads, each of which was placed at the distance of a line and a half from the other. A piece of copper was fixed above this screw; and within it was a steel pivot, which was inserted between the threads of the screw, and obliged the cylinder above-mentioned, to pursue the threads. Thus, instead of moving in a direct turn, it was perpetually pushed to one side; the successive elevation of the levers displaying all the different movements of a professed musician.

M. Vaucanson constructed another celebrated androïdes, which played on the Provençal shepherd's pipe, and beat, at the same time, on an instrument called the tambour de basque. This was also a machine of the first order for ingenious and difficult contrivance. The shepherd bore the flageolet in his left hand, and in the right a stick, with which he beat the tabor, or tambourine, in accompaniment. He was capable of playing about twenty different airs, consisting of minuets, rigadoons, and country-dances. The pipe, or flageolet, which he was made to play, is a wind-instrument of great variety, rapidity, and power of execution, when the notes are well filled and properly articulated by the tongue; but it consists only of three holes; and the execution, therefore, mainly depends upon the manner in which they are covered, and the due variation of the force of the wind that reaches them. To give the androïdes power to sound the highest note, M. Vaucanson found it necessary to load the bellows, which supplied the air to this tone, with fifty-six pounds weight, while that of one ounce supplied the lowest tone. Nor was the same note always to be executed by exactly the same force of air; it was necessary to pay the most accurate attention to its place on the scale, and to so many difficult circumstances of combination and expression, that the inventor declares himself to have been frequently on the point of relinquishing his attempt in its progress. In the tambourine accompaniment, too, there were numerous obstacles to overcome; the variation of the strokes, and particularly the continued roll of this instrument, was found to require no small ingenuity of construction.

All other exhibitions of mechanical skill, in imitation of the powers of human nature, were destined, however, to give way, in 1769, to the pretensions of the chess-player of M. Wolfgang de Kempelin, a Hungarian gentleman, and aulic counsellor of the royal chamber of the domains of the emperor in Hungary. Called in that year

to Vienna, by the duties of his station, this gentleman was present at some experiments in magnetism, made before the empress Maria Theresa, when he ventured to hint that he could construct for her majesty a piece of mechanism far superior to any of those which had been exhibited. His manner of remarking this, excited the attention of the empress, who encouraged him to make the effort, the automaton chess-player, which has since been exhibited in all the capitals of Europe, was, within six months after this period, presented at the imperial court. It is a presumption in favor of the pretensions of this contrivance to be a master-piece of mere mechanism, that the original artist, after having gratified his exalted patroness and her court with the exhibition of it, appeared for many years indifferent to its fame. He engaged himself in other mechanical pursuits with equal ardor, and is said to have so far neglected this, as to have taken it partly to pieces, for the purpose of making other experiments. But the visit of the Russian grand duke Paul to the court of Joseph II. again called our automaton to life. It was repaired and put in order in a few weeks; and, from this period (1785), has been exhibited at intervals, through Germany, at Paris, and in London, first by M. de Kempelin, and latterly by a purchaser of the property from his son; De Kempelin having died in 1803.

Our chess-playing readers will be able to appreciate the bold pretensions of this automaton. The entire number of combinations which it is possible to form with the pieces of a chess-board has never, we believe, been ascertained. To push forward a plan of our own steadily, and at the same time to anticipate the designs of an antagonist, requires a constant and acute discrimination, which, long experience, and some considerable strength of memory, have been required to make availing in all other cases. But this cunning infidel (for he assumes the figure of a Turk) drives kings, and castles, and knights before him with more than mortal sagacity, and with his inferior hand: he never, we believe, has been beaten; and except in a very few instances of drawn games, has beat the most skilful chess-players in Europe. Dr. Hutton, on the supposition of its being altogether a mechanical contrivance, calls it 'the greatest master-piece of mechanics that ever appeared in the world.' We shall recount his pretensions in the words of an Oxford graduate, who published Observations on them, during his last visit in London, and subjoin a statement of the best attempts that have been made to account for his apparent skill.

The room where the automaton chess-player is at present exhibited, has an inner apartment, within which appears the figure of a Turk as large as life, dressed after the Turkish fashion, sitting behind a chest of three feet and a half in length, two feet in breadth, and two feet and a half in height, to which it is attached by the wooden seat on which it sits. The chest is placed upon four castors, and, together with the figure, may be easily moved to any part of the room. On the plain surface formed by the top of the chest, in the centre, is a raised immovable chess-board of handsome dimensions, upon which

the figure has its eyes fixed; its right arm and hand being extended on the chest, and its left arm somewhat raised, as if in the attitude of holding a Turkish pipe, which originally was placed in its hand. The exhibiter begins by wheeling the chest to the entrance of the apartment within which it stands, and in face of the spectators. He then opens certain doors contrived in the chest, two in front and two at the back; at the same time pulling out a long shallow drawer at the bottom of the chest, made to contain the chess-men, a cushion for the arm of the figure to rest upon, and some counters. Two lesser doors, and a green cloth screen, contrived in the body of the figure and its lower parts, are likewise opened, and the Turkish robe which covers them is raised; so that the construction, both of the figure and chest, internally, is displayed. In this state the automaton is moved round for the examination of the spectators: and, to banish all suspicion from the most sceptical mind, that any living subject is concealed within any part of it, the exhibiter introduces a lighted candle into the body of the chest and figure, by which the interior of the chest is, in a great measure, rendered transparent, and the most secret corner is shown. Here it may be observed, that the same precaution to remove suspicion is used, if requested, at the close, as at the commencement, of a game of chess with the automaton. The chest is divided, by a partition, into two unequal chambers. That to the right of the figure is the narrowest, and occupies scarcely one-third of the body of the chest. It is filled with little wheels, levers, cylinders, and other machinery used in clock-work. That to the left contains a few wheels, some small barrels with springs, and two quarters of a circle placed horizontally. The body and lower parts of the figure contain certain tubes, which seem to be conductors to the machinery. After a sufficient time, during which each spectator may satisfy his scruples and his curiosity, the exhibiter recloses the doors of the chest and figure, and the drawer at the bottom; makes some arrangements in the body of the figure, winds up the works with a key inserted into a small opening on the side of the chest, places a cushion under the left arm of the figure, which now rests upon it, and invites any individual present to play a game of chess. At the commencement of a game, the automaton moves its head as if taking a view of the board; the same motion occurs at the close of a game. In making a move, it slowly raises its left arm from the cushion placed under it, and directs it towards the square of the piece to be moved. Its hands and fingers open on touching the piece, which it takes up, and conveys to any proposed square. The arm then returns with a natural motion to the cushion upon which it usually rests. In taking a piece, the automaton makes the same motions of the arm and hand to lay hold of the piece, which it conveys from the board, and then returning to its own piece, it takes it up, and places it on the vacant square. *Observations, &c. by an Oxford Graduate*, 8vo, 1819. His motions have an air of great dignity and composure. On giving check to the king, he moves his head as a signal. When a false move is made, as if to puzzle him, he taps with his right hand on the chest, replaces the

piece wrongly moved, and proceeds to take the due advantage of moving a piece of his own. At other times he will tap on the chest for his adversary to move; and at the close of the game he bows gracefully round to the company. It is a remarkable, and somewhat suspicious circumstance, that neither the present proprietor of this automaton (in a pamphlet circulated by him on this subject), nor the Oxford graduate, from whose observations we have abridged the above account of his performances, takes any notice of the attempted solution of them by Mr. Collinson, a correspondent of Dr. Hutton, to whom we have before alluded. In the same letter in which this gentleman describes the automaton inventions of the Droz family, he speaks of a pamphlet presented to him at Dresden, which affirms the whole phenomena to be produced by human agency; a conjecture which is confirmed by a writer in the Edinburgh Encyclopædia. A well-taught boy is said to be partly concealed in the ample drapery of our automaton's lower limbs, and partly in the commode on which the chess-board is placed. He cannot be seen when the doors are opened, we are told, 'because his legs and thighs are then concealed in two hollow cylinders, which appear designed to support the wheels and levers, the rest of the body being at that moment out of the commode, and hid in the drapery of the automaton. When the doors of the commode are shut, the clacks which are heard by the turning of a rounce, permit the dwarf to change his place, and re-enter the commode without being heard; and while the machine is rolled about to different parts of the room, to prove that it is perfectly detached, the dwarf has an opportunity of shutting the trap through which he has passed. The drapery of the automaton is then lifted up, and the interior part of the body is shown, to convince the spectators that all is fair, and the whole terminates to their great astonishment, and in the illusion that an effect is produced by simple machinery, which can only arise from a well-ordered head.' This writer proceeds to conjecture, that the chess-board is semi-transparent, so as at once to conceal the party within, and afford him sufficient light to perceive the moves of his antagonist, which are met by an interior lever, governing the arm of the automaton, on the principles of the pantograph.

With these accounts of the chess-player very distinctly in his mind, and an extract of the supposed method of concealing the dwarf or boy, in his pocket, the writer of this paper went with some friends a short time ago, to visit, and, if possible, to play at chess with the automaton. His engagements, however, were far too numerous for the writer to obtain that honor on this occasion. Some slight changes had taken place in the manner of exhibiting the automaton (compared with the account of the Oxford graduate); having, therefore, avowed to the proprietor, that his object was to obtain a scientific knowledge of his proceedings, as far as it could be done with propriety, the writer took memoranda of what passed.

From a door in a canvass screen the automaton and commode were wheeled out at the

time appointed, and the figure was made to face the company. Then the inferior chamber of the commode (occupying about one-third of its dimensions), was opened before and behind, when a taper was held by the proprietor in such a situation, as to throw a full light through the machinery that occupied this part of it. He now closed and locked the doors of this chamber, opened the drawer, and took out the men and cushion; as described by the Oxford graduate; after which he opened the larger chamber of the commode in front, and put the taper through the front door within it. Perhaps one-sixth, or one-eighth of this chamber was occupied by machinery; the rest was a perfect cavity, lined with green baize. He now shut and locked these doors; then wheeled the commode round, opened and took up the drapery of the figure, and exhibited the body, partly occupied by machinery, and partly left with imperfect imitations of the prominent parts, to the shoulders. The drapery was then carefully pulled down, and the figure wheeled round, so as again to front the spectators, before whom it played a masterly and successful game. The conviction of the writer and his friends (with the figure before them) was, that the concealment of a small thin boy or dwarf was barely possible. The larger chamber would contain him, and that chamber never was opened from behind, nor at the same time that the back of the figure was exposed; while it is observable that the inferior chamber had the light of a taper thrown through it. So that it appeared a practicable contrivance that a boy should be concealed in the drapery while the commode was opened, and in the commode while the figure was exposed.

Under these impressions, the writer addressed a letter to the proprietor, in which he stated, that having with his friends, been highly gratified by the wonderful powers of the automaton chess-player, and intending to communicate the result of his investigation to the public, which must, if satisfactory, prove extremely creditable to the invention,—he requested leave to visit the exhibition (accompanied by two or three scientific friends, and probably in the presence of a member of the Royal family), in order to see a game played by the figure, with the doors of the commode open; his object being merely to ascertain the impossibility of any human intervention, and not in any degree to inspect the machinery; but to this application a polite negative was returned, declining any other than the ordinary public exposure of the machine.

Since writing the above, we have seen 'An Attempt to analyse the Automaton Chess-player of M. De Kempelin,' Lon. 1821. The anonymous author is sanguine enough to add, 'With an easy method of imitating the movements of that celebrated Figure.' The solution of these movements here offered to the public, is so far similar to our own, as that the writer confidently ascribes them to the concealed presence of a living agent. Five lithographic plates illustrates his supposed mode of operation. But this tract suggests, that the operator is introduced into the body of the automaton; that he sees the chess board, while playing 'through the waistcoat, as easily as through a

veel; and that his left hand actually fills the sleeve of the figure, moving the fingers 'with a string.' (Surely, to make this sort of agency complete, the chess-player might have been furnished with gloves!)

The author ingeniously finds a space at the back of the drawer, not heretofore noticed, which would receive the legs of a concealed person. He also makes some pertinent remarks on the illusion which is probably practised on the spectator in the winding up of the machinery, the ticking of clock-work that is heard, &c. We still imagine, however, that the dimensions of the chest would afford no room for the concealment of a figure that could thus direct the arm, and are certain no such figure could rise out of it into that part of the body supposed, as we saw it displayed in London. A youth coiled up in the commode would much more 'easily' play the game. The whole chest is but two feet and a half high, three feet long, and two feet in breadth. On the whole, we must leave the question of human agency still undecided, and pass on to the mention of another of M. de Kempelin's ingenious inventions.

'On what do you think M. de Kempelin is at present employed?' says M. de Wendisch, in a letter to a friend on the pursuits of that gentleman, in 1783—'on a machine that talks!' Acknowledge that he must be gifted with a creative genius bold and invincible, to undertake a project of this kind; and will it be believed that he has every reason to hope for complete success? He has already succeeded so far as to prove the possibility of such a machine, and to deserve on the part of the learned, that they should dedicate their attention to this new and hitherto unknown invention. His machine answers, clearly and distinctly enough, several questions. The voice is sweet and agreeable; there is but the letter R which it pronounces lispingly, and with a certain harshness. When its answer is not understood, it repeats it slower; and if required to speak a third time, it repeats it again, but in a tone of impatience and vexation. I have heard it pronounce in different languages, very well and very distinctly, the following words and phrases:—'Papa,' 'Mama,' 'My wife,' 'My husband,' 'A-propos,' 'Marianne,' 'Rome,' 'Madam,' 'The queen,' 'The king,' 'At Paris,' 'Come,' 'Mama loves me,' 'My wife is my friend.' This writer then speaks of the machine being at that time nothing more than a square box, to which was affixed a pair of organ-bellows; and that, at each answer of this non-descript speaker, the inventor put his hand under a curtain that covered it, to touch, apparently, the springs that produced the articulation. It appears to have been M. Kempelin's design to give to this automaton the form of a child of five or six years of age, as the voice which he produced was that of this period of life. He, however, exhibited it in an unfinished state; and we have not been able to learn to what figure it was finally adapted. The narrative of his proceedings in accomplishing what he did effect, and which we abridge from a curious treatise of his, 'On the Mechanism of Speech,' appears to us to be amongst the most interesting and useful of all the automa-

tical details. Our modern removers of impediments in speech may work wonders, perhaps, by looking into his artificial jaws!

The first object of M. Kempelin, though upon what ground he reasoned we cannot imagine, was the production of the vowel sounds, rather than those of any of the consonant, which he hardly expected to be able to combine with them. He investigated the affinity between the sound of various instruments and the human voice; and between the use of the artificial reed-stop, or *voce humana* (which has sometimes been applied to the natural organs), and the general functions of the glottis. To the honor of our northern countrymen, after exhausting his patience on qualifying and combining bassoon, with clarionet reeds, those of hautboys, &c. he found the reed of the Highland bagpipe to furnish the best practical basis of his attempts, and sounds approximating the nearest to the harmony divine of human speech! He now conceived that the fundamental powers of the voice were in A, the sound of which vowel he easily produced by combining the reed with a tube and a pair of organ-bellows; but beyond this he could not proceed, until it occurred to him that the organ of developing the sounds desired, demanded his principal attention. He divided, therefore, a deep elliptical box into two parts, which shut upon each other with a hinge, in the manner of the human jaws, connecting his tube with the back of it, and carefully varying their opening and manner of action, until he could command the sounds of O OU, and E. Year after year was devoted to this instrument, we are told; but I, or the German U, refused to obey his call. K, L, M, and P, however, rewarded his efforts; when he attempted to form the letters he had obtained, into syllabic combinations and words. Here an almost insuperable difficulty occurred; the sounds of the letters would not flow into each other without a clatter or pause. If too slowly enunciated, they would seem like a child repeating his alphabet, and have no resemblance to the word intended; and if the tube was too rapidly supplied, it would produce a catching gust of air in the mouth, which interrupted every letter with the sound of K. An aspirating sound following that of the consonants, was also very troublesome to overcome. In the beginning of the third year of his labor, he could execute, pretty accurately the words Papa, Mama, Aura, Lama, Mulo. The sounds of most of the other consonants were ultimately obtained. P, K, and T, required the greatest quantity of air, we are told; and the whole machine about six times the quantity of the human lungs. But the two latter consonants, with D and G, were always imperfectly articulated. Some of his best sentences were, *Romanorum Imperator semper Augustus. Leopoldus Secundus. Vous êtes mon ami. Je vous aime de tout mon cœur.* M. de Kempelin finally perfected, 1. Nostrils, which he found of great importance in articulation, and which consisted of two tin tubes, communicating at bottom with the mouth. 2. The mouth, made of elastic gum, and of a bell form, so contrived that the sounds of the reed issued immediately from it,

and connected with the air-chest by a tin tube, which kept it always full of air. 3. The air-chest, which was of an oblong shape, and received at one end the voice-pipe containing the reed, and at the other the bellows-pipe, both closed round with leather. In this chest were contained two inferior ones, each having a valve at the top closed by a spring, and a round aperture adapted to receive through the side of the larger chest a tin funnel, and a round wooden tube, which produced the hissing sounds of C H, J, S, and Z. The voice-pipe entered the larger chest between the two smaller ones. 4. The bellows, answering the purpose of lungs, and which acted in the ordinary manner of those belonging to an organ. 5. The reed, which was in imitation of a bagpipe drone, the hollow portion being square, and the tongue of it formed of thin ivory, vibrating horizontally, to produce the various sounds. The square end was inserted, as we have noticed, in the air-chest. Along the upper side of the tongue was a movable spring, which slightly bent it inward; and the part on which it fell was covered with leather, to modulate the vibrations. The sounds were more acute as the spring acted toward the outer extremity of the tongue, which was then more rapid in its motions; as it was withdrawn from this part, the vibrations were slower, and the sounds more grave.

The name of M. Maillardet, a Swiss artist, of modern celebrity, is the only one that merits association with that of De Kempelin. He has executed two or three celebrated figures. One of these is a lady at her piano-forte. She executes eighteen tunes by the actual pressure of her fingers on the keys; and while all the natural notes are thus performed, her feet play the flats and sharps by means of pedals. The instrument, in fact, may be correctly called an organ, as it is mainly moved by bellows; to bring which into proper action is the one important object of the machinery. The whole is impelled by six strong springs, acting on twenty-five communicating levers, and regulated and equalised by a brass fly. The interior of the instrument is, of course, very complicated and minute in its mechanism, which requires to be wound up once an hour. Before commencing a tune, the lady bows her head to the auditors; she is apparently agitated with an anxiety and diffidence, not always felt in real life; her eyes then seem intent on the notes, her bosom heaves, and at a distance it is impossible to discover any semblance of a work of art.

A magician, that has sometimes accompanied this musical lady, is also a considerable triumph of mechanical skill. He sits at the bottom of a wall, with a long wand in his right hand, and a book in his left. Questions inscribed on thin oval counters, twenty in number, are put into the spectator's hand, who is desired to enclose one or more of them in a drawer, which shuts with a spring. A medallion, for instance, has the question, What is the most universal passion? which being put into the drawer, the figure rises with a solemn gait, bows his head, draws a circle or two with his wand, consults his book, and lifts it towards his face, as if in meditation. He then strikes with his wand on the wall above

his hand, when two folding-doors open, and discover the inscription Love, as the reply. The counters are remarkably thin, and similar in all other respects but their inscriptions, which some of them bear on both sides: certainly the mechanism that can discriminate the one from the other, must be exquisite; and mechanism alone, we have the highest authority for believing it is.

M. Maillardet's Writing-boy is hardly less meritorious. He is exhibited kneeling on one knee, and an attendant having dipped his pencil and laid the paper before him, he executes drawings, and French and English sentences, in writing, of a very superior description. Every natural motion of the fingers, elbow, eyes, &c. is correctly imitated. The first of these figures the artist stated to have cost him the sum of £1500 in its construction.

The last machine of this kind which we shall notice is the engine invented by Mr. Babbage, capable of computing any table by the method or differences, whether they are positive or negative, or of both kinds. The greater the number of differences, the more will this engine outstrip the most rapid calculator; and by the application of certain parts of no great complexity, the roots of equations, and consequently the roots of numbers may be extracted.

One machine of this kind this gentleman has executed. Drawings and plans of a second have been made by him to multiply any number of figures by any other number; of a third, to make tables of prime numbers from 0 to ten millions; and of a fourth, to construct tables which have no order of differences constant. This last engine will calculate tables governed by laws which have not been hitherto shown to be explicitly determinable; and will solve equations, for which analytical methods of solution have not yet been contrived. Thus one of the greatest difficulties with which calculators are beset, arising from the errors of copyists, and of the press, is obviated. In Mr. Babbage's engine, the machine itself takes from several boxes, containing types, the numbers which it calculates: thus becoming at the same time computer and compositor; and preventing all error both in copying and in printing. It is worked by the hand, and it would be very easy, if any advantage were to be gained by such a method, to apply to it a self-moving power.

We have now placed before the reader as complete an account of the most celebrated automata as the limits of our publication will admit. We believe no remarkable contrivance of this kind has escaped our notice; and is it too much to ask him for one serious reflection, at the close, upon the wisdom of that Almighty Architect, by whom we are so fearfully, so wonderfully, so inimitably made? Without any speculation on the possible powers of man, or the tendency of his habits and impulses on a large and hypothetical scale, let the entire muscular action of a single youthful arm, in striking a shuttlecock, be perfectly imitated by him, and we could consent to resign to the artist the government of our share of the world!

AUTOMENES, one of the Heraclidæ, king of Corinth At his death, A. A. C. 779 annual ma-

gistrates were chosen at Corinth, who were called Prytanēs; and by them the Corinthians were governed for ninety years, till Cypselus and his son Periander assumed absolute power.

AUTOMEDON, in entomology, a species of papilio.

AUTOMOLI, a nation of Ethiopia, mentioned by Herodotus.

AUTOMOLITE, in mineralogy, a substance which, from its crystalline form, was considered to be a variety of spinelle, containing a portion of oxide of zinc. But a later and more accurate analysis has shown it to be an aluminate of zinc. It has hitherto been found only in Sweden, in small octahedral crystals, imbedded in talc.

AUTONINE (Bernard), a French lawyer, was advocate to the parliament of Bourdeaux. He was author of, 1. A Comparison of the French and Roman Law; 2. A Commentary on the Provincial Law of Bourdeaux; 3. Censura Gallicæ in Jus Civile Romanum.

AUTONOE, in fabulous history, a daughter of Cadmus, who married Aristeus, by whom she had Actæon, frequently called Autoneivis Heros. Actæon became a famous huntsman, but happening to look at Diana and her attendants bathing near Gargaphia, he was changed into a stag, and devoured by dogs; which was so afflictive to Autonoe, that she retired from Bœotia to Megara, and soon after died.

AUTONOMIA; from *αυτος*, and *νομος*, law; a power of being governed by our own laws and magistrates. The liberty of the cities which lived under the faith and protection of the Romans, consisted in their *autonomia*, i. e. they were allowed to make their own laws, and elect their own magistrates; by whom justice was to be administered, and not by Roman presidents or judges, as was done in other places, which were not indulged with the *autonomia*.

AUTOPHOROS; from *αυτος* and *φερω*, to bear, i. e. self-bearing; an epithet applied to a thief taken in the act with the stolen goods upon him.

AUTOPHOSPHORUS is, by some, used to denote phosphorus, on account of its kindling of itself.

AUTOPRACTI; from *αυτος*, and *πραττω*, I exact; in the civil law, persons indulged with this privilege, that they should not be compelled to pay taxes, but should be left to their own free will. Of this number were men of distinguished dignity, and those eminent for their probity and honor.

AUTOPSY. From *αυτος* and *ωψις*, a man's own sight, as distinct from that of others. Not in use.

In those that have forked tails, *autopsy* convinceth us, that it hath this use.

Ray on the Creation.

AUTOPYRITES, *Αυτοπυριτες*; from *αυτος*, and *πυρος*, wheat; in the ancient diet a species of bread, when in the whole substance of the wheat was retained, without retrenching any part of the bran. Galen describes it otherwise, viz. as bread where only the coarser bran was taken out. And thus it was a medium between the finest bread, called simlagneus, and the coarsest called furmaceus. This was also called the *symonistus*.

AUTOTHEISM, the doctrine of God's self-existence.

AUTOUR, in natural history, a sort of bark which resembles cinnamon, but is paler and thicker; it is the color of a broken nutmeg, and full of spangles. It comes from the Levant, and is an ingredient in the carmine dye. Also, in ornithology, the name under which Buffon describes the goshawk, or falco palumbarius of Linnæus.

AUTREAU (James d'), a French poet and painter, who died in great poverty, in the hospital of incurables in Paris, in 1745. His dramatic works were published in 4 vols. 12mo. 1749. He had little merit as a painter.

AUTRICUM, in ancient geography, 1. the capital of the Carnute, in Gallia Celtaica; afterwards called Carnotena, Carnotenas, and Civitas Carnotenum; now Chartres; and, 2. the ancient name of Auxerre.

AUTUMN, } Perhaps from *augeo*, *auc-*
AUTUM'NAL, } *tum*, from the augmented fruits
AUTUM'NITY, } of nature.

For I will board her though she chide as loud
As thunder, when the clouds in *autumn* crack.

Shakspeare.

Thy grandsire's words savour'd of thriftie leekes,
Or manly garlicke: but thy furnace reekes
Hote steams of wine; and can aloofe describe,
The drunken draughts of sweete *autummitie*.

Bp. Hall's Satires, book iii.

Thou shalt not long

Rule in the clouds; like an *autumnal* star,

Or lightning, thou shalt fall. *Milton.*

No spring or summer's beauty hath such grace,
As I have seen in one *autumnal* face. *Donne.*

Bind now up your *autumnal* flowers, to prevent
sudden gusts, which will prostrate all. *Evelyn.*

Not the fair fruit that on yon branches glows
With that ripe red th' *autumnal* sun bestows. *Pope.*

When men once reach their *autumn*, fickle joys
Fall off apace, as yellow leaves from trees;
Till left quite naked of their happiness,
In the chill blasts of winter they expire. *Young.*

Autumn, nodding o'er the yellow plain,

Comes jovial on. *Thomson.*

I would not be over-confident, till he hath passed
a spring or *autumn*. *Wiseman's Surgery.*

The starving brood,

Void of sufficient sustenance, will yield

A slender *autumn*. *Philips.*

The evening is an emblem of *autumn*, and *autumn*
of declining life. *Idler.*

AUTUMN begins when the sun enters Libra. When it *æcis*, winter begins. Several nations have computed their years by autumns; the Anglo-Saxons by winters. Tacitus tells us the Germans were acquainted with all the other seasons of the year, but had no notion of autumn. The ancient Jews began their civil year in autumn; reckoning that all the fruits of the earth were in perfection at the creation. The French, without regarding the principle, adopted the practice in their late revolutionary calendar; of which, the first month, Vendemiaire, commenced with the equinox. Thus faith and modern philosophy, in one instance, produced the same effect. Autumn has been reputed an unhealthy season. Tertullian calls it 'tentator valetudinum'; and the satirist speaks of it in the same light:

'Autumnus Libitinæ quæstus acerbæ'

Autumn is commonly represented by painters under the figure of a female crowned with vine branches, and bunches of grapes; naked in that part which respects summer, and clothed in that which corresponds to winter. Its garment is covered with flowers, like that of Bacchus.

AUTUMN, in alchemy, the season when the operation of the philosopher's stone is brought to perfection.

AUTUMNAL EQUINOX, the time when the sun enters the autumnal point.

AUTUMNAL POINT is that part of the equinox from which the sun begins to descend towards the south pole.

AUTUMNAL SIGNS, in astronomy, are the signs Libra, Scorpio, and Sagittarius, through which the sun passes during the autumn.

AUTUMNALIA, the fruits of the earth that ripen in autumn.

AUTUMNALIS, in ornithology, a species of psittacus, called also psittacus Americanus, and crick à tête bleue, by Buffon. It is the lesser green parrot of Edwards, and autumnal parrot of Latham. It is distinguished by being of a green color, with the front and spot on the quill-feathers scarlet; crown and primary quill-feathers, blue. Of this kind there are two varieties. Also a species of anas, or duck, that inhabits South America. And a species of fringilla, called by Latham the autumnal finch.

AUTUMNUS, in entomology, the name given by Ammiral to the moth, or phalæna, called by Gmelin P. FAGANA: which see.

AUTUN, an ancient city of France, in the department of the Saone and Loire, formerly the capital of the Autunois district, and now of an arrondissement, with nine cantons, and 67,000 inhabitants. Before the revolution the intendant of Burgundy resided here, and it was the see of a bishop, suffragan of Lyons. The Arroux washes its walls, whose ruins are so firm, and the stones so closely united, that they seem almost to be cut out of the solid rock. Among the antiquities of this city are the ruins of three ancient temples, one of which was dedicated to Janus, and another to Diana; two antique gates of considerable beauty, with a theatre and a pyramid; which last is probably a tomb. In the church of St. Martins is the tomb of the sanguinary Brune-hault, who is said to have poisoned her son Childebert, and to have procured the death of ten kings; and who met her death by being tied to the tail of a wild mare, by order of her grandson, Clovis II. The present bishop ranks under the metropolitan of Besançon, and exercises jurisdiction over the departments of the Saone and Loire, and the Nievre. Autun consists of the upper town, the castle, and the lower town. It is tolerably well built, contained before the revolution nine parish churches, five abbeys, with five other religious houses, and about 8000 inhabitants. The natives manufacture delft wares, carpets, coverlets, blankets, and tapestry. The city lies at the foot of three great mountains, sixteen leagues south-west of Dijon, and forty-five south-east of Paris.

AUTUNOIS, a ci-devant district of France, in Burgundy, now comprehended in the department of Saone and Loire. See AUTUN.

AUTURA, or AUDURA, a river of Gallia Celtica, now called Eure. It falls into the Seine, on the south side.

AUVAIL, a town of Germany, in the circle of Westphalia.

AUVERGNE, a ci-devant province of France, about 100 miles in length, and seventy-five in breadth; the capital of which was Clermont. It was bounded on the north by the Bourbonnois; on the east by Forez and Velay; on the west by Limosin, Quercy and La Marche; and on the south by Rovergue and the Cevennes: and was divided into upper and lower; the latter, otherwise called Limagne, being one of the finest countries in the world. The mountains of Upper Auvergne though not fruitful, afford good pasture, which feeds great numbers of cattle, the chief riches of that country. It now forms the two departments of Cantal and Puy-de-Dome, except some small districts annexed to those of Creuse Allier, and the Upper Loire. Auvergne is conspicuous in the various revolutions experienced by France, and anciently maintained a pre-eminence among the independent states of Gaul. Its inhabitants boasted a singular trophy in the sword of Cæsar, which he lost before the walls of Gergovia. But they maintained a faithful alliance with the Romans after they became subject to them.

AUVERGNIE, a town of Switzerland, in the canton of Neufchâtel, three miles south of that place.

AUVERS, a town of France, on the right bank of the Oise, in the department of the Seine and Oise, arrondissement of Pontoise. Also a town in the west of France, in the arrondissement of Le Mans, and department of the Sarthe.

AUVILLARS, or AUVILLARD, a town of France, in Lower Armagnac, Gascony, in the department of the Tarn and Garonne. It is the head of a canton, and contains manufactures of woollen stockings, and upwards of 2000 inhabitants. It stands on the Garonne, which here forms a small harbour. Five leagues south of Agen.

AUVERNAS, a very deep-colored heady wine, made of black raisins, so called at Orleans; but it is not fit to drink before it is above a year old; but if kept two or three years, it becomes excellent.

AUVIGNY (N. Castress'), a French historian of the eighteenth century. He was both a writer and a soldier, and lost his life at the battle of Dettingen, in 1743, at the age of thirty-one. His writings are, 1. Memoirs of Madam Barneveldt, 2 vols. 12mo. 2. Histories of Rome and France abridged for young persons. 3. History of Paris, 4 vols. 12mo. 4. Lives of illustrious Frenchmen, 8 vols. 12mo.

AVULSED, *Avello, avulsum*, I tear or AVULSION. \int pull away. Torn or pulled away.

Spare not the little offsprings, if they grow Redundant; but the thronging clusters thin

By kind avulsion.

Philips.

The pressure of any ambient fluid can be no intelligible cause of the cohesion of matter; though such a pressure may hinder the avulsion of two polished superficies one from another, in a line perpendicular to them.

Locke.

Ye towering minds! ye sublimated souls!
 Who scatter wealth, as though the radiant crop
 Glitter'd on every bough; and every bough,
 Like that the Trojan gather'd, once *avuls'd*
 Were by a splendid successor applied
 Instant, spontaneous! listen to my lays.

Shenstone's Economy.

AUX, in astronomy, see AUGES. Some use *aux* to denote the arch of the ecliptic, intercepted between the first point of Aries, and the point wherein the sun, or a planet, is at its greatest distance from the earth.

AUXENTIUS, bishop of Milan, in the fourth century. He was a native of Cappadocia, and of Arian principles. Constantius gave him the bishopric of Milan; and though excommunicated by a council held at Rome, in 368, he held his see to his death, in 374.

AUXENTIUS, another of the Arian party, who challenged St. Ambrose to a public disputation, which was wisely declined by that great prelate.

AUXERRE, an ancient town of France, the capital of the department of Yonne, formerly the capital of the Auxerrois, in Burgundy. The palace of the *ci-devant* bishop is one of the finest in France, and the churches are very beautiful. It is advantageously situated for trade with Paris, on a hill on the banks of the river Yonne, eleven leagues S. S. E. of Sens, and thirty-seven south-east of Paris. Its principal trade is in wood, and the excellent wares of the neighbourhood. Here is also a manufacture of woollen stuffs. Population about 12,000.

AUXERROIS, a *ci-devant* territory of France, in Burgundy, of which Auxerre was the capital. It now forms the greater part of the *arrondissement* of Auxerre, in the department of the Yonne.

AUXESIS, in mythology, a goddess worshipped by the inhabitants of Ægina, and mentioned by Herodotus and Pausanias.

AUXILIAR, } Lat. *auxilium*,
 AUXILIARY, *n.* & *adj.* } strength; one who
 AUXILIATORY. } gives or lends us additional strength. An aider, assister, or supporter.

The giant brood,

That fought at Thebes and Ilium on each side,
 Mix'd with *auxiliar* gods. *Milton's Paradise Lost.*
 Their tractates are little *auxiliary* unto ours, nor
 afford us any light to detenebrate this truth.

Brown's Vulgar Errors.

There is not the smallest capillary vein but it is present with, and *auxiliary* to it, according to its use.

Hale's Origin of Mankind.

Nor from his patrimonial heaven alone,
 Is Jove content to pour his vengeance down,
 Aid from his brother of the seas he craves
 *To help him with *auxiliary* waves. *Dryden. Ovid.*

They had both kept good company, rattled in chariots, glittered in play-houses, and danced at court, and were both expert in the games that were in their times called in as *auxiliaries* against the intrusion of thought.

Rambler.

AUXILIARY VERB. A verb that helps to conjugate other verbs. In almost all languages, some of the commonest nouns and verbs have many irregularities; such are the common auxiliary verbs, *to be*, and *to have*, *to do*, and *to be done*, &c.

AUXILIARY VERBS, in grammar, are prefixed to other verbs, to form their moods and tenses. In the English language, the auxiliary verb *am* supplies the want of passive verbs. All the modern languages make use of auxiliary verbs, because their verbs do not change their terminations as those of the Latin and Greek, to denote the different tenses or times of being, doing, or suffering; nor the different moods or manners of their signifying: so that, to supply this defect, recourse is had to different auxiliary verbs. See GRAMMAR.

AUXILIUM, in law. See AID.

AUXILIUM, AD FILIUM MILITEM FACIENDUM, vel filiam maritandam, was a writ directed to the sheriff of every county, where the king or other lord had any tenants, to levy them reasonable aid, towards the knighting of his eldest son, or the marriage of his eldest daughter.

AUXILIUM CURLE, signifies an order of court, for the summoning of one party at the suit of another.

AUXO, in mythology, the name of one of the two graces worshipped by the Athenians. See HEGEMONE.

AUXOIS, a small *ci-devant* territory of France, in Burgundy, of which Semur was the capital. It is now in the department of Cote d'Or.

AUXON, a town of France, in Champagne, department of the Aube, with 2340 inhabitants. 5½ leagues S. S. W. of Troyes. Also a town in Upper Auvergne, department of the Upper Loire, near the Allier, with 1500 inhabitants; and the title of barony. It carries on a traffic in corn, wine, and cloth. 12½ leagues north-west of Le Puy.

AUXONNE, the capital of a county of the same name in France, in the province of Burgundy, on the left bank of the Saone. It is regularly fortified, and contains manufactures of serge and other cloths.

AUXY, the French name of a species of wool, spun in the neighbourhood of Abbeville, by workmen, called *houpiers*. It is very fine and beautiful, and used to make the finest stockings.

AW, a river of Scotland, in Argyllshire. Also a town of Germany in the electorate of Bavaria

Aw, or LOCH-AW, a beautiful and extensive lake in Argyllshire, in the parish of Glenorchy. The whimsical tradition respecting the origin of this lake is recorded by Ossian. The substance of it is, that 'to Bera the aged, was committed the charge of that awful spring, which was appointed by fate to destroy the inheritance and race of her fathers. This event, she was to prevent, or at least to protract, by covering the spring before sun-set, with a stone, on which the sacred and mysterious characters were engraved. One night this was forgot. The confined waters of the mountain burst forth, and sweeping all before them, covered that large expanse, now known by the name of the Lake of Aw.' Mr. Stewart, minister of Stachur, explains the fable by the etymology of Bera; Beir, in the Gaelic signifying a thunderbolt. This lake is about thirty miles long, but not above three quarters broad upon an average, though in some places,

it measures two miles. It abounds with salmon, trout, eels, &c. The name is often spelt and generally pronounced Loch-ow.

AWA, a town of Persia, in the province of Irak, eighty miles south of Casbin.

AWA, a town of Japan, and capital of a province on the south coast of the island of Xicoco. Also a town of Japan, and capital of a province on the south coast of the island of Niphon, eighty-five miles south of Jeddo. Long. 140° 4' E., lat. 34° 24' N.—A town of Japan, in the island of Ximo, sixty-two miles north of Nangasaki.

AWAHAZARI, a town of Asiatic Turkey, in Caramania, fifteen miles N. N. W. of Alanieh.

AWAIT, *v. & n.* } Dutch, *waken*; Ang-
AWAIT'ER, *n.* } Sax. *Wæccean*, to wake or
AWAIT'ING. } watch. To be watchful,
vigilant; to keep upon the look out; to be in attendance, in expectation.

Even as the wretch condemn'd to lose his life,
Awaits the falling of the murdering knife. *Fairfax*

And least mishap the most bliss after may:
For thousand perils lie in close *await*,
About us daily, to work our decay. *Spenser.*

Advanc'd in view, they stand, a horrid front
Of dreadful length, and dazzling arms, in guise
Of warriors old with order'd spear and shield,
Awaiting what command their mighty chief
Had to impose. *Milton. Paradise Lost, book i.*

Nor less resolv'd, Antenor's valiant heir,
Confronts Achilles, and *awaits* the war. *Pope.*

Man's feeble race what ills *await!*
Labor and penury, the racks of pain,
Disease, and sorrow's weeping train,
And death, sad refuge from the storm of fate. *Collins.*

The boast of heraldry, the pomp of power,
And all that beauty, all that wealth e'er gave,
Await alike the inevitable hour,
The paths of glory, lead but to the grave. *Gray.*

AWAKE, *v. & adj.* } See AWAIT. To rouse
AWA'KEN, } from inaction of any
AWA'KENER, } kind; from sleep; to
AWA'KENING. } make alive.

K. RICH. I had forgot myself: am I not king?
Awake, thou coward majesty, thou sleepest;
Is not the king's name forty thousand names?
Shakespeare. King Richard II.

The cheerful lark, mounting from early bed,
With sweet salutes *awakes* the drowsy light,
The earth she left, and up to heaven is fled,
There chaunts her Maker's praises out of sight. *Fletcher.*

Covetous men need neither clock nor bell to *awaken*
them: their desires make them restless.

Hall's Contemplations.
'Tis night! the season when the happy take
Repose, and only wretches are *awake*;
Now discontented ghosts begin their rounds,
Haunt ruin'd buildings and unwholesome grounds. *Otway.*

And see!
'Tis come! the glorious morn! the second birth
Of heaven and earth! *awakening* nature hears
The new creating world, and starts to life,
In every heightened form, from pain and death
For ever free. *Thomson.*

See Truth, Love, and Mercy, in triumph descending,
And nature all glowing in Eden's first bloom!
On the cold cheek of Death smiles and roses are
blending,
And Beauty immortal *awakes* from the tomb. *Beattie's Hermit.*

AWAR'D, *v. & n.* } According to Tooke
AWAR'DER. } from the French *à garde-*
to keep; with a verb preceding, understood as
to determine who is [to keep;] to adjudge.
A pound of that same merchant's flesh is thine;
The court *awards* it, and the law doth give it. *Shakespeare.*

It advances that grand business, and according to
which their eternity hereafter will be *awarded*.
Decay of Piety.

A church which allows salvation to none without
it, and *awards* damnation to almost any within it. *South.*

Satisfaction for every affront cannot be *awarded* by
state laws. *Collier on Duelling.*

Now hear th' *award*, and happy may it prove
To her, and him who best deserves her love. *Dryden.*

Affection bribes the judgment, and we cannot expect
an equitable *award*, where the judge is made a
party. *Glanville.*

To urge the foe,
Prompted by blind revenge and wild despair,
Were to refuse th' *awards* of Providence. *Addison's Cato.*

Th' unwise *award* to lodge it in the tow'rs,
An off'ring sacred. *Pope. Odyssey.*

AWARD, in law, is the arbitrator's final ad-
judication, of matters referred to him. Refer-
ences are sometime made spontaneously
by the parties themselves, to avoid the ex-
pense and delay of legal proceedings; and
sometimes by order of the court before which a
cause is pending. In the former case, the par-
ties enter into bonds to abide by the decision;
in the latter an order or rule of the court is
made, that the matter in issue shall be deter-
mined by the award. Law as well as facts
are within the province of the arbitration. But
if in the award (which is in writing and under seal)
the arbitrator states the legal grounds on which
he has decided, and those grounds appear to the
court to be wrong, the award may be set aside.
If he merely makes his order without assign-
ing his reasons, the award must be abided by, though
he may have been mistaken in point of law. And
the courts will set aside an award, if the arbi-
trator can be shown to have made it from corrupt
motives.

AWARE, *v. & n.* } Sax. *waerd*. Germ.
AWAR'N. } *gewährht*, from *wahren*, to
see. To be on the look out, to be cautious, to
take care, to be provident.

So warn'd he them *aware* themselves; and
Instant, without disturb, they took alarm. *Paradise Lost.*

Ere I was *aware*, I had left myself nothing but the
name of a king. *Sidney.*

Ere sorrow was *aware*, they made his thoughts
bear away something else besides his own sorrow. *Id. Arcadia.*

Temptations of prosperity insinuate themselves; so
that we are but little *aware* of them, and less able
to withstand them. *Atterbury.*

The first steps in the breach of a man's integrity
are more important than men are *aware* of. *Steele.*

AWASI, or **AWADSI**, an island of Japan, near the south coast of Nippon, about sixty miles in circumference. Long. 133° 44' E., lat. 34° 30' N. Also, a town of Japan, and capital of an island of the same name. Long. 133° 43' E., lat. 34° 30' N.

AWASIMA, a small island of Japan, seven miles east of Sado.

AWATCHA, in ornithology, a species of motacilla that inhabits Kamtschatka. It is of a brown color; the chin and breast white, spotted with black; middle of the belly and lores white; primary quill-feathers bordered with white; tail-feathers orange at the base. Art. Zool.—Gmelin.

AWATSKA BAY, a harbour of Kamtschatka; which is said to be the safest and most extensive yet discovered in that part of the world; and the only one that can admit vessels of large burden. The entrance to it is in long. 158° 48' E., and lat. 52° 51' N.

AWAY', } Ang.-Sax. wagean, to wag
AWAYWARD. } or move; Ang.-Sax. weg, or
 waeg; Eng. way. Away is the imperative
 mood, or past participle.

A man's life is not to be trifled *away*: it is to be offered up and sacrificed to honourable services, public merits, good causes, and noble adventures.

Bacon's Essays.

I had my feather shot sheer *away*.

Beaumont & Fletcher, Knight of the burning Pestle.

They could make

Love to your dress, although your face were *away*.

Ben Jonson's Catiline.

It is impossible to know properties that are so annexed to it, that any of them being *away*, that essence is not there.

Locke.

So if by chance the eagle's noble offspring,
 Fa'en in the nest, become's some peasant's prize,
 Compell'd awhile to bear his cage and chains
 And like a prisoner with the clown remains
 But when his plumes shoot forth and pinions swell
 He quits the rustic and his homely cell;
 Breaks from his bonds, and in the face of day
 Full in the sun's bright beams he soars *away*:
 Delights thro' heav'n's wide pathless ways to go,
 Plays with Jove's shafts and grasps his dreadful bow.

Rowe's Royal Concert, act iv.

But ah! thou know's't not in what youthful play
 Our nights beguill'd with pleasure swam *away*;
 Gay songs and cheerful tales deceived the time,
 And circling coblets made a tuneful chime;
 Sweet was the draught, and sweet the blooming maid,
 Who touch'd her lyre beneath the fragrant shade.

Sir W. Jones.

There seems a floating whisper on the hill,
 But that is fancy, for the starlight dews,
 All silently their tears of love instil,
 Weeping themselves *away*, till they infuse
 Deep into Nature's breast the spirit of her hues.

Lord Byron's Child Harold.

AWE', v. & n.

AWE'FUL,

AWE'FULLY,

AWE'FULNESS,

AWE'LESS,

AWE'LESSLY,

AWE'LESSNESS,

AWE'-STRUCK.

Goth. agyan, to fear,
 or dread. To cause
 fear, terror, or reve-
 rence.

His coward lips did from their colour fly,
 And that same eye, whose bend does *awe* the world,
 Did lose its lustre.

Shakspeare.

Know, then, that some of us are gentlemen,
 Such as the fury of ungovern'd youth
 Thrust from the company of *awful* men. *Id.*
 So *awful*, that with honour thou may'st love
 Thy mate; who sees, when thou art seen least wise.

Milton. Par. Lost.

I approach thee thus, and gaze
 Insatiate; I thus single; nor have fear'd
 Thy *awful* brow, more *awful* thus retir'd,
 Fairest resemblance of thy Maker fair. *Id.*

A parish priest was of the pilgrim train,
 An *awful*, reverend, and religious man,
 His eyes diffus'd a venerable grace,
 And charity itself was in his face. *Dryden.*

Hail! rev'rend priest! To Phœbus' *awful* dom:
 A suppliant I, from great Atrides come,
 Unransom'd here receive the spotless fair,
 Accept the hecatomb the Greeks prepare. *Pope.*

In those deep solitudes, and *awful* cells,
 Where heav'nly-pensive contemplation dwells,
 And ever-musing melancholy reigns.
Id. Eloisa to Abelard.

In winter, *awful* thou! with clouds and storms
 Around thee thrown, tempest o'er tempest roll'd
 Majestic darkness! on the whirlwind's wing,
 Riding sublime, thou bidst the world adore
 And humblest nature with thy northern blast.

Thomson.

Serene, though *awful*, on her brow the light
 Of heavenly wisdom shone; nor roved her eyes,
 Save to the shadowy cliff's majestic height,
 Or the blue concave of th' involving skies.

Beattie.

It were endless to enumerate all the passages, both
 in the sacred and profane writers, which establish the
 general sentiment of mankind concerning the insepara-
 ble union of a sacred and reverential *awe* with our
 ideas of the divinity.

Burke.

A-WEIGH, the state of an anchor when it is
 drawn out of the ground in a perpendicular
 direction.

AWERI, or **OVERO**, a kingdom of Africa, de-
 pendent on Benin, with a town of the same name
 on the river Formosa.

AWE'ARY. On weary. See **WEARY**.

SAP. Go thy waies, I begin to be *awearie* of thee;
 and I tell thee so before; because I would not fall out
 with thee.

Shakspeare. All's Well that Ends Well.

AWIA'PED. From Ang.-Sax. wafian, to be
 amazed, or astonished, terrified, confounded.

Ah! my dear gossip, answer'd'then the ape,
 Deeply do your sad words my wits *awhape*,
 Both for because your grief doth great appear,
 And eke because myself am touched near.

Hubberd's Tale

AWIEELS. ON **WHEELS**.

And will they not cry then the world runs *awheels*.

Ben Jonson's Masques, f. 18.

AWHILE'. A time; Ang.-Sax. hwile (for
 hwiol, a turn), walk a while, take a turn. See
WHILE.

Stay, stay, I say:

And if you love me, as you say you do,
 Let me persuade you to forbear *awhile*.

Shakspeare

Into this wild abyss the wary fiend
 Stood on the brink of hell, and look'd *awhile*,
 Pond'ring his voyage. *Milton's Paradise Lost*

Here, lonely wandering, o'er the sylvan bower,
 I come to pass the meditative hour;
 To bid *awhile* the strife of passion cease,
 And woo the calms of solitude and peace.

Kirke White's Poems.

But thou, with spirit frail and light,
Wilt shine *awhile* and pass away,
As glow-worms sparkle through the night,
But dare not stand the test of day.

Lord Byron.

AWHIT'. A whit, or o whit, Ang.-Sax. hwit.
See **WHIT.**

These farre exceede the haggarde hauke
That stoppeth to no stale :
Nor forceth on the lure *awhit*,
But mounts with eu'ry gale ?

Turberville. Epitaphes, &c.

AWK',
AWK'LY,
AWK'WARD,
AWK'WARDLY,
AWK'WARDNESS. } Perhaps awk is a corruption of averricht. The termination, ward, is from keered, past participle of keeren, Ang.-Sax. cyrran, to turn. Deviating from the right path or line, indirect, clumsy, inelegant.

Proud Italy,

Whose manners still our tardy apish nation
Limps after in base *awkward* imitation.

Shakspeare.

Their own language is worthy their care; and they are judged of by their handsome or *awkward* way of expressing themselves in it.

Locke.

An *awkward* shame, or fear of ill usage, has a share in this conduct.

Swift.

Slow to resolve, but in performance quick;

So true, that he was *awkward* at a trick.

Dryden.

It is an *awkward* thing for a man to print in defence of his own work against a chimæra: you know not who or what you fight against.

Pope.

What's a fine person, or a beauteous face,
Unless deportment gives them decent grace ?

Bless'd with all other requisites to please,
Some want the striking elegance of ease;
The curious eye their *awkward* movement tires;
They seem like puppets led about by wires.

Churchill.

AWK, in ornithology. See **ALCA.**

AWL'. Ger. ahl. A sharp pointed tool. In the chronicles used for a weapon of war.

His *aule* and lingell in a thong,
His tar-boxe on his broad belt hong,
His breech of coyntrie blew.

Drayton.

Thou art a cobler, art thou ?

Truly, sir, all that I live by is the *awle*.

Shakspeare. Julius Cæsar, fol. 109.

AWLS, among shoemakers, are usually a little flat and bended in the blade, and the point ground to an acute angle.

AWLAN, a small imperial town of Germany, in the circle of Suabia, seated on the river Kocher, fifteen miles west of Oeting and twelve north of Heidenheim.

AWME, or **AUME**, a Dutch measure of capacity for liquids, containing eight steckans, or twenty verges or verteels; answering to what in England is called a tierce, or one-sixth of a ton of France, or one-seventh of an English ton. Arbutnot.

AWN, in botany. See **ARISTA.**

AWN of wine, 360 pounds.

AWNING. A cover spread over a boat or vessel, to keep off the weather.—Awnings are made of canvas. The length of the main-deck awning, says Mr. Clerke, is from the centre of the fore-mast to the centre of the main-mast; the

width corresponds to the breadths of the ship, taken at the main-mast, fore-mast, and at the mid-way between. The length of the quarter-deck awning is from the centre of the main-mast to the centre of the mizen-mast; and the width answers to the breadths of the ship, at the main-mast, mizen-mast, and at the mid-way between. The length of the poop, or after-awning, is from the centre of the mizen-mast to the ensign-staff, about seven feet above the deck; and the width is formed agreeably to the breadths of the ship, taken at the mizen-mast, the taffarel, and at the mid-way between. The canvas is cut to the given breadths of the awning, allowing about nine inches to hang down on each side, which is sometimes scolloped and bound with green baize, and is sewed together with an inch-seam, and tabled all round with a two or three inch tabling. Half the diameter of the masts is cut out in the middle at each end, and lacing-holes are made across the ends to connect one awning to another. On the upper part, along the middle and sides, is sewed a one-inch and half or two-inch rope, to which the trucks are sewed at about three-quarters of a yard asunder. A thimble is spliced in each end of the rope. Sometimes curtains are made to hang to the sides of the awnings, of the same length as the awnings. Their depth is taken from the sides of the awning to the gun-wale, supposing the awning to be in its place. The seams and tablings are the same as those of the awnings, and lacing-holes are made along the upper tabling of the curtain, and the side tabling of the awning. Clerke's Elem. and Practice of Rigging, vol. i. p. 140. 230. In the long-boat they make an awning, by bringing the sail over the yard and stay, and booming it out with the boat-hook.

AWOR'K, } In work. See **WORK.**
AWOR'K'ING. }

Long they thus trauail'd, yet neuer met
Adventure, which might them *aworking* set.

Spenser. Mother Hubbard's Tale.

He first suborns a villain, that embrac'd
The nobler name of March-born Mortimer,
Which, in the title of the house of York,
Might set the monstrous multitude *awork*.

Drayton. Miseries of Queen Margaret.

Who shoulde bee the makers of anye maner cloth,
if there lacked men of substauce to set sūdry sortes
a *woorke*.

Sir Thomas More's Workes.

AWRE'KE. Ang.-Sax. awrecan, to wreak.
See **WREAK.**

Than dame Prudence, whan that she saw how that
hire husbände shope him for to *awreke* him on his
foos, and to beginne werre, she in ful humble wise,
whan she saw hire time, sayde him these wordes.

Chaucer. The Tale of Melibeus.

AWRISH, a river in the county of Durham, which runs into the Tees at Eggleton.

AWRY'. Past participle awrythed, of the verb wrythan, to writhe. Wriathed, crooked, bended, distorted, askance.

When I look back, and in myself behold

The wand'ring ways, that youth could not descry :

And see the fearful course that youth did hold,

And mete in mind each step I strayed *awry*.

Paradise of Dainty Devices, 1600.

Preventing fate directs the lance *awry*,
Which glancing only mark'd Achilles' thigh.

Dryden.

AX, } Ask, Asking. See Ask. These
AX'YNG. } words, which are now considered
vulgarisms, are the original Saxon forms.

But Robin may not wete of this, thy knave,
Ne eke thy maiden Gille I may not save;
Aze not why; for though thou *are* me,
I wol not tellen goddes privetees.

Chaucer. The Miller's Tale, v. i. p. 140.

AX, a town of France, the head of a canton, in the department of the Arriège, arrondissement of Foix. Here are warm baths which are much frequented. It lies on the river Arriège. Five leagues north-west of Tarascon. Population 1500.

AX, or AXE, a river of England, which rises in the county of Dorset, and entering Devonshire, passes by Axminster, and afterwards falls into the sea a little below Axmouth.

AX, a river of England, which rises in Wokey-Hole, near Wells, in the county of Somerset, and after passing Axbridge, falls into the Bristol channel, about eight miles lower down.

AX, BATTLE. See AXE.

AXAM, a district and town of Tyrol, in the lower valley of the Inn, to the south-west of Innspruck. Here a great deal of flax is cultivated.

AXAMENTA, in antiquity, the verses or songs of the salii, which they sung in honor of all men. The word is formed, according to some, from axare, to nominate. Others will have the carmina salaria to have been denominated axamenta, on account of their having been written in axibus, or on wooden tables. The axamenta were not composed by the salii. The author of them was Numa Pompilius; and, as the style might not be altered, they grew in time so obscure, that the salii themselves did not understand them. Varro says they were 700 years old.

AXAMENIA, or ASSAMENIA, in ancient music, hymns performed wholly with human voices.

AXARA, a town of Asiatic Turkey, in Naxolia, situated in a fertile district of the same name, fifty or sixty miles from Gizeel-Hissar.

AXATH, a town of ancient Bactria, in the Bactis; now called Lora, a small city of Andalusia, in Spain, seated on the Guadalquivir.

AXAYACAFI, a species of fly, common about the lakes of Mexico; the eggs of which, being deposited in immense quantities upon the rushes and corn-cobs, form large masses, which are taken up by fishermen, and carried to market. This caviare, called *axayacafi*, which has much the same taste with the caviare of fish, used to be eaten by the Mexicans, and is now a common dish among the Spaniards. The Mexicans eat not only the eggs, but the flies themselves, made up together into a mass, and prepared with saltpeper.

AXBURY, a market town of Somersetshire, and is so named, by prescription, sending a man to parliament during the reigns of the first three Edwards, after which it was, at its own desire, excused. The corporation consists of a mayor, a clerk, a town clerk, ten aldermen, and twenty-four burgesses, of whom a sheriff, serjeant-at-law, and two justices are chosen.

Knit hose is the only manufactory. The kings of England formerly had a hunting chase here Market on Saturday. It is twenty-three miles north-west of Somerton, and 131 west of London.
AXE. Gr. $\lambda\gamma\omega$, $a\zeta\omega$. An adze or addice. See ADDICE.

My mangled body shows,
My blood, my want of strength, my sick heart shows
That I must yield my body to the earth,
And by my fall the conquest to my foe;
Thus yields the cedar to the *axe's* edge,
Whose arms give shelter to the princely eagle.

Shakspeare. Third Part of Henry VI. act v. sc. 3.
Loud sounds the *axe*, redoubling strokes on strokes,
On all sides round the forest hurls her oaks
Headlong. Deep echoing groan the thickets broken,
Then rustling, crackling, crashing, thunder down.

Pope's Homer's Iliad, xxiii. 144.

Like crowded forest trees we stand,

And some are mark'd to fall;

The *axe* will smite at God's command,

And soon will level all.

Cowper.

AXE, a river in Somersetshire, which falls into the Severn below Uphill.

AXE, or AX, differs from the hatchet, in that it is made larger and heavier, to have large stuff; and its edge tapering into the middle of its blade. It is furnished with a long handle, being to be used with both hands.

AXEL, or AXIL, a small fortified town of Dutch Flanders, in the kingdom of the Netherlands. It is seated among marshes, fourteen miles north of Ghent.

AXELODUNUM, the ancient name of Hexham, in Northumberland.

AXENUS, the ancient name of the Euxine Sea, the signification of which is, inhospitable; and is perfectly answerable to the disposition and manners of the ancient inhabitants of the east.

AXE-STONE, in mineralogy, a sub-species of jade, but not of so light a green, and somewhat of a slaty texture. The natives of New Zealand work it into hatchets. It is found in Corsica, Switzerland, Saxony, and on the banks of the river Amazons, whence it has been called Amazonian stone. Its constituents are silica 50.5, magnesia 31, alumina 10, oxide of iron 5.5, water 2.75, oxide of chromium 0.05.

AXEY, the principal town in the island of Axholm. It is thinly inhabited.

AXHOLM, a river island in the north-west part of Lincolnshire. It is formed by the rivers Trent, Idel, and Dun; and is about ten miles long, five broad, and twenty in compass. It has three villages, Crowle, Epworth, and Hyrst; besides Axey, the chief town. The lower part is marshy, but produces an odoriferous shrub, called gall; the middle is rich and fruitful, yielding flax in great abundance. It also produces an alabaster, which is used for making lime. In the eighteenth century the body of a woman, quite entire, and in a bent position, the head and feet almost in contact, was found in a morass, which, from the fashion of her sandals, was conjectured to have lain there from the time of Edward I. when there were two monasteries here.

AXIACE, an ancient town of Sarmatia Europea; now Oczacow.

AXIL. See AXEL.

AXILLA, in anatomy, or ALA, the cavity under the upper-part of the arm; commonly called the arm-pit. It is a diminutive of axis, q. d. little axis. Abscesses in the axillæ are usually dangerous on account of the many blood-vessels, lymphatics, nerves, &c. thereabout, which form several large plexuses. By the ancient laws, criminals were to be hanged by the axillæ if they were under the age of puberty.

AXILLA, in botany, is the space comprehended between the stems of plants and their leaves. Hence we say, those flowers grow in the axillæ of the leaves; i. e. at the base of the leaves, or just within the angles of their pedicles.

AXILLARY ARTERY is that part of the subclavian branch of the ascending trunk of the aorta, which passes under the arm-pits.

AXILLARY GLANDS are situated under the arm-pits, enveloped in fat, and lie close by the axillary vessels.

AXILLARY NERVE, called also the auricular nerve, arises from the last two cervical pairs; runs into the hollow of the axilla, behind the head of the os humeri, between the musculus teres major and minor, &c.

AXILLARY VEIN, is one of the subclavian veins; which, passing under the arm-pits, divides itself into several branches; superior, inferior, external, internal, &c. which are spread over the arm.

AXILLARY VERTEBRA, the second vertebra of the back, so called because it is nearest to the arm-pits.

AXIM, a district of Africa, part of the fertile territory of Ahanta, on the Gold Coast. It is directly east of Apollonia, from which it is separated by the river Ancobra. The Dutch have a fort in Axim called Fort Anthony, situated on the most western promontory of Cape Three Points. It is compact, well situated for landing, and in a commanding position. Ten leagues east of Apollonia.

The climate is so excessively moist, that it is proverbially said to rain eleven months and twenty-nine days of the year. This excessive moisture renders it very unhealthy; but it produces great quantities of rice, water-melons, lemons, oranges, &c. Here are also produced vast numbers of black cattle, goats, sheep, pigeons, &c. The whole country is filled with beautiful and populous villages, and the intermediate lands are well cultivated. The natives all go naked, but are very healthy; and there is a constant traffic carried on with them by the Europeans for their gold. This canton is a kind of republic, the government being divided between the Caboceroes or chief men, and Manaceroes or young men. But in their courts, whoever makes the most valuable present to the judges is sure to gain his cause. The Portuguese founded the first settlement here, but were driven from it by the Dutch in 1642.

AXIM, a river in the above canton, which runs through the town of Axim.

AXIM, or Auchombone, the capital of Axim, stands under the cannon of the Dutch fort St. Antonio. It is secured behind by a thick wood that covers the whole declivity of a neighbouring

hill. Between the town and the sea runs an even and spacious shore of beautiful white sand. All the houses are separated by groves of cocoa, and other fruit-trees, planted in parallel lines, each of an equal width, and forming an elegant vista. The coast is defended by a number of small pointed rocks, which project from the shore, and render all access to it dangerous.

AXINAEÆ, AXINÆÆ, in natural history, a genus of the Mollusca tribe (Testacea,) established by Poli, in his history of the shells of the two Sicilies. The character is taken from the form of the animal; the shell belongs to the Arca genus of the Linnæan arrangement.

AXINITE, in mineralogy, a crystallised substance, found principally in Dauphiny, in France, and latterly in the neighbourhood of St. Just. Cornwall. The colors are a light violet brown. The crystals resemble an axe in the form and sharpness of their edges; being flat rhomboidal parallelepipeds, with two of the opposite edges wanting, and a small face instead of each. They become electric by heat. Lustre splendid. Hard, but yields to the file, and easily broken. Specific gravity 3.25. It froths like zeolite before the blow-pipe, melting into a black enamel, or a dark green glass. According to Vauquelin's analysis, it contains forty-four silica, eighteen alumina, nineteen lime, fourteen oxide of iron, and four oxide of manganese.

AXINOMANCY, AXINOMANTIA; from ἀξίωη, an axe, and μαντεία, divination; an ancient species of divination, or a method of foretelling future events by means of an axe or hatchet. This art was in considerable repute among the ancients; and was performed, according to some, by laying an agate stone on a red hot hatchet, and also by fixing a hatchet on a round stake so as to be exactly poised; then the names of those that were suspected were repeated, and he at whose name the hatchet moved was pronounced guilty.

AXIOM, } Gr. Ἀξίωμα, from ἀξίω, }
AXIOMATICAL. } to think worthy. A self-
evident proposition.

The universal axiom in which all complaisance is included, is, that no man should give any preference to himself.

Johnson.

That a conjectural critic should often be mistaken, cannot be wonderful, either to others or himself, if it be considered that in his art there is no system, no principal and axiomatical truth that regulates subordinate positions.

Johnson's Preface to Shakespeare.

AXIOM, in rhetoric, is used by Hermogenes to denote grandeur, dignity, and sublimity of style.

AXIOMS, in logic. That the whole is greater than a part; that a thing cannot be, and not be at the same time; and that from nothing, nothing can arise; are axioms indisputable. Established principles in arts and sciences are also stiled axioms. Thus it is an axiom in physics, that nature does nothing in vain; that effects are proportional to their causes, &c. It is an axiom in geometry, that things equal to the same thing, are also equal to one another; that if to equal things you add equals, the sums will be equal, &c. It is an axiom in optics, that the angle of

incidence is equal to the angle of reflection, &c.

AXION, the brother of Alpheisbæa, who murdered Alcmaeon, his sister's husband, because he wished to take back a golden necklace he had given her.

AXIOPOLI, a town in Bulgaria. Long. 34° 0' E., lat. 45° 40' N. It was formerly called **AXIOPOLIS**; a town of the Triballi, in Mæssia Interior.

AXIOS, a form of acclamation, anciently used by the people in the election of bishops. When they were all unanimous, they cried out *αξιος!* he is worthy! or *αναξιος!* unworthy!

AXIOSIS, *αξιωση*, in rhetoric, denotes the third part of an exordium; sometimes called *αποδοσις*, and containing some new proposition more nearly relating to the subject, than the *προτασις*. Thus in Cicero's oration, pro Milone, the protasis is, Non possum non timere, judices, *visa hæc nova judicii forma*: the katasæue, Nec enim ea corona confensus vester cinctus est qua solebat: the axisis, Sed me recreat Pompei consilium, *cujus sapientiæ non fuerit, quem sententiis judicium tradidit, telis militum dedere*: the basis, *Quamobrem adeste animis judices, et timorem, si quam habetis, deponite*.

AXIOTEA, or **AXIOTHEA**, a female philosopher of Greece, who lived in the time of Plato, and attended his lectures, dressed in the habit of a man.

AXIS,
AXLE,
AXLEFD.
AXLE-TREE.

Lat. *axis*, Gr. *αξων*, from *αξεν*, to go round. Axis is a line drawn through the centre of any body round which it revolves.

The line, that we devise from thence to thother so,
 As *axell* is; upon which the heaven's about do go.

Wyatt.

But mark me also, these mouinges of these seuen,
 Be not alone the *axeltree* of the first mouing heauen.

Id.

Inferior ministers, for Mars repair
 His broken *axle-trees*, and blunted war.

Dryden. Virgil's Æneid. viii.

And bade her spirits bear him far,
 In Merlin's *agate-axled* car,
 To her green isle's enamelled steep,
 Far in the navel of the deep.

T. Warton. The Grave of King Arthur.

AXIS, in anatomy, the second vertebra of the neck, thus called because the first vertebra with the head, moves thereon, as on an axis.

AXIS, in astronomy, is an imaginary right line supposed to pass through the centre of the heavenly bodies, about which they perform their diurnal revolutions.

AXIS, in botany, a taper column placed in the centre of some flowers or catkins, about which the other parts are disposed.

AXIS, in comic sections, a right line dividing the section into two equal parts, and cutting all its ordinates at right angles.

AXIS, in geometry, the straight line in a plain figure, about which it revolves, to produce or generate a solid. Thus if a semicircle be moved round its diameter at rest, it will generate a sphere, the axis of which is that diameter.

AXIS, in mechanics. The axis of a balance is that line which it moves, or rather turns about.

AXIS, in optics, is that particular ray of light coming from any object which falls perpendicularly on the eye.

AXIS, common or mean, in optics, a right line drawn from the point of concourse from the two optic nerves, through the middle of the right line which joins their extremity.

AXIS, in peritrochio, one of the six mechanical powers, consisting of a peritrochium or wheel concentric with the base of a cylinder, and moveable together with it about its axis.

AXIS, in zoology, a very remarkable animal, of the deer kind in all respects, except that neither the male nor female have horns; the tail is considerably long, and the whole shape and make are extremely like those of the fallow deer. The female is smaller than the male, and both are of a reddish tawny color, variegated with spots of white; the belly is white. The voice is much more loud and shrill than that of the deer. It is plain that this creature is neither of the red nor fallow deer kind, whence Bellonius, who saw it at Cairo in Egypt, was induced to call it the Axis.

AXIS, determinate, in a hyperbola, a right line which divides it into two equal parts, and at right angles, an infinite number of lines drawn parallel to each other within the hyperbola.

AXIS, **MAGNETICAL**, or **AXIS OF A MAGNET**, a line passing through the middle of a magnet, lengthways, in such manner, as that however the magnet be divided, provided the division be made according to a plane wherein such line is found, the load-stone will be made into two load-stones. The extremities of such lines are called the poles of the stone.

AXIS OF A PLANET, is a line drawn through the centre, about which the planet revolves. The sun, moon, and all the planets, except Mercury and Saturn, are known, by observation, to move about their several axes; and the like motion is easily inferred from those two.

AXIS OF A SPHERE, or **CIRCLE**, is the same as diameter.

AXIS OF A VESSEL, is an imaginary right line passing through the middle of it perpendicularly to its base, and equally distant from its sides.

AXIS OF INCIDENCE in dioptrics, a right line drawn through the point of incidence perpendicular to the refracting surface.

AXIS OF OSCILLATION, is a right line parallel to the horizon, passing through the centre about which a pendulum vibrates.

AXIS OF REFRACTION, is that which is made by the ray of incidence directly prolonged on the inside of the second medium by the ray of refraction.

AXIS OF THE CYLINDER, is properly that quiescent right line, about which the parallelogram turns, by whose revolution the cylinder is formed. Though, both in right and oblique cylinders, the right line joining the centres of the opposite bases, is also called the axis of the cylinder.

AXIS OF THE EARTH, is a right line upon which the earth performs its diurnal rotation from west to east.

AXIS OF THE IONIC CAPITAL, is a line passing perpendicularly through the middle of the eye of the volute.

AXIS OF THE ZODIAC, a line supposed to pass through the earth and terminate in the poles.

AXIS, SPIRAL, is the axis of a twisted column drawn spirally, in order to trace the circumvolutions without.

AXMINSTER, a town of Devonshire, situated on the river Ax, in the great road between London and Exeter, being twenty-five miles east of the latter place. It was a place of some note in the time of the Saxons, and now contains about 2500 inhabitants. It has a manufactory of broad and narrow cloths, and an extensive one of carpets, manufactured after the Turkish manner: its carpets are often preferred to those from Turkey. The petty sessions are holden here. King Æthelstan founded a minster here, for seven priests, to pray for the souls of those who were slain in a battle which he fought with the Danes at Bremaldown. It has four fairs: on the 24th of February, 25th of April, 24th of June, and Wednesday after Michaelmas, with a market on Saturday. It is 147 miles west of London. Long. 3° 8' W., lat. 50° 45' N.

AXOLOTI, in ichthyology, a singular fish found in the lakes of Mexico. It has four feet like the lizard, no scales, a matrix like a woman, and the menstrual flux. It has the taste of an eel.

AXONES; *αξωνες*; public laws of the ancient Greeks, particularly of the Athenians, so named from their mode of publication.

AXTEL (Daniel), a regicide, and colonel in the service of the long parliament, was of a good family, and had a tolerable education. As he was of a serious disposition, and had been very early tinctured with puritanical principles, he became a fervent follower of such ministers as distinguished themselves by their zealous preaching. His great attachment to these people, and the natural warmth of his temper, were the cause of his going into the army, in which he behaved with so much zeal, courage, and conduct, that he rose by degrees to the several commands of captain, major, and lieutenant-colonel, in a regiment of foot. It was in this last capacity that he acted with great vehemence against all endeavours for a reconciliation with the king. When the king was brought before the high court of justice, colonel Stubberd and Axtel had the command of the soldiers below stairs. The king demanded of sergeant Bradshaw, the president, by what authority they brought him there? and the president appealing to the charge, which was in the name of the Commons of England, lady Fairfax and Mrs. Nelson are said to have cried out, 'It is false; not a half, not a quarter of the people.' Upon this colonel Axtel cried out, 'Down with the w——; snoot them!' After the sentence, the king was carried through King-street, in a sedan, by two porters, who, out of reverence, went bare-headed, till the soldiers under Axtel's command beat them, and forced them to put on their hats. After the king's death, when Cromwell was sent into Ireland, the regiment in which Axtel served was drawn out by lot for that expedition, which occasioned his going over into that kingdom, where he made a considerable figure, was much esteemed, and raised by Cromwell to the command of a regiment, and the go-

vernment of Kilkenny. After the Protector's death Axtel endeavoured to conceal himself, suspecting that he might be called to an account for the share he had taken in the trial of the king; but before the close of the month he was discovered and committed to prison. On the 10th of October the grand jury for Middlesex found bills against twenty-eight persons, for their concern in the king's death, of whom Axtel was the last. His trial, by the elaborate defence he made, lasted upwards of three hours: but the jury, without going from the bar, found him guilty; and he was executed, on the 19th, at Tyburn.

AXUM, *ΑΧΟΜΑ*, *ΑΧΟΜΙΣ*, or *AKSUM*, in Abyssinia, the capital of a powerful state in the time of the Ptolemies, and perhaps of all Abyssinia; still retaining monuments of its former splendor. An ancient throne of granite, and two rows of obelisks, struck Mr. Salt as amongst the most beautiful ancient relics he had ever seen. But perhaps the most curious of all is a long Greek inscription, which records the victories of one of the Ptolemies and the extent of their empire. Frumentius, the apostle of Ethiopia, was the first bishop of Axum, and many churches had been excavated from the surrounding mountains before the close of the fifth century. It carried on a considerable trade with India and Arabia, through the port of Adulis. It is the place where the kings of Abyssinia are crowned. Mr. Salt found it to be in lat. 14° 6' 36" N. Its present population is about 3000. The inhabitants are rude and inhospitable. They wear coarse woollen clothes. The monks prepare the best parchment in all Abyssinia. The church of Axum appears to have been built in 1657, and is considered by Mr. Salt, excepting that of Chelicut, as the finest in the province of Tigré. The town stands agreeably sheltered by hills, at the corner of an extensive valley. It is described by Bruce as containing 600 houses.

AXUNGIA, in a general sense, denotes old lard, or the driest and hardest of any fat in the bodies of animals; but more properly it signifies only hog's lard.

AXUNNYIA LUNE, an affected name given by the German chemists to the terra goltbergensis, from their imagining that it contains some particles of silver, and owes to them its virtues in medicine.

AXUNGIA SOLIS is used for the terra silesiaca, and said to be good against the plague, pestilential fevers, &c.

AXUNGIA VITRI, **SANDIVER**, or salt of glass, a kind of salt which separates from the glass while it is in fusion. It is of an acrimonious and biting taste. The farriers use it for cleansing the eyes of horses. It is also made use of for cleansing the teeth; and it is sometimes applied to running ulcers, the herpes, or the itch, by way of desiccative.

AXYLUS, an ancient hero of Arisba, celebrated by Homer for his hospitality, which gained him the appellation of the Friend of Mankind.

AXYRIS, a genus of the triandria order, and monœcia class of plants, ranking in the natural method under the twelfth order holoracæ. The

calyx of the male is tripartite; it has no corolla. The calyx of the female consists of two leaves; it has two styli and one seed.

AY. Sax. Ever. For ever.

AY, a town of France, in the department of Marne, near the river Marne, remarkable for its excellent wines. It lies twelve miles south of Rheims, and one mile and a half north-east of Epernay. Inhabitants 2600.

AYACUCHO, BATTLE OF. This engagement is one of the most celebrated in the history of South America, having been decisive of the independence of Upper and Lower Peru. For several months before this event, the Colombian auxiliary army, under general Sucre, and the royalist army, under the viceroy La Serna, had been moving in face of each other with various success, but, on the whole, to the disadvantage of the Colombians. Sucre and his men were anxious for battle; and at length La Serna determined to engage them on the plain of Ayacucho, Dec. 9, 1825. The royalist force consisted of 9,310 men, that of the patriots of 5,780 men. Generals Sucre (the commander in chief), La Mar, Cordova, and Miller distinguished themselves on this occasion, and the battle terminated in the total defeat of La Serna, who was taken prisoner, with the loss of 1800 men in killed and wounded, and in the capitulation of Cacerac, the second in command. Of the patriots, only 370 were killed. This splendid victory effectually accomplished the delivery of Peru from the Spaniards.

AYAG, or KAYACH, one of the Andrenofskie islands, in the eastern or Pacific Ocean, about 150 versts in circumference, and consisting of several high and rocky mountains, the intervals of which are bare heath and moor ground; but in the whole island there is not one forest-tree.

AYAMONTE, a sea-port town of Andalusia in Spain, with a strong castle built on a rock; seated on the mouth of the Guadiana, eighty-five miles north-west of Cadiz. It has a commodious harbour, a productive sardel fishery, fruitful vineyards, and excellent wine. Population about 5300.

AYAS, a town and castle of Caramania, in the government of Adana, on the bay of Ayas, near the Jypoo, and on the west side of the Gulf of Scanderoon, or Iskenderoon, the ancient Sims Issicus. It is fortified all round; and here are the remains of a fort and artificial pier. A little to the westward is a round tower with an Arabic inscription. Myriads of fish, numerous fine turtle, and aquatic birds, abound on the shore. This place is supposed to be the ancient Egea. Long. 25° 48' E., lat. 36° 46' N.

AYASHI, a village on the same coast, surrounded by the ruins of a town that has occupied a considerable space of ground, and containing the remains of a theatre and many other edifices. The most conspicuous of the whole is a temple, situated on a projecting eminence. Its columns are of the composite order, fluted, and about four feet in diameter. This is conjectured to have been the ancient Sebasta.

AYAVIRI, a town of Lima, in Peru, remarkable for many stately tombs of the Peruvian nobility.

AYBAR, a town of Spain, in Navarre, on the Arragon, famous for a battle fought here in the year 1451, between John king of Castile, and his son Don Carlos, in which the latter was defeated and taken prisoner. Three miles south of Sanguesa.

AYDON BRIDGE, or HEYDON BRIDGE, a town in Northumberland, five miles west of Hexham, so named from its bridge over the Tyne. It has a market on Tuesday, and a fair on July 21st, 22d, and 24th.

AYE. *Ayez*. The imperative of the French verb *avoir*, to have; signifying have it, possess it, enjoy it. The expression is similar in Swedish, German, and Dutch.

Return you thither?

Ay, madam, with the swiftest wing of speed.

Shakspeare.

What say'st thou? wilt thou be of our consort?
Say *ay*, and be the captain of us all.

Id.

Sometimes in mutual sly disguise,
Let *ayes* seem *nos*, and *nos* seem *ayes*;
Ayes be in courts denials meant,
And *nos* in bishops give consent.
Thus *aye* proposed, and, for reply,
No for the first time answer'd *aye*.
They parted with a thousand kisses,
And fight e'er since for pay like Swisses.

Gay's Fables. Aye and No.

AYEK JEMANI, a species of cornelian, much valued by the Arabians.

AYEL, Fr. in law, a writ which lies where the grandfather was seized in his demesne on the day he died, a stranger enters the same day and dispossesses the heir.

AYEN, } See AGAIN.
AYENST, }

AYENIA, in botany, a genus of the pentandria order and gynandria class of plants, ranking in the natural method under the thirty-seventh order, columniferae. The calyx has two leaves; the petals are in the form of a star, with long ungues; and the capsule has five cells. There are three species all natives of the West Indies.

AYERBE, or AYERVE, the capital of a barony, in the district of Huesca, Arragon, situated at the foot of the Pyrenees, thirty-two miles north of Saragossa.

AYERSTOWN, a town of the United States, in New Jersey, thirteen miles south-east from Burlington.

AYESHA, the wife of Mahomet, and daughter of Abubeker. The impostor had a greater regard for her than for any of his wives, though she had no children; and his followers highly respected her. She opposed Ali's succession and raised an army against him; but after a severe contest was made prisoner. The conqueror, however, dismissed her with civility. This turbulent woman died in 677, aged sixty-seven.

AYGULA, in zoology, a species of simia or ape.

AYGULUS, in entomology, a species of scarabæus that inhabits India.

AYLESBURY (Sir Thomas), merits a place in a work of this kind, not only as a learned man himself, but as the patron of men of letters. He was born in London in 1576, was educated

at Westminster, and studied at Oxford, where he took his degree of A.M. in 1605. He became secretary to Charles earl of Nottingham, lord high admiral, and gave so many proofs of his skill in mathematics, that he retained his secretaryship under the duke of Buckingham upon his succeeding the earl. By the duke's influence he was appointed master of requests, and master of the mint, and created a baronet. The profits of these lucrative offices he applied to the most benevolent purposes. He not only made all men of science welcome to his table and afforded them his best countenance, but also gave regular pensions to such of them as were in narrow circumstances. It is to be regretted that a man of so benevolent a character should himself have afterwards experienced adversity. In consequence of his steady adherence to the king, he was, in 1642, stripped of his places and estate, but he bore up cheerfully under his misfortunes, and in 1649 retired with his family to Brussels. He died at Breda in 1657, aged eighty-one.

AYLESBURY (William), the son of the baronet, took his degree of A.M. at Christ Church, in the sixteenth year of his age, and like his father, was a sufferer by his adherence to the cause of royalty. King Charles I. early appointed him travelling preceptor to George Villiers duke of Buckingham, and his brother, Lord Francis. During their travels in Italy he was nearly killed by an assassin. He returned to England during the civil war, but after the king's death retired to Antwerp. In 1650 he again returned to England, where he experienced great difficulties, being often in want of daily necessaries. At last, in 1657, the protector having fitted out a fleet for the West Indies, he was engaged as secretary to the governor of Jamaica, the climate of which soon cut him off.

AYLESBURY. See **AYLESBURY.**

AYLESFORD. See **AYLESFORD.**

AYLETS, or SEA SWALLOWES. In heraldry, they are often called Cornish choughs, and are painted sable, beaked, and legged gules.

AYLETT (Robert), an English author of the seventeenth century. He was educated at Trinity Hall, Cambridge, where he took the degree of LL.D. in 1614, and afterwards became master in Chancery. He wrote *Susanna, or the Arraignment of the Two Elders*, a poem, 1622, 8vo. besides several other poetical pieces. He is thought by some to have been the author of the *Britannica Antiqua Illustrata*, which is generally attributed to his nephew, Aylett Sammes.

AYLIN (John), an Italian writer of the fourteenth century. His chief work is a History of Friuli, printed in Muratori's *Antiquitates Italice mediæ ævi*, Milan, 1740.

AYLMER (John), bishop of London in the reign of Elizabeth, was born in 1521, at Aylmer-hall, in Tilney, Norfolk. While a boy he was distinguished for his quick parts, by the marquis of Dorset, afterwards duke of Suffolk; who sent him to Cambridge, made him his chaplain, and tutor to his children. One of these was the unfortunate Lady Jane Gray, who soon became perfectly acquainted with the Latin and Greek. His first preferment was to the archdeaconry of Stow, which gave him a seat in the convocation

held in the first year of queen Mary, where he resolutely opposed the return to popery, to which the generality of the clergy were inclined. He was soon after obliged to take shelter among the Protestants in Switzerland. On the accession of Elizabeth he returned to England. In 1562 he obtained the archdeaconry of Lincoln; and was a member of the famous synod of that year, which reformed and settled the doctrine and discipline of the church of England. In 1576 he was consecrated bishop of London. He died in 1594, aged seventy-three; and was buried in St. Paul's. He published *An Harbrowe for faithful and trewe Subjects against the late blowne Blaste concerning the Government of Women, &c.* In answer to Knox, who published a book at Geneva under this title, *The first Blast against the monstrous Regimen and Empire of Women.* Strype gives the following instance of his courtly courage:—Queen Elizabeth being once tormented with the tooth-ache, and yet afraid of having the tooth drawn, bishop Aylmer being by, to encourage her majesty, sat down in a chair, and calling to the operator, 'Come,' said he, 'though I am an old man, and have but few teeth to spare, draw me this;' which was done; and the queen seeing him make so slight a matter of it, sat down and had hers drawn also.

AYLOFFE (Sir Joseph), of Framfield in Sussex, was descended from a Saxon family anciently seated at Bocton Aylf, in Kent, in the reign of Henry the Third. He was born about 1708; received the early part of his education at Westminster school; admitted of Lincoln's Inn 1724; and in the same year was entered a gentleman commoner at Oxford, which he quitted about 1728; was elected F.A.S. Feb. 10, 1731; one of the first council, under their charter, in 1751; vice-president and F.R.S. June 3, 1731. He prevailed on Mr. Kirby, painter of Ipswich, to make drawings of a great number of monuments and buildings in Suffolk, of which twelve were engraved, with a description, 1748; and others remain unpublished. On the building of Westminster-bridge he was appointed secretary to the commissioners, 1736-7; and on the establishment of the Paper-Office on the respectable footing it is at present, by the removal of the State Papers from the old gate at Whitehall to new apartments at the treasury, he was nominated the first in the commission for the care and preservation of them. In 1757 he circulated proposals for printing by subscription, *Encyclopædia; or, a rational Dictionary of Arts, Sciences, and Trade.* In 1772 he published in 4to. *Calendars of the Ancient Charters, &c.* and of the *Welsh and Scottish Rolls now remaining in the Tower of London, &c.* and in the introduction gives a judicious and exact account of our Public Records. He drew up the account of the chapel of London-bridge, of which an engraving was published by Vertue in 1748, and again by the Society of Antiquaries, 1777. His historical description of the interview between Henry VII. and Francis I. on the *Champ de Drap d'Or* from an original painting at Windsor, and his account of the paintings of the same age at Cowdray, were inserted in the third volume of the *Archæologia*, and printed separately to accom-

pany engravings of two of these pictures by the Society of Antiquaries, 1775. His account of the body of Edward I. as it appeared on opening his tomb, 1774, was printed in the same volume p. 376. His intimate acquaintance with every part of Westminster Abbey displayed itself in his accurate description of five monuments in the choir, engraved in 1779 by the same society. He superintended the new edition of Leland's *Collectanea*, in nine vols. 8vo.; and also of the *Liber Niger Scaccarii*, in two vols. 8vo.; to each of which he added a valuable appendix. He also revised an edition of Hearne's *Curious Discourses*, 1771, two vols. 8vo.; and the *Registrum Roffense*, published by Mr. Thorpe, in 1769, folio. At the beginning of the seventh volume of Somers's *Tracts* is advertised A Collection of Debates in Parliament before the Restoration, from MSS. by Sir Joseph Ayloffe, bart. which is supposed never to have appeared. Sir Joseph died at his house at Kennington-lane, Lambeth, April 19, 1781, aged seventy-two.

AYMAR (James), a celebrated impostor, born at Veran, in Dauphine. He became famous, and acquired considerable wealth about the end of the seventeenth century, by giving out that he was in possession of a divining rod for bringing to light hidden treasure. The cheat was detected, and he was suffered to fall back into his former obscurity; but the noise he had raised gave occasion to De Vallemont's learned book on the powers of the *divining rod*, which see.

AYMARES, a district of Peru, forty leagues south-west of that city, abounding in sugar, cattle, corn, and mines of gold and silver.

AYMON (John), a Roman Catholic priest of Piehnout, who took part with the Protestant cause, and afterwards returned to the Catholic faith. Cardinal de Noailles gave him a pension, and he wrote several books in opposition to the Reformers. He likewise published the letters of Cyril Lucar, *Les Synodes nationaux des Eglises reformées de France*, 1710, 2 vols. 4to.; and *Tableau de la Cour de Rome*, 1710, 12mo.

AYOQUANTOTOTI, or **AVIS AYOQUANTOTOTI**, in ornithology, the name under which the otobus xanthomus of Gmelin is described by some old writers.

AYORA, a town of Spain, in Valencia. Long. 16° 40' E., lat. 39° 5' N.

AYR, or **AIR**, in Scotland. See **AIR**.

AYR, or **AIR**, a river of France, in the duchy of Bar, which abounds in fish, and falls into the Aisne, near Grandpré, in the department of the Ardennes.

AYRES, an English penman of the seventeenth century. He was employed in the service of Sir William Ashurst, in 1694, to whom he dedicated a treatise, entitled *Arithmetic made Easy*. In 1695 he published his *Tutor to Penmanship*, engraved by John Strutt. He lodged at the Hand-and-Pen, St. Paul's Church-yard, where he probably kept a school.

AYRMIN, or **AYRMEN** (William), a bishop of Norwich in the reigns of Edward II. and III. was descended of an ancient family at Osgodby in Lincolnshire. He was a canon in the cathedral of York, and afterwards in that of Wells; and was for some time keeper of the seal, and

vice-chancellor to king Edward II. under John, bishop of Norwich. About A. D. 1319, a war having broke out between England and Scotland, Ayrmyn was taken prisoner in a battle between the Scotch and Yorkists. Recovering his liberty he was made chancellor under Edward III. and afterwards treasurer. Being sent ambassador to the court of Rome, he neglected the business of his embassy, and employed his time and interest in obtaining the bishopric of Norwich, which was then vacant; in which application meeting with success, he returned to take possession of that see: which the king hearing, and being disgusted at his proceedings, sent soldiers to Norwich to apprehend him; but Ayrmyn lay hid in the cathedral church, till by the interposition of friends the king was reconciled to him, and consented to his consecration. He died in 1337.

AYR-MOSS, a place in the parish of Auchinleck in Ayrshire, memorable for a defeat of a party of those friends of religion and liberty, called Covenanters, during the turbulent and oppressive reign of Charles II.

AYRON, a river of Wales, in Cardiganshire.

AYR-SHIRE. See **AIR**.

AYRTON (Edmund), was born at Ripon, Yorkshire, in the year 1734, and died in 1808. At the age of thirty he became one of the gentlemen of the Chapel Royal, St. James's, and subsequently a vicar choral of St. Paul's and Westminster Abbey. In 1784 he took his degree of doctor of music in the university of Cambridge, on which occasion he composed a grand anthem for a full orchestra, afterwards performed at St. Paul's Cathedral, on the day appointed for the general thanksgiving for peace in 1784. Dr. Ayrton took a leading part in the commemoration of Handel in Westminster Abbey.

AYRY, or **EYERY**. **Ey**, Teutonic, an egg; **eyr**, eggs; the **eyery**, or **eggery**, where the eggs are deposited. Used of hawks, or other birds.

Yon sun-bred ayry, whose immortal birth

Bears you aloft beyond the sight of earth.

The heaven-touch'd feathers of whose sprightly wings

Skirts (from above) the palaces of kings.

Drayton. The Owl.

The eagle and the stork

On cliffs and cedar tops their *eyries* build.

Milton. Paradise Lost, book vii.

I should discourse on the brancher, the haggard,

and then treat of their several *ayries*.

Walton's Angler.

AYSCOUGH (George Edward), only son of Dr. Ayscough, dean of Bristol, was a lieutenant in the guards. He wrote *Semiramis*, a tragedy; and *Letters from an officer in the guards to his friend in England*; containing some accounts of France and Italy, 8vo. 1778. He died October, 1779.

AYSCUE (Sir George), a gallant English admiral, descended from a good family in Lincolnshire. He was knighted by Charles I., which however did not withhold him from adhering to the parliament in the civil war: he was by them constituted admiral of the Irish seas, where he did great service to the protestant interest, and contributed much to the reduction of the island.

In 1651 he reduced Barbadoes and Virginia, then held for the king, to the obedience of the parliament; and soon after the Restoration behaved with great honor in the war with the Dutch. In the famous engagement in the beginning of June 1666, when Sir George was admiral of the white squadron, his ship, the Royal Prince, ran upon Galloper sand; where, being surrounded with enemies, his men obliged him to strike. He went no more to sea after this, but spent the rest of his days in retirement.

AYSEAU, a castle and marquise of the Netherlands, in Hainault, on the Dender.

AYSERIUS, or ASSERIUS. See ASSER.

AYTONIA, in botany, a genus of the monadelphia order, and the pentandria class of plants; the characters of which are: the calyx is quinquepartite; the corolla consists of four petals; the berry is dry, quadrangular, unilocular, and many seeded. There is but one species, viz. *A. Capensis*, a native of the Cape.

AYUTLA, a river of South America, in the province of Guatimala, which flows into the Pacific Ocean. Lat. 14° 55' N.

AZAB, a place on the coast of Abyssinia, in lat. 13° N., where Bruce says 'he found the remains of a very ancient aqueduct.' He supposes it to be the Sabæ of Strabo; and the country of the Sabæ so famous for their myrrh and frankincense. 'Those gums,' he adds, 'are still produced in the neighbourhood.' Behind are pits of rock salt, whence the pieces used as coin by the Abyssinians are extracted. See Bruce, vol. i. *Strabo*. xvi. *Diod.* iii.

AZAB, in the Turkish armies, a distinct body of soldiery who are great rivals of the Janissaries. In the oriental languages the word signifies an unmarried person; the original rule being—that this corps should be composed of single men.

AZABE KABERI, from kabir, sepulchre, and azab, torment, denotes a temporary punishment, which, as the Mahomedans say, the wicked must suffer after death. Their crimes are hereby expiated, and Mahomet opens the gate of Paradise to all who believe in him.

AZALDUS, in old law Latin, a sorry horse.

AZALEA, AMERICAN UPRIGHT HONEYSUCKLE, a genus of the monogynia order, and pentandria class of plants; ranking, in the natural method, under the eighteenth order, bicornes. The corolla is bell-shaped; the stamina are inserted into the receptacle; and the capsule has five cells. There are six species, of which the most remarkable are the following: 1. *A. nudiflora*, or red American upright honeysuckle, grows taller than the *viscosa*, and in its native country will sometimes arrive at the height of twelve feet, but in Britain never rises to above half that height. It has several stems with oblong smooth leaves. 2. *A. rubriflora*, a species with bright red flowers, was found by Mr. Lightfoot upon the tops of many mountains in the Highlands of Scotland. 3. *A. viscosa*, with a white flower, is a low shrub, arising with several stems to the height of two or three feet. The leaves come out in clusters without any order at the end of the shoots, and their edges are set with very short teeth which are rough. The flowers come out in clusters between the leaves,

have much the appearance of honeysuckle, and are as well scented.

AZAMOR, a small sea-port town of the kingdom of Morocco in Africa. It is situated on the river Morbeya, in the province of Duquella, at some considerable distance from its mouth. This town, though formerly very considerable, is obstructed in its maritime commerce by the dangerous entrance of the river. It was unsuccessfully besieged by the Portuguese in 1508; it was taken however, in 1513, by the duke of Braganza, but abandoned about the end of the sixteenth century. Mr. Jackson calculates its population at 1000. It is eighty miles north of Morocco.

AZARADEO, a sea-port town of Brasil, in the bay of Spiritu Santo. Long. 60° 10' W. lat. 20° 18' S.

AZARAKITES, a sect of Mahomedan Arabs.

AZARECAH, a sect of heretical Mussulmans who acknowledged no punishment, temporal or spiritual.

AZARIAH; from *עזר*, and *יה*, i. e. the help of the Lord; king of Judah. See UZZIAH. Also the name of various high priests and princes of the Jews.

AZARIAS, a Jewish rabbi and historian of the sixteenth century. In 1574 he published at Mantua, in Hebrew, a book entitled *The Light of the Eyes*. Many historical and miscellaneous subjects are treated of in this work; and it contains a Hebrew version of the letter of Aristæus on the Septuagint.

AZARIST, a city of Khieva, on the river Amo which was visited by the English factors in 1741.

AZAROLA, the service tree.

AZARUM, a small, dry, blackish, stringy, medicinal root, much used in France as a specific for the farcy in horses. The azarum, called also *nardus sylvestris*, grows in the Levant, Canada, and about Lyons in France. The first is reputed the best. It is given in powder, from the quantity of one ounce to two.

AZAY, or ASSAIE-LE-RIDEAU, a town of France, in the department of the Indre and Loire, situated on the Indre, the head of a canton, with a castle, and 1700 inhabitants. It was in former times a place of strength, and the seat of a royal governor. Five leagues south-west of Tours.

AZAY-SUR-CHER, a town in France, situated on the river Cher, and belonging to the arrondissement of Tours, in the department of the Indre and Loire. Number of houses above 230. Two leagues and a half E. S. E. of Tours. Many other villages and hamlets in France bear this name.

AZAZEL, a word relating to the institution of the scape-goat, in the Jewish religion, respecting which there are various opinions. St. Jerome and Theodoret call the goat itself by this name. Dr. Spencer says the scape-goat was to be sent to Azazel, by which is meant the devil. M. le Clerc translates it *præcipitium*, making it to be that steep and inaccessible place to which the goat was sent, and where it was supposed to perish.

AZED, in the materia medica, a name given by the Arabian writers to a kind of camphor, which they make the third in value, placing it

after the alcansuri and abriagi. The first of these was the finest of all the kinds of camphor, and was collected tolerably pure from the tree, as it grew in Cansur, the place whence it was named. The second was the same camphor, rendered yet more pure by sublimation; this was a discovery of one of the kings of that country, and the camphor was named from him. The third kind, or azed, was the same with what we now receive from the Indies, under the name of crude or rough camphor. The word azed signifies only large, and was used to express the camphor formed into large cakes. Avicenna says this camphor was gross, of a dusky color, and much less bright and pellucid than the other kinds.

AZEDARACH, or **AZERADACH**, in botany, the bead-tree.

AZEEMABAD, the Mahomedan name of **PATNA**, which see.

AZEITAO, a town in Portuguese Estremadura, south of the Tagus, with a manufacture of chintz, and various dye-houses. Population 2350. Five miles N. N. W. of Setuval.

AZEKAH, in ancient geography, a city of the Amorites, in the lot of Judah; situated between Eleutheropolis and Aelia; where the five kings of the Amorites and their army were destroyed by hail.

AZELBURG, a town of Bavaria, formerly called Augusta ACILIA.

AZELFOGE, in astronomy, a fixed star of the second magnitude, in the swan's tail.

AZEM, **ASFM**, **ASSAM**, or **ACHAM**, a country of Asia, north of Ava. See **ASSAM**.

AZEMAFOR, in alchemy, red lead.

AZEMECH, the Arabian name for the star, called the virgin's spike.

AZENAY, a town of France, in Poitou, department of the Vendee, arrondissement of Sables d'Olonne. Population 3000. Five leagues north of Sables d'Olonne.

AZERBIJAN, or **ADERBEITZAN**, a province of Persia, part of the ancient Media, bounded by Ghilan and the Caspian sea on the east, and on the west by Kurdistan and Armenia. It is separated from the latter by the Araxes, and from the province of Irak on the south, by Kizilozéin, or the Golden stream. The climate, which is generally temperate, is cold in winter, and severely felt by the poorer inhabitants, from the scarcity of fuel. The province is watered by the two rivers already named, and by the Jungatty, which is larger than either, and abounds in fish; the Yezdian, Agi, and other lesser streams. On the frontier also is the lake Urumea, which is saltier than the sea. Its minerals are lead, copper, saltpetre, and sulphur; here is also a kind of beautiful transparent marble, or jasper, which takes the highest polish, and is used in the buildings of Tabriz, Shiraz, and Ispahan, under the name of Tabriz marble. The cultivation of the land, which consists of fine undulating eminences and rich valleys, is here carried on chiefly by irrigation; the oxen are used for the plough, and the best soil yields from fifty to sixty fold. Most of the villages are surrounded with orchards and gardens, which produce fruit of almost every description. A considerable quantity of wine is made; and provisions are cheap and abundant.

The name of this province is said to signify the country of fire, and is supposed to have been derived from the number of fire temples of the Guebres. It is divided into twelve districts, in which are several cities and towns of importance, as Tabriz, or Tauris, the capital, containing 30,000 inhabitants, Urumea, Shebuster, and Maragah.

AZERGUE, **BAHR-EL**, or the **BLUE RIVER**, the principal stream of Abyssinia, which, rising in the kingdom of Gojam, passes through the lake of Dembea, and, after a winding course through Abyssinia and Sennaar, falls into the Nile above Gerri. Travellers described it the principal branch of the Nile, till D'Anville showed that this distinction belonged to the Bahr-el-Abiad.

AZEVEDO (Ignatius), a Portuguese jesuit, born in 1527. He was heir to a handsome fortune, but turned his back upon it for a religious life, and went as a missionary to India. In 1570 he was going out a second time, when the ship was taken by pirates, who killed all the missionaries, about forty in number.

AZIMEN, in astrology, certain degrees in the zodiac, which, when they are ascendant, persons born under them are said to be afflicted with lameness, or some other imperfection.

AZIMUTH, in astronomy, an arch of the horizon, intercepted between the meridian of the place and the azimuth, or vertical circle passing through the centre of the object, which is equal to the angle of the zenith, formed by the meridian and vertical circle. It is found by this proportion: As the radius to the tangent of the latitude of the place, so is the tangent of the sun's or star's altitude, for instance, to the cosine of the azimuth from the south, at the time of the equinox.

AZIMUTH CIRCLES are represented by the rhumbs on common sea charts, and on the globe they are represented by the quadrant of altitude, when screwed in the zenith. On these azimuths is reckoned the height of the stars and of the sun when not in the meridian.

AZIMUTH COMPASS, an instrument for finding either the magnetical azimuth or amplitude of an heavenly object. The learned Dr. Knight invented some time ago a very accurate and useful sea-compass, which is at present used in the navy, and will be found described under the article **COMPASS**. This instrument, with the following contrivance added by the ingenious Mr. Smeaton, answers the purposes of an azimuth and amplitude compass. The cover of the wooden box being taken off, the compass is in a condition to be made use of in the binnacle, when the weather is moderate; but if the sea runs high, as the inner box is hung very free upon its centre, the better to answer its other purposes, it will be necessary to slacken the milled nut, placed upon one of the axes that support the ring, and to lighten the nut on the outside that corresponds to it. By this means, the inner box and ring will be lifted up from the edges upon which they rest when free, and the friction will be increased, and that to any degree necessary to prevent the too great vibrations which otherwise would be occasioned

by the motion of the ship. To make the compass useful in taking the magnetic azimuth or amplitude of the sun and stars, as also the bearings of headlands, ships, and other objects at a distance, the brass edge, designed at first to support the card, and throw the weight thereof as near the circumference as possible, is itself divided into degrees and halves, which may be easily estimated into smaller parts if necessary. The divisions are determined by means of a catgut line, stretched perpendicularly with the box, as near the brass edge as may be, that the parallax, arising from a different position of the observer, may be as little as possible. Underneath the card are two small weights, sliding on two wires, placed at right angles to each other; which being moved nearer to, or farther from, the centre, counterbalance the dipping of the card in different latitudes, or restore the equilibrium of it where it happens by any other means to be too much out of level. There is also added an index at the top of the inner box, which may be put on and taken off at pleasure; and serve for all altitudes of the object. It consists of a bar, equal in length to the diameter of the inner box, each end being furnished with a perpendicular stile, with a slit parallel to the sides thereof: one of the slits is narrow, to which the eye is applied; and the other is wider, with a small catgut stretched up the middle of it, and from thence to the top of the other. There is also a line drawn along the upper surface of the bar. These four, viz. the narrow slit, the horizontal catgut thread, the perpendicular one, and the line on the bar, are in the same plane which disposes itself perpendicular to the horizon, when the inner box is at rest and hangs free. This index does not move round, but is always placed on so as to answer the same side of the box. When the sun's azimuth is desired, and his rays are strong enough to cast a shadow, turn about the wooden box till the shadow of the horizontal thread, or, if the sun be too low, till that of the perpendicular thread, in one stile, or the light through the slit on the other, falls upon the line in the index bar, or vibrates to an equal distance on each side of it, gently touching the box if it vibrates too far: observe, at the same time, the degree marked upon the brass edge by the catgut line. In counting the degree for the azimuth, or any other angle that is reckoned from the meridian, make use of the outward circle of figures upon the brass edge; and the situation of the index bar, with regard to the card and needle, will always direct upon what quarter of the compass the object is placed. But if the sun does not shine out sufficiently strong, place the eye behind the narrow slit in one of the stiles, and turn the wooden box about, till some part of the horizontal or perpendicular thread appears to intersect the centre of the sun, or vibrate to an equal distance on each side of it, using smoked glass next the eye if the sun's light is too strong. In this method another observer will be generally necessary, to note the degree cut by the nonius, at the same time that the first gives notice that the thread appears to split the object. The other observations will be easily performed: only, in case of the sun's amplitude, take care to number the degree by the help of the inner circle of figures on the card,

which are the complement of the outer to 90° and, consequently, show the distance from east to west. The azimuth of the stars may also be observed by night; a proper light serving equally for one observer to see the thread, and the other the degree upon the card. It may not be amiss to remark farther, that in case the inner box should lose its equilibrium, and consequently the index be out of the plane of a vertical circle, an accurate observation may still be made, provided the sun's shadow is distinct; for, by observing first with one end of the index towards the sun, and then the other, a mean of the two observations will be the truth.

AZIMUTH DIAL, a dial whose gnomon is perpendicular to the plane of the horizon.

AZIMUTH, MAGNETICAL, an arch of the horizon intercepted between the azimuth, or vertical circle, passing through the centre of any heavenly body, and the magnetical meridian. This is found by observing the object with an azimuth compass.

AZINCOURT, or AGINCOURT. See **AGINCOURT**.

AZLEEL, the name of an angel mentioned in the book ascribed to Enoch.

AZMUT, or ASMUS, an ancient and large town of Natolia, eighty-four miles south-east of Scutari. It is inhabited by Greek christians.

AZO, a town of Asia in the East Indies, seated on the frontiers of Azem, on the river Laquia.

Azo I. and II. earls of Este in Italy, in the tenth century. They claimed their descent from the Accii, a patrician family of ancient Rome. Their posterity settling afterwards in Germany, gave rise to the illustrious house of Brunswick; from which that of Hanover and the present royal family of Great Britain are lineally descended.

AZOF, or Azov, a town and fortress of Russia, in the government of Yekatorinoslaw, at the mouth of the Don; lat. $46^\circ 53' N.$, long. $39^\circ 14' E.$ When Dr. Clarke saw it in 1800, it did not contain more than fifty houses; the garrison consisted of a few worn-out invalids, and the works were abandoned to decay. It is surrounded by a swamp; and the interior of the country is a barren desert. It was anciently a considerable port; but the waters of the bay have been diminishing for many years. Tanais is mentioned by Strabo, as a settlement of the Bosphorani, but Dr. Clarke could find no trace of the ancient town near the site of Azov, and supposes it must have been at the embouchure of the Danaetz or northern arm of the Don. Its ancient history is very obscure; but it passed from the Polovtzes to the Genoese, who called it *la Tana*; was wrested from them by Tamerlane in 1392; and possessed, after his decease, by the khans of the Krim till 1471, when it fell into the hands of the Turks. Peter the Great took it by assault, and laid out large sums upon improving its fortifications, but was obliged to give it up at the peace of 1711. The fortifications were demolished, in compliance with the terms made at the peace of Belgrade in 1739; but it was finally ceded to Russia in 1774.

The sea of Azof, named from the above town, was the *Palus Mæotis* of the ancients, and the *Mar de Zabacchi* of the middle ages. It is 210 miles long, and about fifty broad; though pro-

perly only a bay of the Black sea, with which it is united by the straits of Caffa (Keffeh). Its principal port is Taganrok. Its fish are small, but plentiful; so that 60,000 are often taken at one draught. This sea seems to be gradually filling up with the alluvial earth brought down by the Don; and, during violent east winds, the waters are driven so far back, where it is from thirteen to fourteen miles broad, as to allow a passage over the sand from Jagan Rock to the opposite coast. But when the wind changes the water flows back with such rapidity, that many of those who have attempted to cross this temporary route are overwhelmed by the returning tide. The deepest soundings are from thirty-five to forty feet. The whole surface, except a portion towards the centre, freezes during about a month in winter. A new island, at some distance from the shore, was thrown up on the 5th of September, 1799, with phenomena evidently volcanic.

AZOGA SHIPS, are those Spanish ships commonly called the quicksilver ships, from their carrying quicksilver to the Spanish West Indies, to extract the silver out of the mines of Mexico and Peru. These ships are prohibited to carry any goods except for the king of Spain.

AZOGUES, a town of Quito, South America, ten miles north-east of Cuenca.

AZOLO. See **ACELUM**.

AZONI; from *a* privative, and *Zorn*, country; in mythology, a term anciently applied to such of the gods as were not the private divinities of any particular country, but were acknowledged in every country, and worshipped by every nation. They were superior to the gods called *zœni*, who were supposed to inhabit particular parts of the world, and never to stir out of the district or zone that was assigned them. Such in Egypt were Serapis, Osiris, and Bacchus; and in Greece, the Sun, Mars, the Moon and Pluto. They were called by the Romans *dii communes*.

AZOOPIHAGUS; from *a*, *ζωον*, animal, and *φαγω*, to eat; in natural history, a term used by authors to express such insects or animals as feed on herbs, never eating the flesh of any living creature.

AZORES, or **WESTERN ISLANDS**, a group of islands in the Atlantic Ocean, situated between the thirty-seventh and fortieth degrees of latitude, and about 800 miles from the western shore of Portugal. The name is said to have been given to them on their first discovery by the Portuguese, from Acor, a falcon, on account of the numerous goshawks which they found there. They have also sometimes been called *Terceiras*, from the principal island. The Azores still belong to the crown of Portugal, and are considered as forming three separate clusters. St. Mary and St. Michael lie at the eastern extremity; the five islands of Terceira, Graciosa, St. George, Pico, and Fayal, form a central group; while Corvo and Flores are more detached, and lie farther north-west. The geographers of Arabia, in the middle ages, appear to have had some knowledge of these islands; but they were not known to Europeans till towards the middle of the fifteenth century, when Vander Berg, a Flemish merchant, being driven by contrary winds on

these shores, and intelligence of the event reaching the court of Lisbon, an expedition was fitted out to take possession of them. The Flemings took possession of L'ayal, where traces of them are still visible. When Portugal became subject to the Spanish yoke in 1580, these islands fell under Spanish control till the duke of Braganza was raised to the throne in 1640. They were now for a long period much neglected by the home government; but their situation being most salubrious, and highly favorable to commerce, they encreased and prospered spontaneously. Towns and cities were founded, and the population rose to between 200,000 and 300,000.
